Essentials of MEDICAL MICROBIOLOGY

The novel feature of the book is its clinically relevant approach to microbiology

- **More content, less pages—handy look, saves a student's time**
- **Bulleted format in concise, simple and lucid language**
- **Summary boxes for lab diagnosis and treatment—for quick review**
- **Over 600 figures (images/line diagrams) and 300 tables/flow charts incorporated**
- **Clinical case-based essay questions and MCQs incorporated**

Our Beloved Parents, Family Members

And, above all, the Almighty

When one door of happiness closes, another opens; but often we look so long at the closed door that we do not see the one which has been opened for us.

— **Helen Keller**

Foreword

Few decades back, there were hardly any books on Medical Microbiology written by Indian authors. With expansion of medical education in the country over the years, the undergraduate students' population has grown significantly and there is an intensely felt need for books to suite the students' choices with regards to style, presentation, language and content. It is in this backdrop that we have to visualize the birth of a good number of Indian books in the recent past.

Most of these books are authored by teachers who have spent considerable time in teaching microbiology in medical colleges. However, here we have a couple of young enthusiastic passionate teachers of microbiology, who have taken pains to put their thoughts in the shape of a wonderful book. Though this book looks like another book in the field, but certain features, like the updated matter, lucid presentation style, useful pictures and clinical case-based discussions are unique to this book.

I am sure that many students would relish to go through this book and get benefited. The information provided might become handy for postgraduate students as well, even though they cannot fully depend on this.

I really appreciate the efforts made by my colleague Dr Apurba Sankar Sastry and his wife Dr Sandhya Bhat K for this commendable work.

Dr BN Harish MD

Foreword

Essentials of Medical Microbiology by Dr Apurba Sankar Sastry and Dr Sandhya Bhat K comes at a time when several Microbiology books are being written and published in the country. We have come a long way from the time the students had to depend on one or two textbooks in microbiology which were published in India to the current time where the choice is varied, to pursue the course.

This book has many advantages over other textbooks in microbiology in being a concise, easy-to-read book, which can be used both as a textbook for an undergraduate MBBS course as well as a handbook for easy reference for microbiology examinations. Chapters range from *General Microbiology*, which addresses the basic concepts in microbiology, to schematically represented easily comprehensible immunology. New concepts in immunology and details of cells and cellular products have been lucidly explained with the help of diagrams. *Bacteriology* has been written with a clinical approach to make it relevant to a student in the clinical years. Several infections have been supported with clinical pictures and images. *Virology* also follows a similar trend with updated information on recent outbreaks, epidemics and emerging infections.

The book will be useful for students preparing for examinations, both formative assessments and the final summative examination. An additional attraction is the orientation for postgraduate entrance examination. The students will find the book very handy. The authors must be congratulated on their continuous efforts to bring forth textbooks for students of microbiology.

Reba Kanungo MD PhD
Dean–Research and Professor and Head
Department of Clinical Microbiology
Pondicherry Institute of Medical Sciences (PIMS)
Puducherry, India
Past President, Indian Association of Medical Microbiologists
Former Editor-in-Chief, Indian Journal of Medical Microbiology

Preface

The association of man and microorganisms, and their fight to survive each other is never-ending. With the increasing complexity of interaction between man and microbes, the relevance of studying medical microbiology has increased manifold. Our book titled, *Essentials of Medical Microbiology* attempts to provide smart ways to master the world of microbes relevant to the mankind.

The idea of yet another book on the subject, but with a quite different approach was born after several discouraging and unsatisfying experiences with several existing books regarding many needs of the enthusiastic students of the subject and a strong desire to make medical microbiology more interesting, up-to-date, clinically relevant and yet palatable to mainly undergraduate students of medicine and also the postgraduate aspirants and students. This book was conceptualized and brought to reality to meet the strongly felt diverse needs of the Indian students, such as gaining essential concepts, acquiring contemporary knowledge, approaching university exams with ease and confidence, scoring high in postgraduate entrance examinations, etc.

The book focuses on providing good foundation in clinically important concepts and principles of microbiology. Enough (over 300) tables and flow charts have been included along with the text. Over 200 schematic diagrams have been drawn to simplify difficult concepts, and they are easy to reproduce where necessary as in examinations. Plenty of clinical photographs (over 400) included in the book will create a real life-like picture in the minds of the reader and also are meant to help solving image-based MCQs in postgraduate entrance examinations. It has more content in fewer pages, making the book handy. The concise bulleted format and to-the-point text used in this book will be helpful in rapid revision before the examinations. Best attempts have been made to keep the language simple yet lucid to help easy comprehension. Summary of laboratory diagnosis and treatment in separate boxes makes quick review possible. Highlighted boxes are incorporated to cover the important concepts. In a nutshell, this book is carefully written targeting to meet the varied needs of undergraduate students with an approach that will orient them to build concepts and to clear undergraduate examinations as well as to equip them for postgraduate entrance examinations in future.

General Microbiology section deals with principles of microscopy, morphology, physiology, culture identification of bacteria, concepts of bacterial genetics, etc. Principles of sterilization, antimicrobial chemotherapy and susceptibility testing are also explained in detail.

It is our humble hope that this book would change the general feeling of the students regarding immunology as being a difficult section into immunology as an interesting and enjoyable topic. In this section, topics such as *immunity*, *antigen*, *antibody*, *complement* and *structure of immune system* are explained in a simple and logical manner. Chapters like *immune response* and *antigen-antibody reaction* have been fully updated according to the current need. Appropriate diagrams and flow charts are incorporated to make critically tough content easy to grasp. Topics such as *autoimmunity*, *immunodeficiency* and *immunization* provide complete and latest information compiled in tabular form at one place.

Systematic Bacteriology section deals with individual bacterial pathogens in detail. Flow of information follows a very logical and clinically relevant course. More stress is given to the knowledge that helps in clinical setting and a careful attempt has been made to reduce the obsolete and not-so-useful core microbiology content. Sections like *laboratory diagnosis*, *treatment* and *prophylaxis* are most updated and referenced from internationally accepted literature and guidelines.

Virology is another section where the readers will find a different approach from the existing books. The updated and succinct information provided in this section with emphasis on *pathogenesis* and *laboratory diagnosis* will be useful to the students.

This book also addresses to the long-time complaint of the undergraduate students about unavailability of a concise and pictorialized *Mycology* section. Written in a clear and concise manner with appropriate and beautiful schematic pictures, images and illustrations, this section will surely make the students enjoy reading.

Applied Microbiology covers important aspects of various clinical infective syndromes with special reference to the approach towards the diagnosis. Useful information regarding hospital-acquired infections and biomedical waste management have been incorporated. The annexure incorporated at the end covers the recent topics, such as *emerging pathogens*, *bioterrorism* and *laboratory-acquired infections*.

Clinical case-based essay questions and MCQs are given at the end of each chapter to orient and prepare students for the examinations. Advanced and newer postgraduate entrance-oriented topics like H1N1, ebola, polio eradication, bacterial drug resistance mechanisms (such as ESBL, VRSA, VRE), automations and molecular methods in microbiology, etc. are incorporated.

We hope that the undergraduates, postgraduate aspirants, and postgraduate students will relish reading this book and find it useful. We also hope that we have made a good start in addressing the varied needs of students and faculty teaching medical microbiology with a single comprehensive book. We will feel glad to receive your valuable feedback, which will enable us to improve further.

Acknowledgments

Acknowledgment for contributing towards the figures

We are extremely thankful to the people/institutes/companies who have agreed to provide valuable photographs.

Sincere acknowledgments for helping in manuscript preparation

- Dr Anand Janagond, Associate Professor, Department of Microbiology, Velammal Medical College, Madurai, Tamil Nadu, India, co-editor of the book, for helping in the correction of the manuscript.
- Dr S Sujatha, Professor, Department of Microbiology, JIPMER for her valuable suggestions during the manuscript preparation.
- Dr Noyal M Joseph, Assistant Professor, Department of Microbiology, JIPMER for his useful inputs during the manuscript preparation.

Special acknowledgments to my publishers

Jaypee Brothers Medical Publishers (P) Ltd.

- Shri Jitendar P Vij (Group Chairman)
- Mr Ankit Vij (Group President)
- Mr Tarun Duneja (Director–Publishing)
- Ms Seema Dogra (Senior Designer)
- Dr Sakshi Arora (Director–Development and Content Strategy), Ms Nitasha Arora (Project Manager) and her team
  - Mr Phool Kumar, Mr Bunty Kashyap, Mr Vikas Kumar, Mr Puneet Kumar, Mr Parbhat Ranjan, Mr Iqbal, Mr Sandeep Kumar, Mr Sanjeev Kumar, Mr Neeraj Choudhary, Ms Neelam, Ms Sonal Jain, Ms Ankita Singh and Mr Prashant Soni (Development Team).
  - It was a lifetime memorable week for me working with this team. These guys are simply the best. They are extremely workaholic and have a very good team spirit. I salute them for their professionalism.
- Staff from other branch office: Mr Venugopal (Bengaluru Branch), Mr Suresh and Mr Sharma (Hyderabad Branch), Mr Senthil Kumar (Chennai Branch), Mr Muralidharan (Puducherry Branch), Mr CS Gawde (Mumbai Branch), Mr Sandip Gupta and Mr Sanjoy Chakraborty (Kolkata Branch) and Mr Vasudev H (Mangalore Branch).

Hearty acknowledgments to the departmental staff and relatives for their blessings and support

- We would like to sincerely thank Dr BN Harish, Senior Professor and Head, Department of Microbiology, JIPMER, for giving the foreword.
- We are extremely thankful to Dr Reba Kanungo, Dean Research, Professor and Head, Department of Microbiology, Pondicherry Institute of Medical Sciences (PIMS) for giving the foreword.
- Dr Subhash Chandra Parija, Director, JIPMER and Former Head, Department of Microbiology, JIPMER.
- Dr John Abraham, Director-Principal, Pondicherry Institute of Medical Sciences (PIMS).
- Other faculty of JIPMER, Microbiology—Dr Jharna Mandal (Associate Professor), Dr Rakesh Singh (Associate Professor), Dr Rahul Dhodapkar (Associate Professor) and Dr Nonika Rajkumari (Assistant Professor).
- Pondicherry Institute of Medical Sciences (PIMS), Microbiology Faculty—Dr Shashikala (Professor), Dr Sheela Devi (Professor) and other faculty members.
- JIPMER, Department of Microbiology–Residents, MSc, PhD scholars and others.
- PIMS, Department of Microbiology–PG students and others.

- Meenakshi Medical College, Chennai, Tamil Nadu, India, Department of Microbiology staff—Dr Amshavathani (Professor and HOD), Dr Senthamarai (Professor), Dr Sivasankari (Associate Professor), Dr Kumudavathi (Tutor) and Dr Anitha (Assistant Professor).
- ESIC Medical College and PGIMSR, Chennai, Tamil Nadu, India, Department of Microbiology staff—Dr Manisha S Mane (Associate Professor) and others.
- Sri Siddhartha Medical College, Tumkur, Karnataka, India (All faculty members, Department of Microbiology).
- Our friends—Dr Godfred, Dr Sadia, Dr Ramakrishna, Dr Neelesh, Dr Srinivas, Dr Chhaya, Dr Manisha, Dr Ira and others.
- All maternal and paternal relatives and cousins.
- Last but not the least, we want to thank our parents—Mr Ganesh Bhat and Mrs Shakunthala Bhat for their continuous support throughout the journey of the manuscript preparation and bestowing all their blessings.

Contents

Section 1 General Microbiology

1. Introduction and Bacterial Taxonomy 3
2. Morphology and Physiology of Bacteria 9
3. Sterilization and Disinfection 30

Section 3 Systematic Bacteriology

Gram-positive cocci

21. *Staphylococcus* 211
22. *Streptococcus*, *Enterococcus* and Pneumococcus 221

Gram-negative cocci

23. *Neisseria* and *Moraxella* 236

Gram-positive bacilli

24. *Corynebacterium* 243
25. *Bacillus* 250

26. Anaerobes (*Clostridium* and Non-sporing Anaerobes) 256
27. Mycobacteria 271
28. Miscellaneous Gram-positive Bacilli 292

Gram-negative bacilli

29. Enterobacteriaceae-I 298
30. Enterobacteriaceae-II: *Salmonella* 317
31. *Vibrio* and *Aeromonas* 328
32. *Pseudomonas* and other Non-fermenters 339
33. *Haemophilus* and HACEK Group 345
34. *Bordetella* 351
35. *Brucella* 355
36. Miscellaneous Gram-negative Bacilli 361

Other groups of bacteria

37. Spirochetes 371
38. Rickettsiae, *Coxiella*, *Bartonella* 388
39. Chlamydiae 397
40. *Mycoplasma* and *Ureaplasma* 405

Section 4 Virology

41. General Properties of Viruses 411

DNA viruses

42. Herpesviruses 433
43. Other DNA Viruses 446

RNA viruses

44. Myxoviruses and *Rubella* Virus 457
45. Picornaviruses 475
46. Arboviruses 483
47. Rhabdoviruses 496
48. HIV and Other Retroviruses 503
49. Miscellaneous RNA Viruses 517

Other groups of viruses

50. Hepatitis Viruses 527
51. Oncogenic Viruses 542

Section 5 Mycology

52. Medical Mycology 549

Section 6 Applied Microbiology

53. Normal Microbial Flora of Human Body 581
54. Clinical Microbiology (Infective Syndromes) 585
55. Hospital Acquired Infections 606
56. Biomedical Waste Management 612
57. Bacteriology of Water, Milk, Air and Food 615

Annexures

1. Emerging and Re-emerging Infections 625
2. Bioterrorism 627
3. Laboratory Acquired Infections 629
4. Zoonosis 630

CHAPTER 1

Introduction and Bacterial Taxonomy

Chapter Preview

- History
- Bacterial taxonomy

Medical microbiology is a branch of medicine that deals with the study of microorganisms and their role in human health and diseases. It also concerns with the diagnosis, treatment and prevention of various infectious diseases. There are four kinds of microorganisms that cause infectious disease: bacteria, fungi, parasites and viruses. The branches of medical microbiology are as follows:

- **General microbiology:** Study of general properties of microorganisms, such as bacterial morphology, sterilization and disinfection, culture identification methods, bacterial genetics, etc.
- **Immunology:** The study of the immune system
- **Bacteriology:** The study of bacteria
- **Virology:** The study of viruses
- **Mycology:** The study of fungi
- **Parasitology:** The study of parasites; it has two arms
  - Protozoology: The study of protozoa
  - Helminthology: The study of helminths.

HISTORY

The existence of microorganisms was hypothesized for many centuries before their actual discovery. The teaching of Mahavira (Jainism, 6th century BC) and the postulation of Varo and Columella (who named the invisible organisms as '*Animalia minuta*') were some of those attempts.

CONTRIBUTORS IN MICROBIOLOGY

Antonie Philips van Leeuwenhoek (1676)

He was the first scientist who observed bacteria and other microorganisms, using a single-lens microscope constructed by him and he named those small organisms as '*Little animalcules*' (Fig. 1.1A).

Edward Jenner

Edward Jenner 1796, developed the first vaccine of the world, the smallpox vaccine. He used the cowpox virus (*Variolae vaccinae*) to immunize children against smallpox from which the term **'vaccine'** has been derived. The same principles are still used today for developing vaccines.

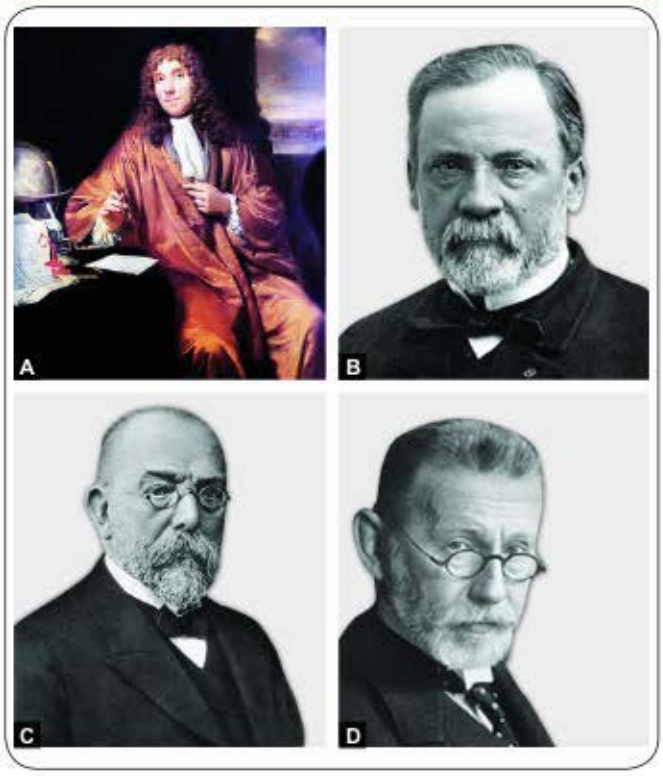
Louis Pasteur

Microbiology developed as a scientific discipline from the era of Louis Pasteur (1822–1895). He is also known as **father of microbiology**. He was a professor of chemistry in France. His studies on fermentation led him to take interest to work in microbiology (Fig. 1.1B). His contributions to microbiology are as follows:

- He had proposed the **principles of fermentation** for preservation of food.
- He introduced the **sterilization techniques** and developed steam sterilizer, hot air oven and autoclave.
- He described the method of **pasteurization of milk**.
- He had also contributed for the vaccine development against several diseases, such as anthrax, fowl cholera and rabies.
- He disproved the theory of spontaneous generation of disease and postulated the '**germ theory of disease**'. He stated that disease cannot be caused by bad air or vapor, but it is produced by the microorganisms present in air.
- **Liquid media concept:** He used nutrient broth to grow microorganisms.
- He was the founder of the Pasteur Institute, Paris.

Joseph Lister

Joseph Lister (1867) is considered to be the **father of antiseptic surgery**. He had observed that postoperative infections were greatly reduced by using disinfectants such as diluted carbolic acid during surgery to sterilize the instruments and to clean the wounds.



Figs 1.1A to D: Eminent microbiologists. **A.** Antonie van Leeuwenhoek; **B.** Louis Pasteur; **C.** Robert Koch; **D.** Paul Ehrlich

Source: Wikipedia

Robert Koch

Robert Koch provided remarkable contributions to the field of microbiology. He was a German general practitioner (1843–1910) (Fig. 1.1C). His contributions are as follows:

- He introduced **solid media** for culture of bacteria, Eilshemius Hesse, the wife of, one of Koch's assistants had suggested the use of **agar** as solidifying agents.
- He also introduced methods for isolation of bacteria in **pure culture**.
- He described hanging drop method for testing motility.
- He discovered bacteria such as the anthrax bacilli, tubercle bacilli and cholera bacilli.
- He introduced staining techniques by using aniline dye.
- **Koch's phenomenon:** Robert Koch observed that guinea pigs already infected with tubercle bacillus developed a hypersensitivity reaction when injected with tubercle bacilli or its protein. Since then, this observation was called as Koch's phenomenon.
- **Koch's postulates:** Robert Koch had postulated that a microorganism can be accepted as the causative agent of an infectious disease only if four criteria are fulfilled. These criteria are as follows:

1. The microorganism should be constantly associated with the lesions of the disease.
2. It should be possible to isolate the organism in pure culture from the lesions of the disease.
3. The same disease must result when the isolated microorganism is inoculated into a suitable laboratory animal.
4. It should be possible to re-isolate the organism in pure culture from the lesions produced in the experimental animals.

An additional **fifth** criterion was introduced subsequently which states that antibody to the causative organism should be demonstrable in the patient's serum.

Exceptions to Koch's postulates: It is observed that it is not always possible to apply these postulates to study all the human diseases. There are some bacteria that do not satisfy all the four criteria of Koch's postulates. Those organisms are:

- *Mycobacterium leprae* and *Treponema pallidum:* They cannot be grown *in vitro*; however, they can be maintained in experimental animals.
- *Neisseria gonorrhoeae:* There is no animal model; however, it can be grown *in vitro*.

Molecular Koch's Postulates

It was a modification of Koch's postulates formulated by the microbiologist Stanley Falkow (1988). He stated that gene (coding for virulence) of a pathogenic microorganism that contributes to the disease should satisfy all the criteria of Koch's postulates rather than the microorganism itself.

- The virulence trait under study should be associated much more with pathogenic strains of the species than with nonpathogenic strains.
- Inactivation of the gene associated with the suspected virulence trait should substantially decrease pathogenicity.
- Replacement of the mutated gene with the normal wild-type gene should fully restore pathogenicity.
- The gene should be expressed at some point during the infection and disease process.
- Antibodies or immune system cells directed against the gene products should protect the host.

Paul Ehrlich

Paul Ehrlich (1854–1915) was a German scientist and is also known as **father of chemotherapy** (Fig. 1.1D). His contributions are as follows:

- He was the first to report the acid-fast nature of tubercle bacillus.
- He developed techniques to stain tissues and blood cells.
- He proposed a toxin-antitoxin interaction called **Ehrlich phenomenon** and also introduced methods of standardising toxin and antitoxin.

- He proposed the '**side chain theory** for antibody production'.
- **Chemotherapy:** He discovered **salvarsan**, an arsenical compound (also called as the 'magic bullet') as the first effective medicinal treatment for syphilis, thereby initiating and also naming the concept of chemotherapy.
- The bacteria '*Ehrlichia*' was named after him.
- In 1908, he received the Nobel prize in Physiology or Medicine for his contributions to immunology.
- He was the founder and first director of what is known now as the Paul Ehrlich Institute, Germany.

Other Important Contributors

- **Hans Christian Gram** (in 1884): He developed a method of staining bacteria which was named as 'Gram stain' to make them more visible and differentiable under a microscope.
- **Charles Chamberland:** He is one of Pasteur's associates, constructed a porcelain bacterial filter in 1884 by which the discovery of viruses and their role in disease was made possible. The first viral pathogen to be studied was the tobacco mosaic virus.
- **Ernst Ruska:** He was the founder of electron microscope (1931).
- **Alexander Fleming** (in 1929): He discovered the most commonly used antibiotic substance of the last century, i.e. penicillin.
- **Goodpasture:** He described the viral culture technique in chick embryo.
- **Lady Mary Wortley Montagu:** Introduced variolation for immunizing against smallpox.
- **Elie Metchnikoff:** He described phagocytosis and termed *phagocytes*.
- **Emmy Klieneberger (1941):** She described the existence of L forms of bacteria.
- **Barbara McClintock:** She described the mobile genetic elements in bacteria called transposons.
- **Walter Gilbert and Frederick Sanger** were the first to develop (1977) the method of DNA sequencing.
- **Karry B Mullis:** Discovered polymerase chain reaction (PCR) and was awarded Noble prize in 1993.

Discovery of Bacterial Agents

Several bacteria were discovered by many scientists (Table 1.1). The names of some of the bacteria are coined in the honor of scientists who discovered them (Table 1.2).

Nobel Laureates

A number of scientists in medicine or physiology have been awarded Nobel prizes for their contributions in microbiology (Table 1.3).

TABLE 1.1: Discovery of important microorganisms

Discoverer	Organism
Ogston	*Staphylococcus aureus*
Neisser	*Neisseria gonorrhoeae*
Weichselbaum	*Neisseria meningitidis*
Loeffler	*Corynebacterium diphtheriae*
Frenkel	*Streptococcus pneumoniae*
Bruce	*Brucella melitensis*
Kitasato	*Clostridium tetani*
Hansen	*Mycobacterium leprae*
Yersin and Kitasato	*Yersinia pestis*
Schaudinn and Hoffman	*Treponema pallidum*
Daniel Carrion	*Bartonella bacilliformis*
d'Herelle	Bacteriophages
W.H. Welch	*Clostridium perfringens*
Anthony Epstein and Yvonne Barr	Epstein-Barr virus

TABLE 1.2: Bacteria named after the discoverers

Common name	Scientific name
Kleb-Loeffler bacillus	*Corynebacterium diphtheriae*
Preisz Nocard bacillus	*Corynebacterium pseudotuberculosis*
Koch Week bacillus	*Haemophilus aegyptius*
Pfeiffer's bacillus	*Haemophilus influenzae*
Whitmore's bacillus	*Burkholderia pseudomallei*
Battey bacillus	*Mycobacterium intracellulare*
Johne's bacillus	*Mycobacterium paratuberculosis*
Eaton's agent	*Mycoplasma pneumoniae*
Gaffky-Eberth bacillus	*Salmonella* Typhi

BACTERIAL TAXONOMY

Bacterial taxonomy comprises of three separate but interrelated important areas.

1. **Classification:** It refers to hierarchy based arrangement of bacteria into taxonomic groups or taxa (singular, taxon) on the basis of similarities or differences in their biochemical, physiological, genetic, and morphological properties.
2. **Nomenclature:** It refers to the naming of taxa according to their characteristics, by following the international rules.
3. **Identification:** It refers to the practical use of a classification scheme such as: (1) Identification of an unknown taxon by comparing with a defined and named taxon, (2) To isolate and identify the causative agent of a disease.

TABLE 1.3: Nobel laureates in medicine or physiology for their contributions in microbiology

Nobel laureate	Year	Research done
Emil A von Behring	1901	Development of antitoxin against diphtheria
Sir Ronal Ross	1902	Life cycle of malarial parasite in mosquitoes
Robert Koch	1905	Discovery of the causative agent of tuberculosis
Charles LA Laveran	1907	Discovery of malarial parasite in unstained preparation of blood
Paul Ehrlich and Elie Metchnikoff	1908	Discovered selective theory of antibody formation
Charles Richet	1913	Discovered anaphylaxis
Jules Bordet	1919	Discovered complement and developed complement fixation test

BACTERIAL CLASSIFICATION

The most recent taxonomic classification of bacteria is based on Cavalier and Smith's six kingdoms classification (1998). It is the most accepted classification at present, surpassed the previous five kingdom classification (Whittaker, 1969) and three domain classification (Woese, 1990) (Table 1.4).

Cavalier and Smith's Classification

It is a molecular classification, which divides all living structures of the earth into six kingdoms—Bacteria, Protozoa, Chromista, Plantae, Fungi and Animalia.

Kingdom Bacteria is divided successively in decreasing order of hierarchy into phylum/division, class, order, suborder, family, tribe, genus and species. For example, the full taxonomical position of *Escherichia coli* is given in Table 1.5.

Principle Used to Classify Bacteria

There is no universally accepted principle to classify bacteria. There are mainly three approaches, phylogenetic, Adansonian and molecular.

TABLE 1.4: Taxonomic classification of living beings

Linnaeus 1735	Haeckel 1866	Chatton 1925	Copeland 1938	Whittaker 1969	Woese et al. 1990	Cavalier-Smith 1998
2 kingdoms	3 kingdoms	2 empires	4 kingdoms	5 kingdoms	3 domains	6 kingdoms
(not treated)	Protista	Prokaryota	Monera	Monera	Bacteria	Bacteria
					Archaea	
		Eukaryota	Protista	Protista	Eucarya	Protozoa
						Chromista
Vegetabilia	Plantae		Plantae	Plantae		Plantae
				Fungi		Fungi
Animalia	Animalia		Animalia	Animalia		Animalia

TABLE 1.5: Taxonomical position of *Escherichia coli*

Kingdom	Ends with suffix	Bacteria
Phylum		Proteobacteria
Class	-ia	Gammaproteobacteria
Subclass	-idae	
Order	-ales	Enterobacteriales
Suborder	-ineae	
Family	-aceae	Enterobacteriaceae
Subfamily	-oideae	
Tribe	-eae	Escherichieae
Subtribe	-inae	
Genus		*Escherichia*
Species		*E. coli*

Phylogenetic Classification

This is a hierarchical classification representing a branching tree-like arrangement; one characteristic (or trait) is being employed for division at each node of the tree (Fig. 1.2).

- This system is called phylogenetic because it implies an evolutionary arrangement of species.
- Here, the characteristics are arbitrarily given special weightage. Depending on the characteristic so chosen, the classification would give different patterns.
- The characteristics which are given importance depend up on various properties of the organisms such as:
  - Morphology of bacteria—cocci or bacilli.
  - Staining property such as gram-positive and gram-negative.

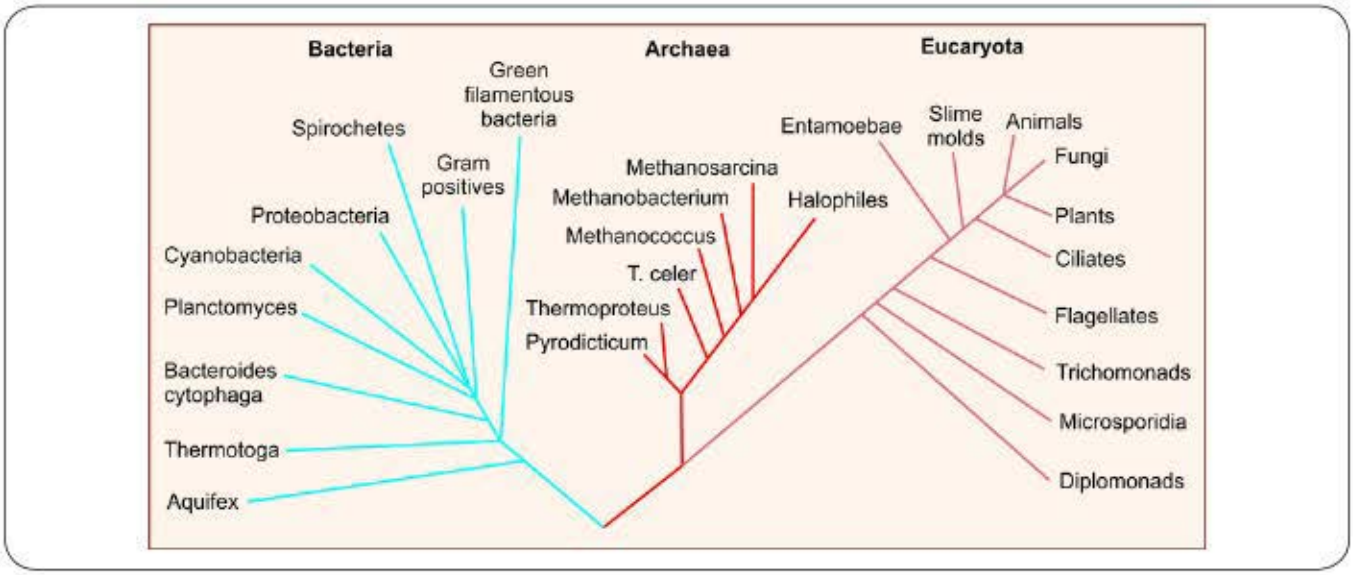

Fig. 1.2: Phylogenetic tree of classifying living structures based on weighted characters

- Cultural characteristics such as lactose fermenting and non-lactose fermenting colonies.
- Biochemical reactions, e.g. coagulase positive *Staphylococcus* and coagulase negative *Staphylococcus*.
- Antigenic structure, e.g. antigenic structure of somatic antigen present in bacterial cell wall.

- Though, this classification is a **convenient and user friendly** method, but it is not a perfect method. Because the weighted characters used may not be valid all the time for a given bacterium. For example, fermentation of lactose though is an important property to classify family Enterobacteriaceae; but is not a permanent trait. In due course of the time, bacteria may lose or gain the property to ferment lactose.

Adansonian Classification

To avoid the use of weighted characteristics, Michel Adanson proposed another method (1774) that classifies organisms based on giving equal weight to every character of the organism.

- This is also called phenetic classification. It has its greatest application in numeric taxonomy.
- Numerical taxonomy: The concept was first developed by Robert R Sokal and Peter HA Sneath in 1963.
- With the advent of computer facilities, the principle of phenetic classification has been extended further so that very large numbers of characters of several organisms can be compared at the same time.
- They have created a taxonomic system by using numeric algorithms like cluster analysis rather than using subjective evaluation of their properties which are arbitrarily given special weightage.

Molecular Classification

It is based on the degree of genetic relatedness of different organisms. Guanine + cytosine (G + C) content of bacteria is estimated after extracting DNA from pure bacterial culture. The nucleotide base composition and the base ratio vary widely among different groups of microorganisms, but for any one particular species, it is constant.

NOMENCLATURE

Nomenclature is the branch of taxonomy, that is concerned with designating scientific names to taxa, based on a particular classification scheme and in accordance with agreed international rules and conventions.

- Bacterial nomenclature also follows the same rules as proposed by Swedish botanist **Carolus Linnaeus** who invented the modern system of binomial nomenclature.
- Scientific names for taxonomic levels above genus are always capitalized but not italicized; for example, Phylum Proteobacteria.
- In binomial nomenclature system, the scientific name of bacteria comprises of a genus name (starts with a capital letter) and species name. Both genus and species should be written in *italic* or are underlined; e.g. *Staphylococcus aureus* or Staphylococcus aureus.
- The genus (plural: genera) is usually a Latin noun whereas the species refers to a defined taxon of organisms within a particular genus.
- The genus and species are coined based on some property of the bacteria; for example,
  - *Staphylococcus aureus* is named after their arrangement in cluster (*Staphyle* means as bunch of grapes) and type of pigmentation they produce (*aureus* meaning golden yellow)
  - *Neisseria meningitidis* is named after—the discoverer (U. Neisser) and the disease it causes (meningitis).
  - *Brucella suis* and *Brucella melitensis* (named after the discoverer (*Brucella* from David Bruce) and the animal host (*suis* meaning pig) and the place of discovery (*melitensis* from Malta, Europe).
- **Typing:** The species can also be classified further by various typing methods as described in Chapter 5.

Type Cultures

There are many international reference laboratories which are designated as type culture reference centers.

- They maintain the representative cultures of the established species, which show all the standard characteristics of the original strain.
- The strains isolated in the laboratories are compared using the standard strains supplied by these type culture centers.
- The original cultures of any new species described are deposited in type collection centers.
- The two most important type collection centers of the world are:
  - **ATCC** (American Type Culture Collection), USA
  - **NCTC** (National Collection of Type Cultures), UK.

EXPECTED QUESTIONS

I. Write short notes on:

1. Bacterial taxonomy
2. Contributions of Louis Pasteur in the field of microbiology
3. Contributions of Robert Koch in the field of microbiology

CHAPTER 2

Morphology and Physiology of Bacteria

Chapter Preview

- Classification of microorganisms
- Microscopy
- Staining techniques
- Morphology of bacteria
  - Bacterial cell wall
  - Cell wall appendages and other structures
- Physiology of bacteria
  - Bacterial growth and nutrition
  - Bacterial metabolism

CLASSIFICATION OF MICROORGANISMS

Microorganisms are grouped under both prokaryotes and eukaryotes.

- Bacteria and blue green algae are placed under prokaryotes. They have a primitive nucleus, and other properties of a prokaryotic cell (Table 2.1).
- Whereas other algae, fungi and parasites (protozoa and helminths) belong to eukaryotes; having a well-defined nucleus and various eukaryotic cellular organelles.
- Viruses are considered neither prokaryotes nor eukaryotes because they lack the characteristics of living things, except the ability to replicate.

Size of the microorganisms

Microorganisms are extremely small. The size of the bacteria is expressed in micrometers ($1\mu m = 10^{-3}$ mm) whereas viruses are measured in nanometers ($1nm = 10^{-3}\mu m$).

Most of the bacteria of medical importance generally measure 0.2–1.5 μm in diameter and about 3–5 μm in length, while the majority of the human pathogenic viruses range 20–300 nm in diameter.

Because of the small size, microorganisms cannot be seen distinctly with the unaided eye but need a microscope for their visualization. Most bacteria can be observed by light microscope whereas viruses need an electron microscope. Hence, it is important to understand how the microscope works and the method of specimen preparation (staining techniques) for examination.

TABLE 2.1: Characteristics of prokaryotes and eukaryotes

Characteristics	Prokaryotes	Eukaryotes
Major groups	Bacteria, blue green algae	Fungi, parasites, other algae, plants and animals
Nucleus	Diffuse	Well defined
Nuclear membrane	Absent	Present
Nucleolus	Absent	Present
Ribonucleoprotein	Absent	Present
Cell division	Binary fission	Mitosis, meiosis
Chromosome	One, circular	Many, liner
Extrachromosomal DNA	Found in plasmid	Found in mitochondria
Cell membrane	Does not contain sterols except in mycoplasma	Contain sterols
Cellular organelles like mitochondria, etc.	Absent (except ribosome)	Present
Ribosome	70S	80S
Site of respiration	Mesosome	Mitochondria
Pinocytosis	Absent	Present

MICROSCOPY

The following types of microscopes are in use now.

- Bright-field or light microscope
- Dark field microscope
- Phase contrast microscope
- Fluorescence microscope
- Electron microscope

Properties of a microscope

A good microscope should have at least three properties:

1. **Good resolution:** Resolution power refers to the ability to produce separate images of closely placed objects so that they can be distinguished as two separate entities. The resolution power of—

- Unaided human eye is about 0.2 mm (200 µm).
- Light microscope is about 0.2 µm.
- Electron microscope is about 0.5 nm.

Resolution depends on refractive index of the medium. Oil has a higher refractive index than air; hence, use of oil enhances the resolution power of a microscope.

2. **Good contrast:** This can further be improved by staining the specimen. When the stains bind to the cells, the contrast is increased.
3. **Good magnification:** This is achieved by use of lenses. There are two type of concave lenses used:
   - Ocular lens with a magnification power of 10x.
   - Objective lens-scanning (4x), low power (10x), high power (40x) and oil immersion (100x).

   Total magnification of a field is the product of the magnification of objective lens and ocular lens:
   - Scanning field (40x)
   - Low power field (100x)
   - High power field (400x) and
   - Oil immersion field (1000x)

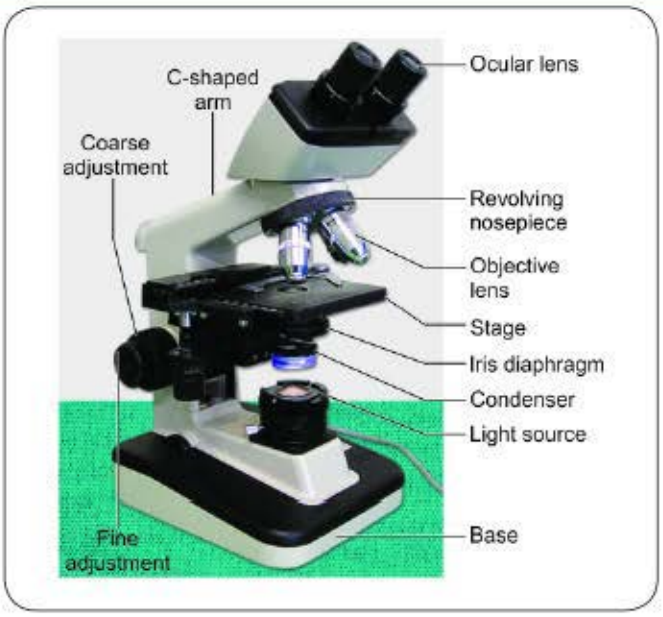

Fig. 2.1: Bright-field microscope

Source: Nikon Alphaphot

BRIGHT-FIELD OR LIGHT MICROSCOPE

The bright-field or light microscope forms a dark image against a brighter background, hence the name.

Structure

The parts in a bright-field microscope are divided into three groups (Fig. 2.1):

Mechanical Parts

- **Base:** It holds various parts of microscope, such as the light source, the fine and coarse adjustment knobs.
- **C-shaped arm:** It holds the microscope, and it connects the ocular lens to the objective lens.
- **Mechanical stage:** The arm bears a stage with stage clips to hold the slides and the stage control knobs to move the slide during viewing. It has an aperture at the center that permit light to reach the object from the bottom.

Magnifying Parts

- **Ocular lens:** The arm contains an eyepiece that bears an ocular lens of 10x magnification power. Microscopes with two eye pieces are called as binocular microscopes.
- **Objective lens:** The arm also contains a revolving nose piece that bears three to five objectives with lenses of differing magnifying power (4x,10x,40x and 100x).

Illuminating Parts

- Condenser: It is mounted beneath the stage which focuses a cone of light on the slide.
- Iris diaphragm: It controls the light that passes through the condenser.
- Light source: It may be a mirror or an electric bulb.
- Fine and coarse adjustment knobs: They sharpen the image.

Working Principle

The rays emitted from the light source pass through the iris diaphragm and fall on the specimen. The light rays passing through the specimen is gathered by the objective and a magnified image is formed. This image is further magnified by the ocular lens to produce the final magnified virtual image (Fig. 2.2).

DARK FIELD MICROSCOPE

Principle

In dark field microscope, the object appears bright against a dark background. This is made possible by use of a special dark field condenser (Fig. 2.2).

- The dark field condenser has a central opaque area that blocks light from entering the objective lens directly and has a peripheral annular hollow area which allows the light to pass through and focus on the specimen obliquely.
- Only the light which is reflected by the specimen enters the objective lens whereas the unreflected light does not enter the objective. As a result, the specimen is brightly illuminated; but the background appears dark.

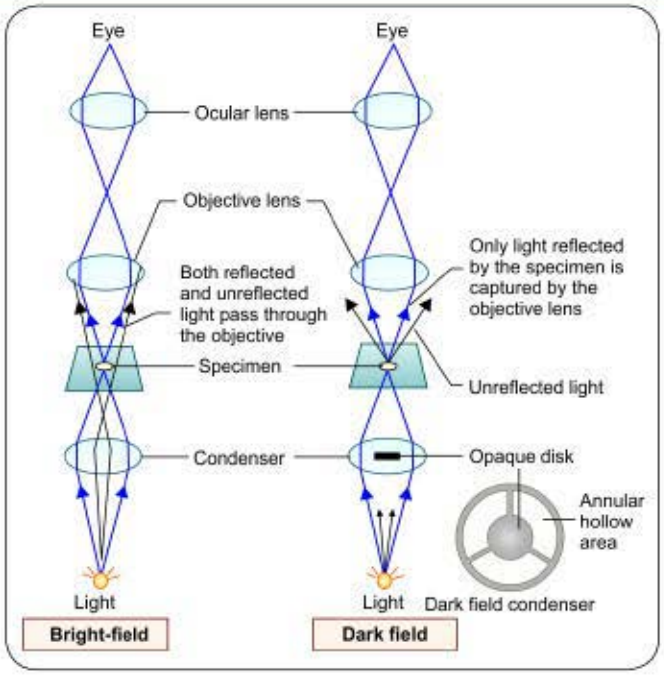

Fig. 2.2: Light pathways of bright-field and dark field microscopes

Applications

Dark field microscope is used to identify the living, unstained cells and thin bacteria like spirochetes which cannot be visualized by light microscopy.

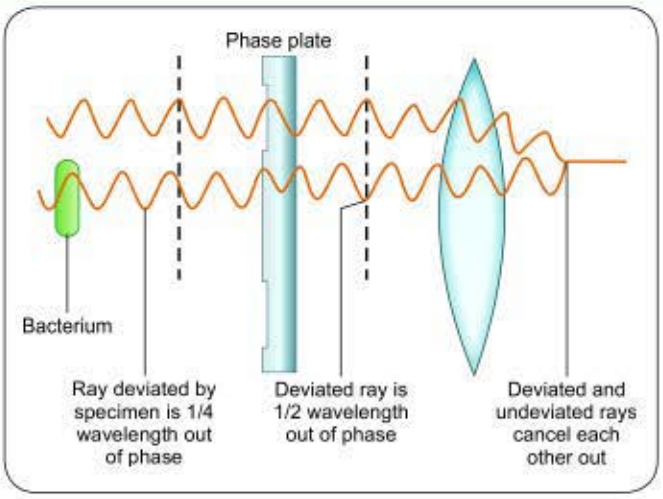
PHASE CONTRAST MICROSCOPE

As per its name, in phase contrast microscope the contrast is enhanced. This microscope visualizes the unstained living cells by creating difference in contrast between the cells and water. It converts slight differences in refractive index and cell density into easily detectable variations in light intensity. Contrast can also be enhanced by staining the specimen, but as staining kills the microbes, the properties of living cells cannot be studied.

Principle

The condenser is similar to that of dark field microscope, consists of an opaque central area with a thin transparent ring, which produces a hollow cone of light.

- As this cone of light passes through a cell, some light rays are bent due to variations in density and refractive index within the specimen and are retarded by about one-fourth of a wavelength (Fig. 2.3).
- The undeviated light rays strike a **phase ring** in the phase plate, (a special optical disk located in the objective), while the deviated rays miss the ring and pass through the rest of the plate.



Phase plate
Bacterium
Ray deviated by specimen is 1/4 wavelength out of phase
Deviated ray is 1/2 wavelength out of phase
Deviated and undeviated rays cancel each other out

Fig. 2.3: Principle of phase contrast microscope

- The phase ring is constructed in such a way that the undeviated light passing through it is advanced by one-fourth of a wavelength, the deviated and undeviated waves will be about half wavelength out of the phase and will cancel each other when they come together to form an image (Fig. 2.3).
- The background, formed by undeviated light, is bright, while the unstained object appears dark and well-defined.

The light rays go through → condenser → specimen (e.g bacteria) → phase ring → objective lens → ocular lens.

Applications

Phase contrast microscopy is especially useful for studying:

- Microbial motility
- Determining the shape of living cells, and
- Detecting bacterial components, such as endospores and inclusion bodies which become clearly visible because they have refractive indices markedly different from that of water.

FLUORESCENCE MICROSCOPE

The "fluorescence microscope" refers to any microscope that uses fluorescence property to generate an image.

Principle

When fluorescent dyes are exposed to ultraviolet rays (UV) rays, they become excited and are said to fluoresce, i.e. they convert this invisible, short wavelength rays into light of longer wavelengths (i.e. visible light) (Fig. 2.4).

- The source of light may be a mercury lamp which emits rays that pass through an excitation filter.

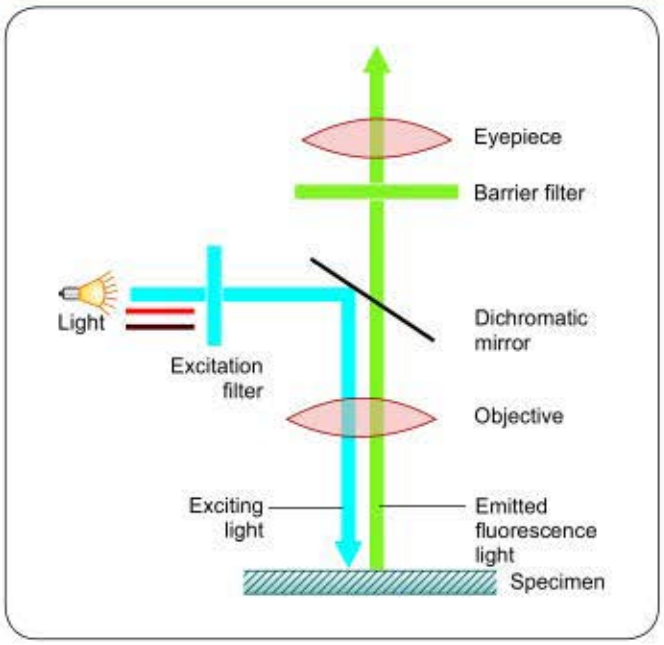


Fig. 2.4: Principle of fluorescence microscope

- The excitation filter is so designed that it allows only short wavelength UV light (about 400 nm, called as the exciting wavelength of light) to pass through; blocking all other long wavelength rays.
- The exciting rays then get reflected by a dichromatic mirror in such a way that they fall on the specimen which is priorly stained by fluorescent dye. Then the specimen is focused under the microscope.
- The fluorescent dye absorbs the exciting rays of short wavelength, gets activated and in turn emits fluorescent rays of higher wavelength.
- A barrier filter positioned after the objective lenses removes any remaining ultraviolet light, which could damage the viewer's eyes, or blue and violet light, which would reduce the image's contrast.

Applications

Epifluorescence microscope: It is the simplest format of fluorescence microscope, which has the following applications.

- **Auto fluorescence:** Certain microbes directly fluoresce when placed under UV lamp, e.g. *Cyclospora* (a protozoan parasite).
- **Microbes coated with fluorescent dye:** Certain microbes fluoresce when they are stained non-specifically by fluorochrome dyes.
  - Acridine orange dye is used for the detection of malaria parasites by a method called as quantitative buffy coat (QBC) examination.

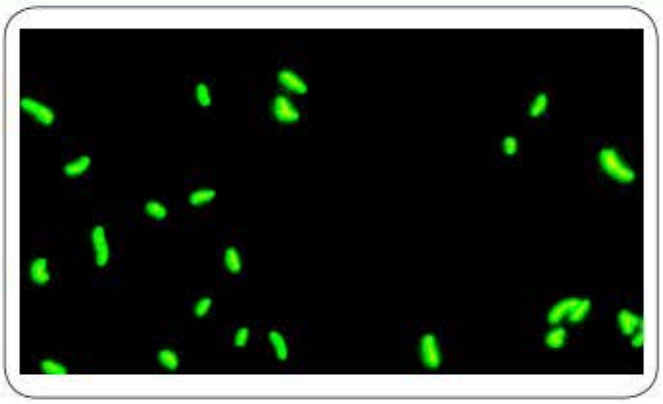

Fig. 2.5: Tubercle bacilli seen under fluorescence microscope

  - Auramine phenol is used for the detection of tubercle bacilli (Fig. 2.5).
- **Immunofluorescence:** It uses florescent dye tagged immunoglobulins to detect cell surface antigens or antibodies bound to cell surface antigens. There are two types- direct and indirect immunofluorescence test (described in detail in Chapter 12).

Confocal microscope: It is an advanced design of fluorescence microscope, which uses optical sectioning to get better resolution of the fluorescent image.

ELECTRON MICROSCOPE

An electron microscope (EM) uses accelerated electrons as a source of illumination. Because the wavelength of electrons can be up to 100,000 times shorter than that of visible light photons, the EM has a much better resolving power than a light microscope; hence, it can reveal the details of flagella, fimbriae and intracellular structures of a cell. It was invented by German physicist **Ernst Ruska** in 1931. Differences between light microscope and EM are listed in Table 2.2. Electron microscopes are of two types:

1. Transmission electron microscope (most common type) (Fig. 2.6)
2. Scanning electron microscope

TABLE 2.2: Differences between light microscope and electron microscope

Features	Light microscope	Electron microscope
Highest practical magnification	About 1,000–1,500	Over 100,000
Best resolution	0.2 µm	0.5 nm
Radiation source	Visible light	Electron beam
Medium of travel	Air	High vacuum
Specimen mount	Glass slide	Metal grid (usually copper)
Type of lens	Glass	Electromagnet

Fig. 2.6: Transmission electron microscope (parts)

Source: David J Morgan/Wikipedia

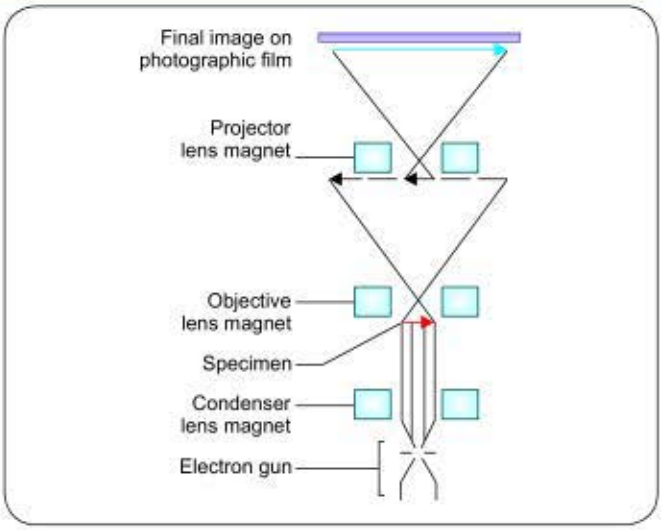

Fig. 2.7: Principle of transmission electron microscope

Transmission Electron Microscope

Specimen Preparation

The specimen to be viewed under EM should be able to maintain its structure when it is bombarded with electrons. Hence, only very thin specimens (20–100 nm thickness) are suitable for EM. However, bacterial cells are thicker than this; hence, they need to be sliced into thin layers. To prepare the thin specimen, the following steps are needed:

- **Fixation:** Cells are fixed by using glutaraldehyde or osmium tetroxide for stabilization.
- **Dehydration:** Specimen is then dehydrated with organic solvents (e.g. acetone or ethanol).
- **Embedding:** Specimen is embedded in plastic polymer and then, is hardened to form a solid block. Most plastic polymers are water insoluble; hence, complete dehydration of specimen is must before embedding.
- **Slicing:** Specimen is then cut into thin slices by an ultramicrotome knife. Such thin slices of specimen are mounted on a metal slide (copper).

Electron Pathway

Electrons are generated by electron gun, which travel in high speed. The medium of travel in EM should be a fully vacuum path because in air path, electrons can get deflected by collisions with air molecules.

- Electron pass through a magnetic condenser and then bombard on the thin sliced specimen mounted on the copper slide.
- The specimen scatters electrons passing through it, and then the electron beam is focused by magnetic lenses (objective lens followed by projector lenses) to form an enlarged, visible image of the specimen on a fluorescent screen (Fig. 2.7).
- A denser region in the specimen scatters more electrons and therefore appears darker in the image since fewer electrons strike that area of the screen. In contrast, electron-transparent regions are brighter.

Measures to Increase the Contrast of EM

- **Staining:** Like light microscopy, in EM also, the specimens can be stained. Here, the stains used are solutions of heavy metal salts like lead citrate and uranyl acetate which bind to the cell structures and make them more electron opaque, thus increasing the contrast in the material.
- **Negative staining:** The specimen is spread out in a thin film with heavy metals like phosphotungstic acid or uranyl acetate.
  - Heavy metals do not penetrate the specimen but render the background dark, whereas the specimen appears bright in photographs.
  - Negative staining is an excellent method to study the structure of viruses, bacterial gas vacuoles, and other similar material.
- **Shadowing:** Specimen is coated with a thin film of platinum or other heavy metal at 45° angle so that the metal strikes the microorganism on only one side.
  - The area coated with metal scatters electrons and appears light in photographs, whereas the uncoated side and the shadow region created by the object appears dark.
  - This technique is particularly useful in studying virus morphology, bacterial flagella, and plasmids.

Freeze-etching Technique

It is an alternate method for specimen preparation to disclose the shape of organelles within the microorganisms.

- Cells are rapidly frozen in liquid nitrogen and then warmed to –100°C in a vacuum chamber. This makes the cells weaker so that the cells can be fractured by a knife exposing the internal organelles. The knife should be precooled with liquid nitrogen (–196°C).
- **Sublimation:** The specimen is left in high vacuum for a minute or more so that some of the ice can sublimate away and uncover more structural details.
- Finally, the exposed surfaces are shadowed and coated with layers of **platinum and carbon** to form a replica of the surface.
- After the specimen has been removed chemically, this replica is studied in the TEM, which provides a detailed, **three-dimensional** view of intracellular structure.
- In freeze-etching, the danger of artefacts is minimal as the cells are frozen quickly rather than subjected to chemical fixation as done in conventional specimen preparation.

Scanning Electron Microscope (SEM)

Scanning electron microscope has been used to examine the surfaces of microorganisms in great detail. It has a resolution of 7 nm or less. The SEM differs from TEM, in producing an image from electrons emitted by an object's surface rather than from transmitted electrons.

STAINING TECHNIQUES

Structural details of bacteria cannot be seen under light microscope due to lack of contrast. Hence, it is necessary to use staining methods to produce color contrast and thereby increase the visibility. Before staining, the fixation of the smear to the slide is done.

Fixation

Fixation is the process by which the internal and external structures of cells are preserved and fixed in position. It also inactivates the enzymes that might disrupt cell morphology. It toughens cell structure so that they do not change during staining. It kills and fixes the cells on to the slide.

There are two types of fixation as follows:

- **Heat fixation:** It is usually done for **bacterial smears** by gently flame heating an air-dried film of bacteria. This adequately preserves overall morphology but not structures within the cells.
- **Chemical fixation:** It can be done using ethanol, acetic acid, mercuric chloride, formaldehyde, methanol and glutaraldehyde. They are used to protect the fine internal structure of cells. This is useful for examination of **blood smears**.

The fixed smear is stained by appropriate staining technique.

COMMON STAINING TECHNIQUES USED IN MICROBIOLOGY

- **Simple stain:** Basic dyes, such as methylene blue or basic fuchsin are used as simple stains. They provide the color contrast, but impart the same color to all the bacteria in a smear.
- **Negative staining:** A drop of bacterial suspension is mixed with dyes, such as India ink or nigrosin. The background gets stained black where as unstained bacterial/yeast capsule stand out in contrast. This is very useful in the demonstration of bacterial/yeast capsules which do not take up simple stains.
- **Impregnation methods:** Bacterial cells and structures that are too thin to be seen under the light microscope, are thickened by impregnation of silver salts on their surface to make them visible, e.g. for demonstration of bacterial flagella and spirochetes.
- **Differential stain:** Here, two stains are used which impart different colors to different bacteria or bacterial structures, which help in differentiating bacteria. The most commonly employed differential stains are—
  - **Gram stain:** It differentiates bacteria into gram-positive and gram-negative groups
  - **Acid-fast stain:** It differentiates bacteria into acid-fast and non acid-fast groups
  - **Albert stain:** It differentiates bacteria having metachromatic granules from other bacteria that do not have.

GRAM STAIN

This staining technique was originally developed by Hans Christian Gram (1884). Even after more than 130 years of its discovery and even if the newer modern diagnostic facilities are available, still Gram stain remains the most widely used stain in diagnostic bacteriology.

Procedure

- **Fixation:** The smear made on a slide from bacterial culture or specimen, is air dried and then heat fixed.
- **Primary stain:** The smear is stained with pararosaniline dyes such as crystal violet (or gentian violet or methyl violet) for one minute. Then the slide is rinsed with water. Crystal violet stains all the bacteria violet in color (irrespective of whether they are gram-positive or negative).
- **Mordant:** Gram's iodine (dilute solution of iodine) is poured over the slide for one minute. Then the slide is rinsed with water. Gram's iodine acts as a mordant.

- **Decolorization:** Next step is pouring of few drops of decolorizer to the smear: e.g. acetone (for 1–2 sec) or ethanol (20–30 sec) or acetone alcohol (for 10 sec) or iodine acetone. Slide is immediately rinsed with water. Decolorizer removes the primary stain from gram-negative bacteria while the gram-positive bacteria retain the primary stain.

> **Note: Decolorization** is the most crucial step of Gram stain. If the decolorizer is poured for more time, even gram-positive bacteria loose color **(over decolorization)** and if poured for less time, the gram-negative bacteria do not lose the color of primary stain properly **(under decolorization)**.

- **Counter stain:** Secondary stains such as safranin or diluted carbol fuchsin is added for 30 seconds. It imparts pink or red color to the gram-negative bacteria. Alternatively, neutral red may also be used as counter stain, especially for gonococci. The slide is rinsed in tap water, dried, and then examined under oil immersion objective.

The steps of Gram staining and the color of gram-positive and negative bacteria after each step are depicted in Figure. 2.8.

Interpretation of Gram Stain

Smear is examined under oil immersion objective.

- Gram-positive resist decolorization and retain the color of primary stain i.e. violet.
- Gram-negative bacteria are decolorized and, therefore, take counterstain and appear pink.

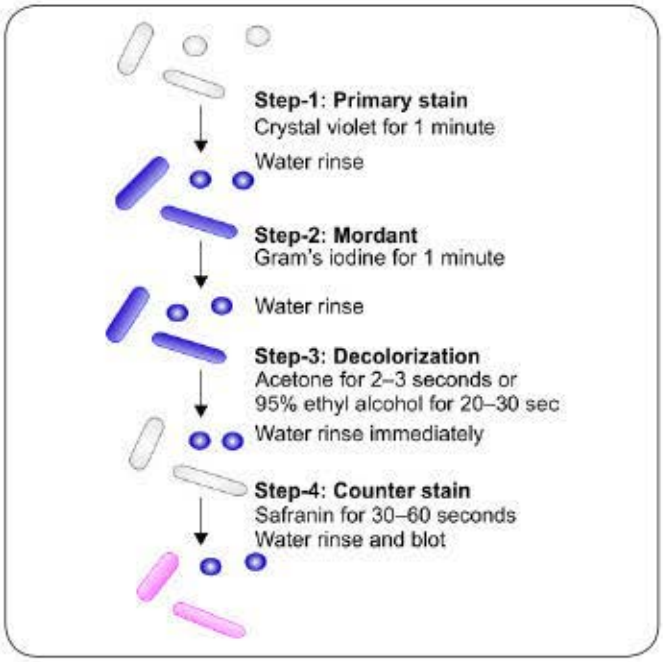

Fig. 2.8: Principle and procedure of Gram staining

Principle of Gram Staining

Though the exact mechanism is not understood, the following theories have been put forward.

- **pH theory:** Cytoplasm of gram-positive bacteria is more acidic, hence, can retain the basic dye (e.g. crystal violet) for longer time. **Iodine** serves as mordant, i.e. it combines with the primary stain to form a dye-iodine complex which gets retained inside the cell.
- **Cell wall theory:** This is believed to be the most important postulate to describe the mechanism of Gram stain.
  - Gram-positive cell wall has a thick peptidoglycan layer (50–100 layers thick), which are tightly cross linked to each other.
  - The peptidoglycan itself is not stained; instead, it seems to act as a permeability barrier preventing loss of crystal violet. More so, alcohol is thought to shrink the pores of the thick peptidoglycan.
  - Gram-negative cell wall is more permeable thus allowing the out flow of crystal violet easily. This is attributed to—
    - The thin peptidoglycan layer in gram-negative cell wall which is not tightly cross linked.
    - Presence of lipopolysaccharide layer in the cell wall of gram-negative bacteria, which gets disrupted easily by the action of acetone or alcohol; thus allowing the primary stain to come out of the cytoplasm.
    - After mordanting with Gram's iodine, bigger dye-iodine complexes are formed in the cytoplasm. Following decolorization, as more lipid content in gram-negative bacterial cell wall gets dissolved leading to formation of larger pores through which the dye-iodine complexes escape. Due to less lipid in gram-positive bacterial cell wall smaller pores are formed which do not allow the dye-iodine complexes to escape.

Modifications of Gram Staining

There are few minor modifications of Gram stain which vary slightly from the method described earlier.

- **Kopeloff and Beerman's modification:** Primary stain and counter stain used are methyl violet and basic fuchsin respectively.
- **Jensen's modification:** This method involves use of absolute alcohol as decolorizer and neutral red as counter stain. It is useful for meningococci and gonococci.

- **Weigert's modification:** This modification is useful for staining tissue sections. Here, aniline-xylol is used as a decolorizer.
- **Preston and Morrell's modification:** Here, iodine-acetone is used as decolorizer.

Uses of Gram Stain

- **Differentiation of bacteria into gram-positive and gram-negative:** It is the first step towards identification of bacteria.
- **For identification:** Gram staining from bacterial culture gives an idea to put the corresponding biochemical test for further identification of bacteria
- **To start empirical treatment:** Gram stain from specimen gives a preliminary clue about the bacteria present (based on the shape and Gram staining property of the bacteria) so that the empirical treatment with broad spectrum antibiotics can be started early before the culture report is available.
- **For fastidious organisms**, such as *Haemophilus* which takes time to grow in culture; Gram stain helps in early presumptive identification.
- **Anaerobic organisms**, such as *Clostridium*, which do not grow in routine culture. Hence, Gram stain gives a preliminary clue to put anaerobic culture.
- **Yeasts:** In addition to stain the bacteria, Gram stain is useful for staining certain fungi such as *Candida* and *Cryptococcus* (appear gram-positive).

ACID-FAST STAIN

The acid-fast stain was discovered by Paul Ehrlich and subsequently modified by Ziehl and Neelsen. This staining is done to identify acid-fast organisms, such as *Mycobacterium tuberculosis* and others (Table 2.3). Acid-fastness is due to presence of mycolic acid in the cell wall.

TABLE 2.3: Acid-fast organisms/structures and percentage of sulfuric acid suitable for staining

Acid-fast organisms /structures	Sulfuric acid (%) needed for decolorization
Mycobacterium tuberculosis	25%
Mycobacterium leprae	5%
Nocardia	1%
Acid-fast parasites such as *Cryptosporidium*, *Cyclospora*, *Isosopra*, Microsporidia, Taenia saginata (segments and eggs), hooklets of hydatid cyst and eggs of *Schistosoma mansoni*	1%
Bacterial spore	0.25–0.5%
Sperm head	0.5–1%
Legionella micdadei	0.5–1%

Ziehl-Neelsen Technique (Hot Method)

- **Fixation:** The smear is heat fixed.
- **Primary stain:** Smear is poured with strong carbol fuchsin for 5 minutes with intermittent heating by flaming the underneath of the slide until the fumes appear (refer Chapter 27 for detail).
- **Decolorization:** It is done by adding 25% sulfuric acid for 3 minutes.
- **Counter staining:** It is done by adding methylene blue for 1 minute. Slide is rinsed in tap water, dried, and t hen examined under oil immersion objective.

Interpretation

Mycobacterium tuberculosis appears as long slender, beaded, red colored acid-fast bacillus. Other non-acid fast organisms present in the smear and the background take up the counter stain and appear blue (refer Fig. No. 27.2 of Chapter 27).

Modifications of Acid-Fast Staining

Hot method (Ziehl–Neelsen technique) is the most commonly done acid-fast staining technique. Other modifications are as follows:

- **Cold method (Kinyoun's method):** It is modification, where the intermittent heating is not required. (Described in detail in Chapter 27).
- Acid-alcohol can be used as decolorizer alternatively.
- Malachite green can be used as counter stain.
- Concentration of sulphuric acid may vary depending on the acid-fastness of the structure to be demonstrated. More the content of mycolic acid in the cell wall, more is the acid-fastness, hence more is the percentage of sulphuric acid needed for decolorization (Table 2.3).

ALBERT STAIN

Albert stain is used to demonstrate the metachromatic granules of *Corynebacterium diphtheriae*.

Procedure

- Fixation: The smear is heat fixed.
- Smear is covered with Albert I (Albert's stain) for 5 minutes, then is washed in water, and blotted dry.
- Albert II (iodine solution) is added for 1 minute.
- Slide is washed in water, blotted dry and examined under oil immersion field.

Interpretation

C. diphtheriae appears as green colored bacilli arranged in Chinese letter or cuneiform pattern, with bluish black metachromatic granules at polar ends. (Refer Fig. no. 24.2 of Chapter 24). These can be differentiated from diphtheroids which do not show granules and are arranged in palisade pattern. However, certain bacteria,

such as *C. xerosis* and *Gardnerella vaginalis* also possess metachromatic granules.

MICROSCOPY OF BACTERIA IN LIVING STATE

Unstained (Wet) Preparations

Unstained preparations are examined mainly for checking bacterial motility (e.g. hanging drop and wet mount preparations) and for demonstration of spirochetes (e.g. dark field or phase contrast microscopy).

Vital Stains

Vital stains are capable of differentiating the living cells from dead cells. The live cells are capable of excluding the dye and stain negatively whereas the dead cells stain positively as they cannot exlude the dye. The viability can be assessed by counting the percentage of total cells that stain negatively. Vital stains have greater applications in some diagnostic and surgical techniques.

- In **supravital staining**, living cells that have been removed from an organism are stained (in vitro), whereas the **intravital staining** is done by injecting stain into the body (in vivo).
- Examples of vital stains are eosin, propidium iodide, trypan blue, erythrosine and neutral red.

MORPHOLOGY OF BACTERIA

SHAPE OF BACTERIA

Depending on their shape, bacteria are classified into:

- Cocci (singular coccus, from; kokkos, meaning berry)-are oval or spherical cells and
- Bacilli or rods (singular bacillus, meaning rod shaped).

Cocci are arranged in groups (clusters), pair or chains. Similarly, bacilli can be arranged in chain, pair, and some bacilli are curved, comma shaped, or cuneiform shaped (Table 2.4, Fig. 2.9).

Both cocci and bacilli are further classified based on Gram staining property into (Table 2.4, Fig. 2.9):

- Gram-positive cocci
- Gram-negative cocci
- Gram-positive bacilli
- Gram-negative bacilli

However, there are some bacteria that are weakly Gram stained and hence need special stains for their demonstration, such as:

- Spirochetes (*Treponema* and *Leptospira)*—thin spirally coiled bacilli.
- Mycoplasm as (cell wall deficient free living bacteria)
- Rickettsiae and chlamydiae are obligate intracellular bacteria.

TABLE 2.4: Classification of bacteria depending on their morphology and Gram staining property

Bacteria	Example
Gram-positive cocci arranged in	
Cluster	*Staphylococcus*
Chain	*Streptococcus*
Pairs, lanceolate shaped	Pneumococcus
Pair or in short chain, spectacle eyed shape	*Enterococcus*
Tetrads	*Micrococcus*
Octate	*Sarcina*
Gram-negative cocci arranged in	
Pairs, lens shaped	Meningococcus
Pairs, kidney shaped	Gonococcus
Gram-positive bacilli arranged in	
Chain (bamboo stick appearance)	*Bacillus anthracis*
Chain	*Streptobacillus*
Chinese letter or cuneiform pattern	*Corynebacterium diphtheriae*
Palisade pattern	Diphtheroids
Branched and filamentous form	*Actinomyces* and *Nocardia*
Gram-negative bacilli arranged in	
Pleomorphic (various shapes)	*Haemophilus, Proteus*
Thumb print appearance	*Bordetella pertussis*
Comma shaped (fish in stream appearance)	*Vibrio cholerae*
Curved	*Campylobacter* (Gull-wing shaped) and *Helicobacter*
Spirally coiled, flexible	Spirochetes
Rigid spiral forms	*Spirillum*
Bacteria that lack cell wall	*Mycoplasma*

Bacterial cell anatomy comprises of the following structures (Fig. 2.10):

- The outer layer or the **envelope** of a bacterial cell consists of—(1) a rigid cell wall and (2) underlying plasma membrane.
- The cytoplasm contains cytoplasmic inclusions (mesosomes, ribosomes, inclusion granules, vacuoles) and a diffuse nucleoid containing single circular chromosome.
- Some bacteria may possess additional cell wall appendages such as capsule, flagella and fimbriae.

BACTERIAL CELL WALL

The cell wall is a tough and rigid structure, surrounding the bacterium. It is 10–25 nm in thickness and weighs about 20–25% of the dry weight of the cell.

The cell wall has following functions:

- It provides protection to the cell against osmotic lysis.
- It confers rigidity upon bacteria due to presence of peptidoglycan layer in the cell wall.

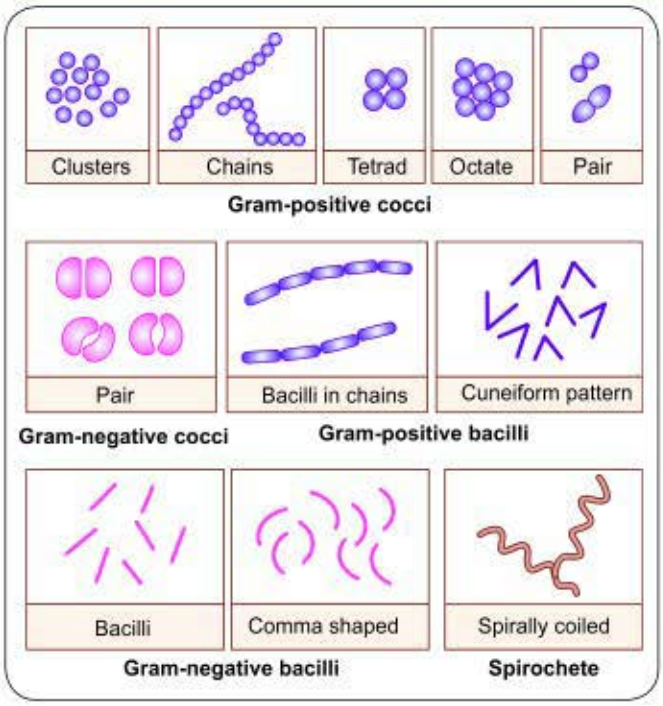

Fig. 2.9: Different morphology of bacteria and Gram-staining property

- It accounts for the shape of the cell.
- It takes part in cell division.
- The cell wall can protect a cell from toxic substances and isthe site of action of several antibiotics.
- Virulence factors-Bacterial cell wall contains certain virulence factors (e.g. endotoxin), which contribute to their pathogenicity.
- Immunity: Antibody raised against specific cell wall antigens (e.g. antibody to LPS) may provide immunity against some bacterial infection.

Gram-positive Cell Wall

Cell wall of gram-positive bacteria is simpler than that of gram-negative bacteria (Table 2.5).

Peptidoglycan

In gram-positive bacteria, the peptidoglycan layer is much thicker (50–100 layers thick, 16–80 nm) than gram-negative cell wall (Fig. 2.11).

- Each layer is a mucopeptide (murein) chain, composed of alternate units of N-acetyl muramic acid (NAM) and N-acetyl glucosamine (NAG) molecules; cross linked to each other via tetrapeptide side chains and pentaglycine bridges.
- A tetrapeptide side chain ascended from NAM molecule is composed of L-alanine—D-glutamine—L-lysine—D-alanine.

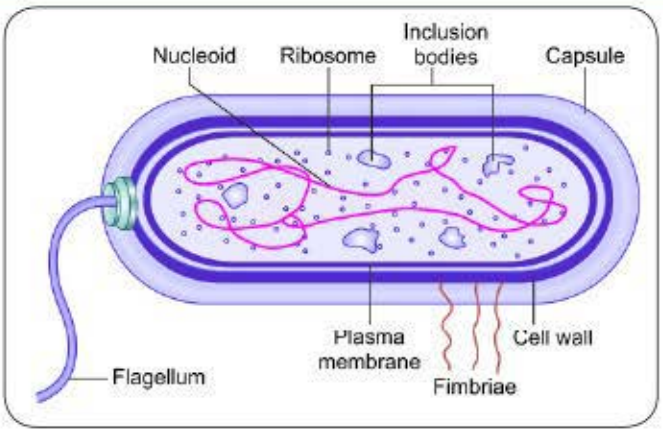

Fig. 2.10: Structure of bacterial cell

TABLE 2.5: Differences between gram-positive and gram-negative cell wall

Characters	Gram-positive cell wall	Gram-negative cell wall
Peptidoglycan layer	Thicker (15–80 nm)	Thinner (2 nm)
At third position of tetrapeptide side chain	L-Lysine present	Mesodiaminopimelic acid present
Pentaglycine bridge	Present	Absent
Lipid content	Nil or scanty (2–5%)	Present (15–20%)
Lipopolysaccharide	Absent	Present **(endotoxin)**
Teichoic acid	Present	Absent
Variety of amino acids	Few	Several
Aromatic amino acids	Absent	Present

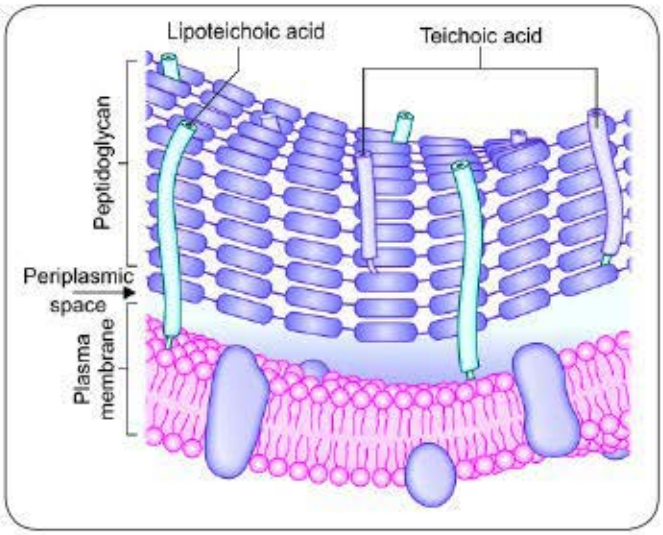

Fig. 2.11: Structure of gram-positive cell wall

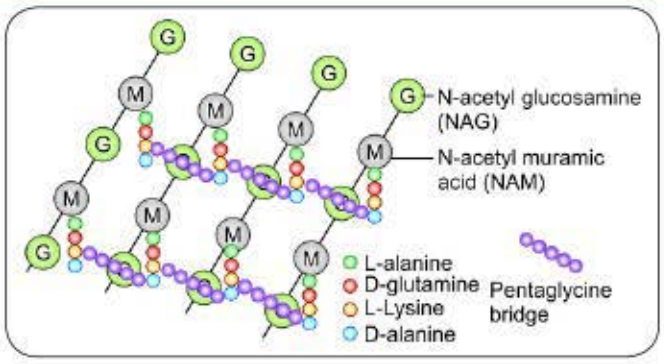

Fig. 2.12: Peptidoglycan layer of gram-positive cell wall

- The L-lysine of one tetrapeptide chain is covalently linked to the terminal D-alanine of the adjacent chain via a pentaglycine bridge. (Fig. 2.12).

Teichoic Acid

Gram-positive cell wall contains significant amount of teichoic acid which is absent in gram-negative bacteria. They are polymers of glycerol or ribitol joined by phosphate groups. The functions of these molecules are still unclear, but they may be important in maintaining the structure of the cell wall. Teichoic acids are of two types:

1. Cell wall teichoic acid: It is covalently linked to NAM molecules of peptidoglycan.
2. Lipoteichoic acid: It is attached to lipid groups of cell membrane.

Gram-negative Cell Wall

Gram-negative cell wall is thinner and more complex than the Gram-positive cell wall, comprises of the following components (Fig. 2.13) (Table 2.5).

Peptidoglycan Layer

It is very thin (1–2 layer, 2nm thick), composed of a mucopeptide chain similar to that of gram-positive cell wall, and consists of alternate NAM and NAG molecules. However, it differs from the latter by (Fig. 2.14)—

- Meso-diaminopimelic acid is present at third position of the tetrapeptide side chain ascended form NAM molecule (side chain is composed of L-alanine— D-glutamine-D—mesodiaminopimelic acid —D-alanine)
- The pentaglycine bridge is absent.
- The tetrapeptide side chains are directly linked to each other by the covalent linkage between D-alanine of one chain with mesodiaminopimelic acid of the adjacent chain.

Outer Membrane

This is a phospholipid layer which lies outside to the thin peptidoglycan layer; firmly attached to the latter by covalent linkage of membrane protein called Braun's lipoprotein.

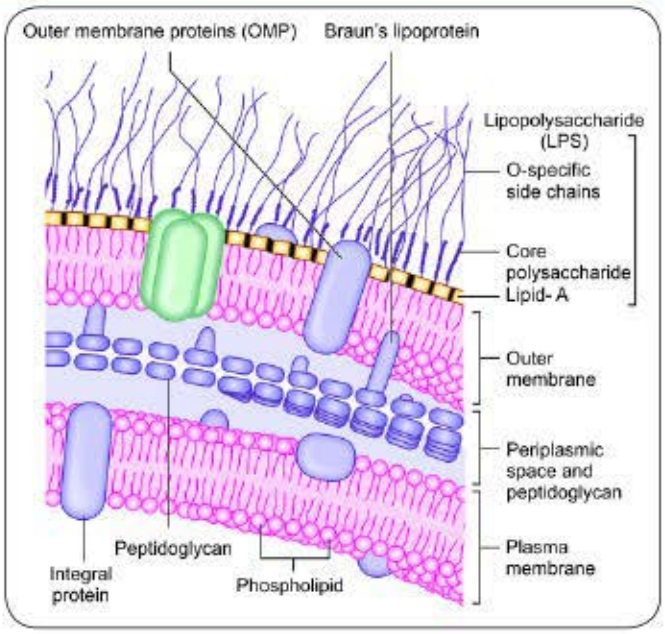

Fig. 2.13: Gram-negative cell wall

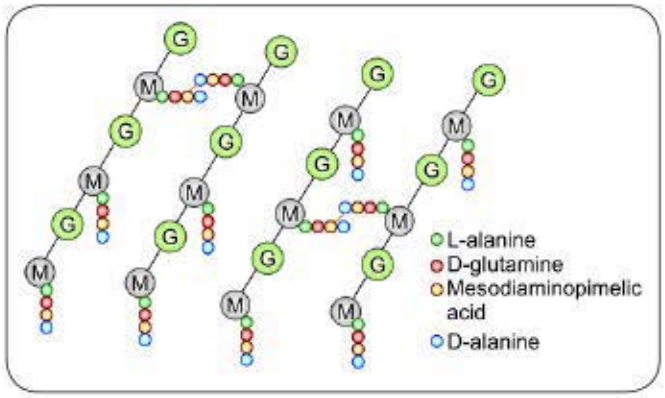

Fig. 2.14: Peptidoglycan layer of gram-negative cell wall

- It serves as a protective barrier to the cell.
- Outer membrane proteins (OMP) or porin proteins. They are the specialized proteins present in outer membrane. Three porin molecules cluster together and span the outer membrane to form a narrow channel through which molecules smaller than about 600–700 daltons can pass.
- Larger molecules such as vitamin B must be transported across the outer membrane by specific carriers.
- The outer membrane also prevents the loss of constituents such as periplasmic enzymes.

Lipopolysaccharide (LPS)

This layer is unique to gram-negative bacteria which is absent in gram-positives. It consists of three parts:

- **Lipid A or the endotoxin:** It has endotoxic activities, such as pyrogenicity, lethal effect, tissue necrosis, anti-complementary activity, B cell mitogenicity, adjuvant property and antitumour activity.
  - It consists of two glucosamine sugar derivatives, each with three fatty acids and phosphate attached.
  - It is buried in the outer membrane and the remainder of the LPS molecule projects from the surface.
- **Core polysaccharide:** It is projected from lipid A region. It is composed of 10–12 sugar moieties.
- **O side chain (or O antigen):** It is a polysaccharide chain extending outwards from the core polysaccharide region. It is made up of several sugar moieties and it greatly varies in composition between bacterial strains. O antigen is a major surface antigen (called somatic antigen), induces antibody formation. It is also used for serotyping.

Periplasmic Space

It is the space between the inner cell membrane and outer membrane. It encompasses the peptidoglycan layer.

Demonstration of the Cell Wall

The cell wall cannot be seen by light microscope and does not stain with simple dyes. Demonstration of cell wall can be done by methods such as:

- Plasmolysis: When bacteria are placed in a hypertonic saline, shrinkage of the cytoplasm occurs, while cell wall retains original shape and size.
- Microdissection
- Differential staining
- Reaction with specific antibody
- Electron microscopy

CELL MEMBRANE

The plasma membrane is essential for the survival of the bacteria.

- **Fluid mosaic model** is the most widely accepted current model to describe the membrane structure.
- It is 5–10 nm thick, composed of bilayered phospholipid in which several proteins are embedded, such as integral proteins and peripheral proteins (Fig. 2.15).
- It differs from eukaryotic membranes in **lacking sterols**, such as cholesterol (except in *Mycoplasma*). However, many bacterial membranes do contain pentacyclic sterol-like molecules called **hopanoids.**
- **Carbohydrate:** Some carbohydrates are often attached to the outer surface of plasma membrane proteins.

Functions

- It is a **semi permeable membrane** acting as an osmotic barrier; allows selectively only particular ions and molecules to pass, either into or out of the cell, while preventing the movement of others.
- **Transport system:** Proteins and enzymes present in cell membrane are involved in nutrient uptake, and waste excretion.
- **Site for metabolic processes:** Bacterial cell membrane is the site of a variety of crucial metabolic processes such as: Respiration, the synthesis of lipids and cell wall, and probably chromosome segregation.
- Special receptor molecules located in the membrane help the bacteria to detect and respond to chemicals in their surroundings.

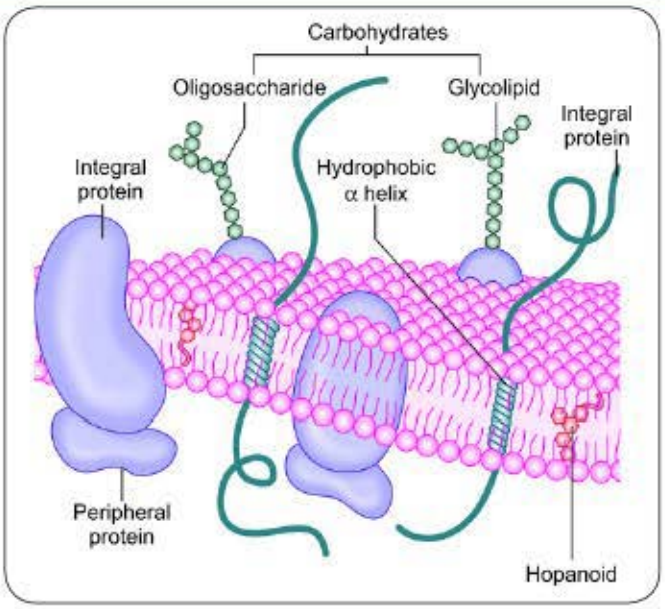

Fig. 2.15: Structure of bacterial cell membrane

CYTOPLASMIC MATRIX

Bacterial cytoplasm, unlike that of eukaryotes, lacks membrane-bound organelles. The cytoplasmic matrix is mainly composed of water (about 70% of bacterial mass is water) and is packed with ribosomes, storage granules called **inclusions** and cell membrane invaginations called **mesosomes**. They lack true cytoskeleton, but do have a cytoskeleton-like system of proteins. The plasma membrane and everything within it is called the **protoplast**.

Ribosomes

Ribosomes are the sites for protein synthesis. These are composed of rRNA and ribosomal proteins.

- Ribosomes are integrated with the mRNA to form the polysomes.
- At this site, the genetic codons of the mRNA are translated into peptide sequences.

- They are 10–20 nm size, with a sedimentation constant of 70 S (S for Svedberg units).
- Each 70 S unit consists of a 30 S and a 50 S subunits.

Intracytoplasmic Inclusions

They are the storage sites of nutrients/energy present in some bacteria. They are formed by the bacteria under nutritional deficiency conditions and disappear when the deficient nutrients are supplied. There are two types of inclusions:

- **Organic inclusion bodies**: Examples include glycogen granules and polyhydroxyl butyrate granules.
- **Inorganic inclusion bodies:** Examples include
  - Polymetaphosphate or volutin or metachromatic granules: They are found in certain bacteria, such as *Corynebacterium diphtheriae.*
  - Sulfur granules: They are found in *Actinomyces*.

Mesosomes

Mesosomes are invaginations of the plasma membrane in the shape of vesicles, tubules, or lamellae. They are generally more prominent in gram-positive bacteria.

- **Location:** Mesosomes often are found next to septa in dividing bacteria or sometimes seen attached to the bacterial chromosome.
- **Function:** They are believed to be involved in—
  - Site of bacterial respiration: They possess respiratory enzyme and are analogous to mitochondria of eukaryotes.
  - They may be involved in cell wall formation during division.
  - They also probably play a role in chromosome replication and distribution to daughter cells.

Nucleoid

Bacteria do not have a true nucleus, but the genetic material is located in an irregularly shaped region called the nucleoid. There is no nuclear membrane or nucleolus.

- Bacteria possess a single haploid chromosome, comprising of super coiled circular double stranded DNA of 1 mm length. The bacterial DNA lacks basic proteins.
- However, some bacteria have a linear chromosome and some have two chromosomes (e.g. *Vibrio cholerae*).
- Bacterial DNA divides by simple binary fission (described later in this Chapter).
- The nucleoid can be seen by electron microscopy or on staining with special stain such as the Feulgen stain.
- Bacteria also possess extrachromosomal DNA called **plasmids** (described in detail in Chapter 6).

CELL WALL APPENDAGES

Capsule and Slime Layer

Some bacteria possess a layer of amorphous viscid material lying outside the cell wall called **glycocalyx**.

- When the glycocalyx layer is well organized and not easily washed off, it is called **capsule** (Fig. 2.16).
- When the glycocalyx layer is in the form of diffuse, unorganized loose material that can be removed easily, it is called **slime layer** (Fig. 2.16).
  (Some bacteria may possess both capsule and slime layer, as in *Streptococcus salivarius)*

Examples

Most of the bacterial capsules are polysaccharide in nature (Table 2.6), except in *Bacillus anthracis* where it is polypeptide in nature. Capsule is also seen in fungi, e.g. *Cryptococcus neoformans.*

Function/Uses

The capsule has various functions as follows:

- **Contribute to bacterial virulence**:
  - Capsule protects the bacterium from phagocytosis.
  - It can also prevent complement-mediated bacterial cell lysis.

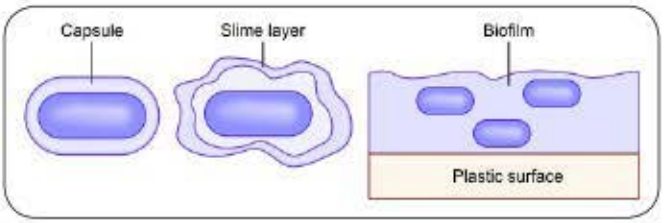

Fig. 2.16: Capsule, slime layer and biofilm

TABLE 2.6: Capsulated bacteria

Capsulated bacteria	Composition
Pneumococcus	Polysaccharide
Meningococcus	Polysaccharide
Haemophilus influenzae	Polysaccharide
Klebsiella pneumoniae	Polysaccharide
Pseudomonas aeruginosa	Polysaccharide
Bacteriodes fragilis	Polysaccharide
Bacillus anthracis	Polypeptide (glutamate)
Streptococcus pyogenes (some stains)	Hyaluronic acid
Capsulated fungus	
Cryptococcus neoformans	Polysaccharide

- Prevent cell from drying out (desiccation)
- It protects the bacterium from the action of lysozyme and bacteriophages.
- Capsule of certain bacteria (e.g. *Bacteroides fragilis)* may be toxic to the host cells and induces abscess formation.
- Biofilm formation and adhesion (see below):

Biofilm Formation

A biofilm is a living ecosystem made of millions of adherent bacterial cells embedded within a self-produced matrix of extracellular polymeric substance (i.e. the polysaccharide slime layer).

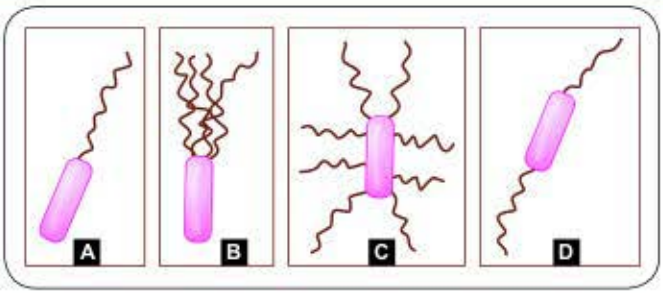
- Persistent biofilms containing pathogenic bacteria are capable of adherence to damaged tissues and plastic surfaces (e.g. medical devices, such as catheters and pacemakers).
- This is the first step in bacterial colonization and sometimes it leads to disease, e.g. prosthetic valve endocarditis and catheter related urinary tract infection (Fig. 2.16).

- **Source of nutrients and energy:** Capsules can be a source of nutrients and energy to microbes. *Streptococcus mutans*, which colonizes teeth, ferments the sugar in the capsule and so formed acid by-products contribute to the tooth decay.
- **Capsules as vaccine:** Capsules of few bacteria are antigenic and anticapsular antibodies are protective in nature. Hence, capsular antigens of many bacteria are used as potential vaccine candidates. Capsular vaccines are available for bacteria, such as pneumococcus, meningococcus and *Haemophilus influenzae* serotype-b.

Demonstration of Capsule

Capsule can be detected by various methods as follows:

- **Negative staining** by India ink and nigrosin stain: Capsule appears as a clear refractile halo around the bacteria where as both the bacteria and the background appear black.
- **M'Faydean capsule stain:** It is used for demonstration of capsule of *Bacillus anthracis* by using polychrome methylene blue stain.
- **Serological test:** Capsular material is antigenic and can be demonstrated by mixing it with a specific anti-capsular serum.
  - Quellung reaction: Capsular serotypes of *Streptococcus pneumoniae* can be detected by adding antisera mixed with methylene blue. Capsule becomes swollen, refractile and delineated.
  - Capsular antigen: It can be detected in the sample (e.g. CSF) by latex agglutination test by using specific anticapsular antibodies coated on latex particles. This is available for pneumococcus, *Cryptococcus, Haemophilus influenzae* and meningococcus.



Figs 2.17A to D: Types of bacterial flagellar arrangement. **A.** Monotrichous; **B.** Lophotrichous; **C.** Peritrichous; **D.** Amphitrichous

Flagella

Flagella are thread-like appendages, protruding from the cell wall, that confer motility to the bacteria (organs of locomotion). They measure 5–20 μm in length and 0.01–0.02 μm in thickness.

Arrangement of Flagella

There are various patterns of arrangement of flagella with respect to the bacterial surface (Fig. 2.17):

- Monotrichous (single polar flagellum), e.g. *Vibrio cholerae, Pseuodmonas* and *Camplylobacter*
- Lophotrichous (multiple polar flagella), e.g. *Spirillum.*
- Peritrichous (flagella distributed over the entire cell surface)—e.g. *Salmonella* Typhi, *Escherichia coli.*
- Amphitrichous (single flagellum at both the ends)—e.g. *Alcaligenes faecalis*

Ultrastructure of Flagella

Electron microscope reveals that the bacterial flagellum is composed of three parts (Fig. 2.18).

1. **Filament:** It is the longest portion of the flagellum that extends from the cell surface to the tip. It is a hollow, rigid cylinder, made up of a single protein **flagellin**.
2. The **basal body:** This is the portion of flagellum which is embedded in the cell. It is the most complex part of a flagellum, made up of 2–4 rings connected to a central rod.
   - In most gram-negative bacteria, there are four rings named as—
     - The outer L and P rings associate with the LPS and peptidoglycan layers, respectively.
     - The inner S ring lies in periplasmic space and M ring contacts the plasma membrane.
   - Gram-positive bacteria have only two basal body rings, an inner ring connected to the plasma membrane and an outer one probably attached to the peptidoglycan.

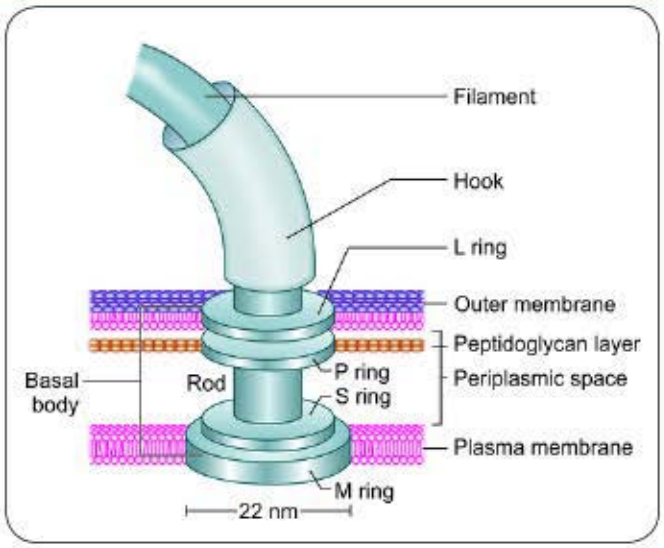


Fig. 2.18: Structure of flagella (gram-negative bacterium)

3. **Hook:** It is a short, curved flexible segment that links the filament to its basal body.

Detection of Flagella

Flagella can be demonstrated by:

- Direct demonstration of flagella
  - Tannic acid staining (Leifson's method and Ryu's method)
  - Dark ground, phase contrast or electron microscope
- Indirect means by demonstrating the motility:
  - Cragie tube method
  - Hanging drop method
  - Semisolid medium, e.g. mannitol motility medium

Bacterial Motility

Bacteria can produce characteristic type of motility which helps in their identification (Table 2.7).

Fimbriae or Pili

Many gram-negative and some gram-positive bacteria possess short, fine, hair-like appendages that are thinner than flagella and not involved in motility, called as fimbriae or pili (singular fimbria or pilus).

- Pili are made up of protein called pilin.
- They are antigenic; however, the antibodies against fimbrial antigens are not protective.
- Fimbriae are very small, measuring 0.5µm long and 10 nm in thickness. A bacterium can have as many as 1,000 fimbriae.

TABLE 2.7: Types of motility shown by different bacteria

Types of motility	Bacteria
Tumbling motility	*Listeria*
Gliding motility	*Mycoplasma*
Stately motility	*Clostridium*
Darting motility	*Vibrio cholerae, Campylobacter*
Swarming motility	*Proteus, Clostridium tetani*
Corkscrew, lashing, flexion extension motility	Spirochete

Functions

- Fimbriae are called the organ of adhesion. This property enhances the virulence of bacteria.
- Certain fimbriae called sex pili also help in bacterial gene transfer.
- Fimbriae are not related to motility and can be found both in motile as well as in nonmotile organisms.

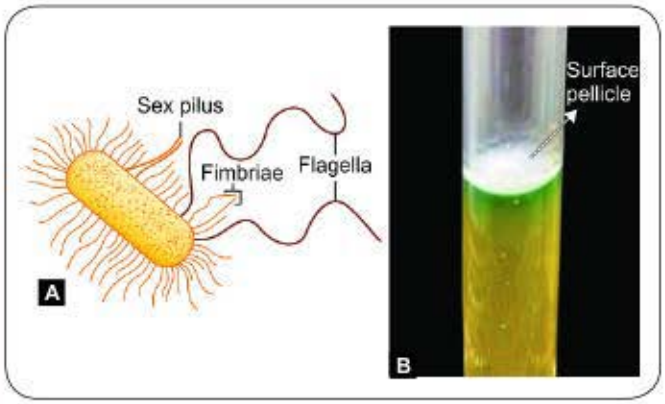
Types

Different types of fimbriae are as follows (Fig. 2.19A)—

- **Common pili:** There are six types of common pili depending on their morphology, number per cell, adhesive properties and antigenic nature.
- **Sex or F (fertility) pili:** Sex pili are special type of large fimbriae present 1–10 per cell (e.g. as found in gonococcus). Sex pili help in bacterial conjugation. They are present in male bacterium; form the conjugation tube in male bacterium and thereby help in transfer of genetic material from male bacteria to the female bacteria via the conjugation tube.
- Col I (colicin) pili.

Detection of Fimbriae

Electron microscopy is the only method for direct demonstration of fimbriae. However, there are some indirect methods to know the presence of fimbriae such as:



Figs 2.19A and B: A. Differentiation between fimbriae, sex pilus and flagella; **B.** Surface pellicle (arrow showing)

- **Hemagglutination:** Many fimbriated bacteria (e.g. *Escherichia coli, Klebsiella*) strongly agglutinate with red blood cells of guinea pigs, fowl, horses and pigs. This property of hemagglutination is a simple method for detecting the presence of fimbriae. In some bacteria, the hemagglutination may be specifically inhibited by D-mannose.
- **Surface pellicle:** Some aerobic fimbriated bacteria form a thin layer at the surface of a broth culture called as **pellicle.** The pellicle consists of many aerobic bacteria that adhere to the surface by their fimbriae (Fig. 2.19B).

Atypical Forms of Bacteria

- **Involution forms:** They are swollen and aberrant forms of bacteria (e.g. gonococci and *Yersinia pestis*) formed in ageing cultures in high salt concentration.
- **Pleomorphic bacteria:** Some bacteria exhibit great variation in the shape and size of individual cells, e.g. *Proteus* and *Haemophilus*. This is known pleomorphism.
- **Cell wall deficient forms:** *See below*

Pleomorphism and involution forms are often caused by defective cell wall synthesis. Involution forms may also be formed due to the activity of autolytic enzymes.

L Form (Cell Wall Deficient Forms)

L forms are the cell wall deficient bacteria, discovered by E. Klieneberger, while studying *Streptobacillus moniliformis*

- She named it as L form after its place of discovery, i.e. Lister Institute, London (1935).
- When bacteria loose cell wall, they become spherical irrespective of original shape. This may occur spontaneously or after exposure to penicillin or lysozyme.
- L forms play a role in the persistence of pyelonephritis and other chronic infections.

Types of L forms

Two types of L forms are distinguished:

- **Unstable L forms:** Bacteria lose the cell wall in presence of penicillin, a mechanism of resistance shown by the bacteria against penicillin. Such L forms are maintained only in presence of penicillin. They are capable of dividing, but can revert back to the original morphology once penicillin is removed.
  - Protoplasts: They are gram-positive bacteria whose cell wall is entirely removed
  - Spheroplasts: They are derived from gram-negative bacteria whose cell wall is partially removed.
- **Stable L forms:** L forms that are unable to revert to the original bacteria are called stable L forms.
  - *Mycoplasma* do not have a true cell wall; the peptidoglycan layer is replaced by sterol.
  - It is postulated that *Mycoplasma* may represent stable L forms of a yet to be identified parent bacteria.
  - But many researchers do not consider *Mycoplasma* as L forms, since they are not derived from bacteria that normally have cell walls.

BACTERIAL SPORES

Spores are highly resistant resting (or dormant) stage of the bacteria formed in unfavorable environmental conditions as a result of the depletion of exogenous nutrients. Bacterial spores formed within the parent cell, are called endospores and the remaining part of the bacteria is called the sporangium.

Structure: Bacterial spore comprises of several layers. From innermost towards the outermost, the layers are: core → cortex → coat → exosporium (Fig. 2.20A).

- The **core** is the inner most part containing the DNA material and is walled off from the cortex by an inner membrane and the germ cell wall.
- Cortex and the coat layers lie external to the core, and are separated from each other by an outer membrane.
- The outermost layer is called as the exosporium.

Sporulation

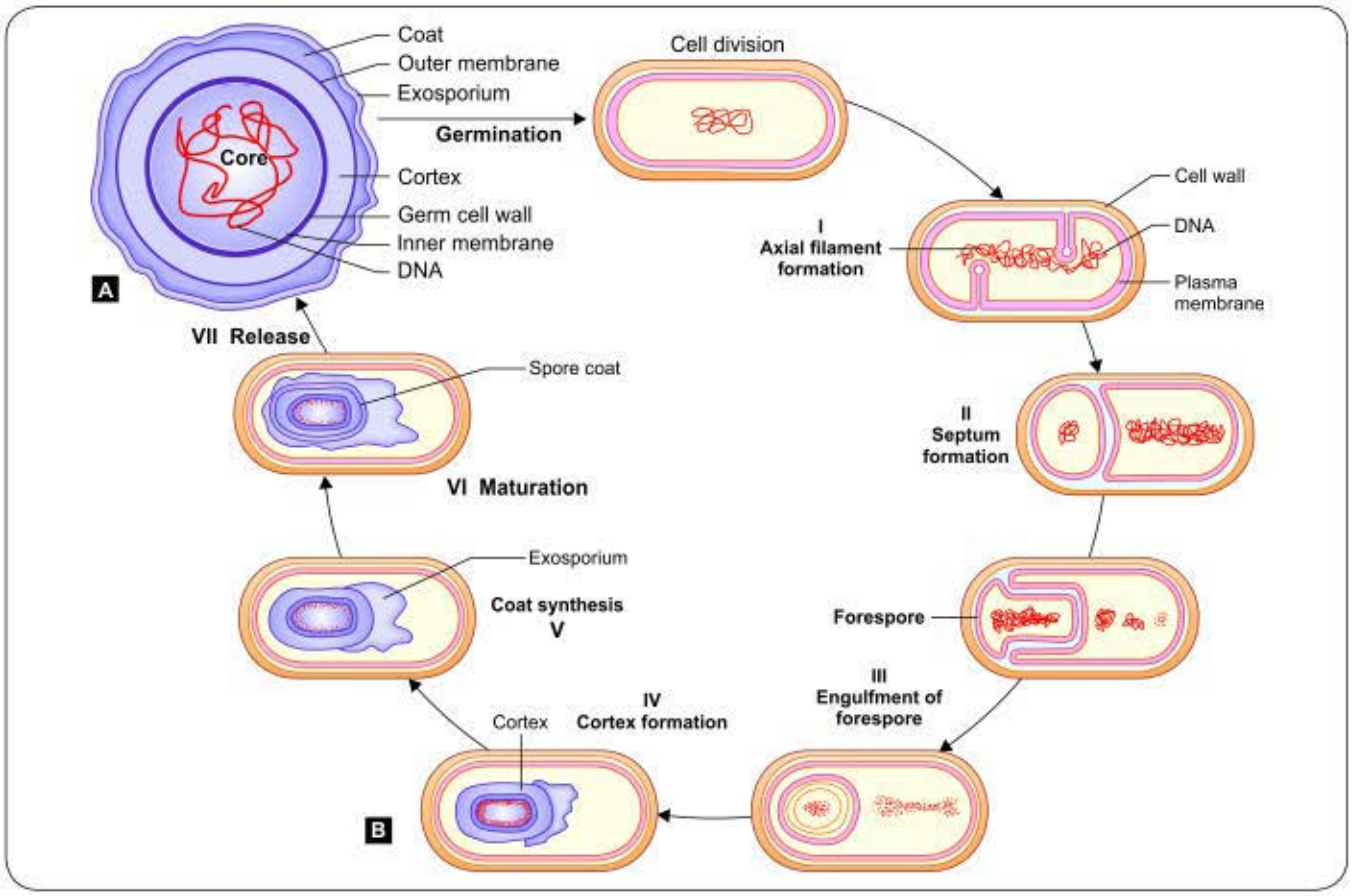
Sporulation (or sporogenesis) refers to the process of formation of spores from vegetative stage of bacteria. It is not a method of reproduction because the bacteria do not divide during sporulation. Sporulation commences when growth ceases due to lack of nutrients. It is a complex process, takes about 10 hours which may be divided into seven stages (Fig. 2.20B).

1. **Stage I (axial filament formation):** Bacterial cell division occurs and an axial filament of nuclear material is formed.
2. **Stage II (septum formation):** Cell membrane is folded inwards to enclose part of the DNA and to produce the forespore septum.
3. **Stage III (engulfment of forespore):** The membrane continues to grow and engulfs the immature spore in a second membrane.
4. **Stage IV:** The cortex synthesis occurs in the space between the two membranes with deposition of calcium and dipicolinic acid.
5. **Stage V:** Formation of protein coat and exosporium around the cortex
6. **Stage VI:** Maturation of the spore occurs; acquiring properties of heat resistance and refractility.
7. **Stage VII (release):** Finally, lytic enzymes destroy the sporangium releasing the spore.

Germination

It is the transformation of dormant spores into active vegetative cells when grown in a nutrient-rich medium. It comprises of three stages:

- **Activation:** It is reversible process that prepares spores for gerimantion and usually results from treatments like heating.
- **Germination:** It is the process of breaking of the spore's dormant state, characterized by spore swelling, rupture



Figs 2.20A and B: **A.** Structure of bacterial spore; **B.** Steps of sporulation

or absorption of the spore coat, loss of resistance to heat and other stresses, loss of refractility, release of spore components, and increase in metabolic activity.

- **Outgrowth:** The spore protoplast emerges from the remains of the spore coat, and develops into an active bacterium.

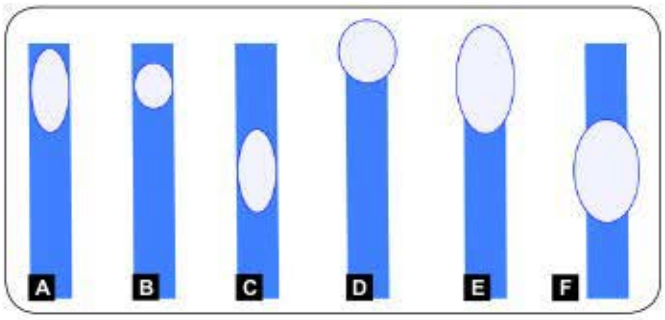
Shape and Position of Spores

For a given species, the precise position, shape and relative size of the spore are constant.

- **Position:** Spores may be central, subterminal or terminal (Fig. 2.21).
- **Shape:** They may be oval or spherical in shape.
- **Width:** The diameter of spore may be same or less than the width of bacteria (non-buldging spore—e.g. as in *Bacillus*), or may be wider than the bacillary body producing a distension or bulge in the cell (buldging spore, e.g. as in *Clostridium*).

Sporicidal Agents

Spores are resistant to most of the routinely used disinfectants. Only limited sterilization methods are available to kill the spores (refer Chapter 3).



Figs 2.21A to F: Position and shape of spores. **A.** Non-bulging, oval and terminal; **B.** Non-bulging, round, and subterminal; **C.** Non-bulging, oval and central; **D.** Bulging, round and terminal; **E.** Bulging, oval and terminal; **F.** Bulging, oval, and central

Demonstration of Spores

- **Gram staining:** Spores appear as unstained refractile bodies within the cells.
- **Modified Ziehl–Neelsen staining:** Spores are weakly acid-fast and appear red color when ZN staining is performed using 0.25% sulpfuric acid as decolorizer.
- **Special techniques** for endospore staining include the Schaeffer–Fulton stain and the Moeller stain.

Applications

- Spores of certain bacteria are employed as indicators for proper sterilization. Absence of the spores after autoclaving or processing in hot air oven indicates proper sterilization.
  - Spores of *Geobacillus stearothermophilus* are used as sterilization control for autoclave.
  - Spores of non-toxigenic strains of *Clostridium tetani* are used as sterilization control for hot air oven.
- Spores have also been used as agents of bioterrorism, e.g. endospores of *Bacillus anthracis* were used in the 2001 anthrax bioterrorism attacks.

PHYSIOLOGY OF BACTERIA

BACTERIAL GROWTH AND NUTRITION

Bacterial Growth Requirement

Water constitutes about 80% of total bacterial cell. The minimum nutritional requirements that are essential for growth and multiplication of bacteria include sources of carbon, nitrogen, hydrogen, oxygen and some inorganic salts (such as small amounts of sulfur, phosphorus and other elements like sodium, potassium, magnesium, iron and manganese).

Bacterial Vitamin

Some fastidious bacteria do not grow in the routine culture medium unless certain organic compounds (that are essential to those bacteria) are added to the medium. These are known as growth factors or bacterial vitamins. In most instances, bacterial vitamins are same as the vitamins necessary for mammalian nutrition, particularly those belonging to the vitamin B group–thiamine, nicotinic acid, riboflavin, pyridoxine, folic acid and vitamin B12 (Table 2.8).

Bacterial Cell Division

Bacteria divide by a relatively simple form of cell division, i.e. by binary fission. The cell division commences when a bacterial cell reaches a critical mass in its cellular constituents. The nuclear division precedes cytoplasmic division.

- **Nuclear division:** The two strands of bacterial DNA are separated and then they replicate to form new complementary strands. Thus two identical molecules of ds DNA are formed.
- **Cytoplasmic division:** A transverse septum grows across the cell from the cell membrane, following which the cell wall materials are deposited and then the two daughter cells get separated.
- In few bacteria, the daughter cells may remain partially attached even after cell division; so that the bacterial cells are arranged in pair or in chain (e.g. streptococci) or in clusters (e.g. staphylococci).

TABLE 2.8: Bacterial vitamins

Vitamins	Bacteria requiring vitamin
Biotin	*Leuconostoc* species
Cyanocobalamin (B12)	*Lactobacillus* species
Folic acid	*Enterococcus faecalis*
Pantothenic acid	*Morganella morganii*
Pyridoxine (B6)	*Lactobacillus* species
Niacin (nicotinic acid)	*Brucell abortus, Haemophilus influenzae*
Riboflavin (B2)	*Bacillus anthracis*

Rate of Multiplication in Bacteria

Generation time is the time required for a bacterium to give rise to two daughter cells under optimum condition. The generation time for different bacteria is as follows:

- *Escherichia coli* and most of the other pathogenic bacteria—20 minutes
- *Mycobacterium tuberculosis*—20 hours
- *Mycobacterium leprae*—20 days

As bacteria grow so rapidly and by geometric progression, a single bacterium can theoretically give rise to 10^{21} daughter cells in 24 hours. Fortunately, it does not happen in reality, because the bacterial multiplication is arrested after a few cell divisions due to exhaustion of nutrients and accumulation of toxic products.

Bacterial Count

Bacterial count may be expressed in terms of total count and viable count.

- **Total count:** It indicates total number of bacteria (live or dead) in the specimen. This is done by counting the bacteria under microscope using counting chamber.
- **Viable count:** It measures the number of living (viable) cells in the given specimen. Viable count may be obtained by—
  - Pour plate method (described in Chapter 4)
  - Surface viable count by spreading method
  - Surface viable count by Miles and Misra method.

Bacterial Growth Curve

When a bacterium is inoculated into a suitable liquid culture medium and incubated, its growth follows a definite course. When bacterial count of such culture is determined at different intervals and plotted in relation to time, a **bacterial growth curve** is obtained comprising of four phases (Fig. 2.22, Table 2.9).

1. **Lag phase:** It is the period between inoculation and beginning of multiplication of bacteria. After

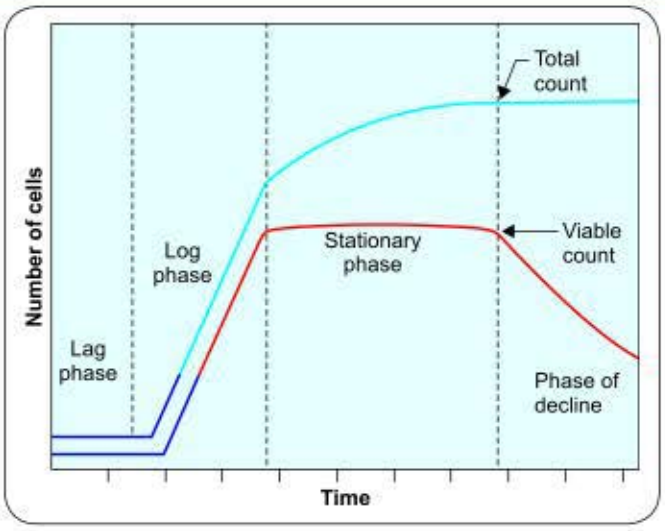


Fig. 2.22: Bacterial growth curve

TABLE 2.9: Various phases of bacterial growth curve

	Lag	Log	Stationary	Decline
Bacteria divide	No	Yes	Yes	No
Bacterial death	No	No	Yes	Yes
Total count	Flat	Raises	Raises	Flat
Viable count	Flat	Raises	Flat	Falls
Special features	▪ Accumulation of enzymes and metabolites ▪ Attains maximum size	▪ Uniformly stained ▪ Metabolically active ▪ Small size	▪ Gram variable ▪ **Produce:** Granules Spores Exotoxin, Antibiotics Bacteriocin	**Produce:** Involution forms

inoculating into a culture medium, bacteria do not start multiplying immediately, but take some time to build-up enzymes and metabolites.

- Bacteria increase in size due to accumulation of enzymes and metabolites.
- Bacteria reach their maximum size at the end of lag phase.

2. **Logphase:** In this phase bacteria divide exponentially so that the growth curve takes a shape of straight line. At this stage, the bacterium is—
   - Smaller in size
   - Biochemically active: It is the best stage to perform the biochemical reactions
   - Uniformly stained: It is the best time to perform the Gram stain
3. **Stationary phase:** After the log phase, the bacterial growth ceases almost completely due to exhaustion of nutrients, accumulation of toxic products and autolytic enzymes.
   - The number of progeny cells formed is just enough to replace the number of cells that die.
   - Hence, the number of viable cells remain stationary as there is almost a balance between the dying cells and the newly formed cells. But the total count keeps rising. In this phase:
     - Bacterium becomes Gram variable
     - More storage granules are formed
     - Sporulation occurs in this phase
     - Bacteria produce exotoxins, antibiotics and bacteriocins.
4. **Decline phase:** Gradually, the bacteria stop dividing completely; while the cell death continues due to exhaustion of nutrients, and accumulation of toxic products.
   - There is decline in viable count and not in total count.
   - Involution forms are seen.

Continuous Culture

It is a special type of culture, which supports the bacterial growth in a particular phase (e.g. log phase) for longer period continuously without depletion of nutrients or without accumulation of toxic products.

- Special devices are used which supply the replenishing nutrients and remove the dying bacterial cells and their toxic products.
- Continuous cultures can be maintained mainly by two methods.
  - Turbidostat culture
  - Chemostat culture
- Continuous culture of bacteria is required sometimes for industrial and research purposes.

Bacterial Growth *in Vivo*

When bacteria multiply in host tissues, the situation may be intermediate between a routine culture (batch culture) and a continuous culture. The source of nutrients may be plenty, but the defence mechanisms of the body influence the bacterial growth *in vivo*.

FACTORS AFFECTING GROWTH OF BACTERIA

There are several environmental factors that affect the growth of the bacteria.

Oxygen

On basis of their oxygen requirements bacteria are classified as:

- **Obligate aerobes:** They can grow only in the presence of oxygen (e.g. *Pseudomonas, Mycobacterium tuberculosis, Bacillus, Brucella* and *Nocardia).*

- **Facultative anaerobes:** They are aerobes that can also grow anaerobically (e.g. most of the pathogenic bacteria, e.g. *E. coli, S. aureus*, etc.).
- **Facultative aerobes:** They are anaerobes that can also grow aerobically (e.g. *Lactobacillus*).
- **Microaerophilic bacteria:** They can grow in the presence of low oxygen tension, i.e. 5–10% of oxygen (e.g. *Campylobacter* and *Helicobacter*).
- **Obligate anaerobes:** These bacteria can grow only in absence of oxygen, as oxygen is lethal to them (e.g. *Clostridium).*
- **Aerotolerant anaerobe:** They can tolerate oxygen for some time, but do not use it (*Clostridium histolyticum).*

Carbon Dioxide

Organisms that require higher amounts of carbon dioxide (5–10%) for growth are called **capnophilic bacteria**. Examples include *Brucella abortus, Streptococcus pneumoniae*, etc.

Temperature

Most of the pathogenic bacteria grow optimally at 37°C (i.e. human body temperature). However, the optimal temperature range varies with different bacterial species. Accordingly bacteria can be grouped into:

- **Psychrophiles:** These grow best at temperatures below 20°C; example, most of the saprophytes.
- **Mesophiles:** These grow within a temperature range 25°C and 40°C; example, most of the pathogenic bacteria
- **Thermophiles:** These bacteria grow at a high temperature range of 55°C–80°C e.g. *Bacillus stearothermophilus.*

pH

Most pathogenic bacteria grow between pH 7.2–pH 7.6**.** Very few bacteria (e.g. lactobacilli) can grow at acidic pH below pH 4, while bacteria such as *Vibrio cholerae* are capable of growing at alkaline pH (8.2–8.9).

Light

Bacteria (except phototrophs) grow well in darkness. They are sensitive to ultraviolet rays and other radiations in light. Photochromogenic mycobacteria produce pigments only on exposure to light.

Osmotic Effect

Bacteria are able to withstand a wide range of external osmotic variation because of the mechanical strength of the cell wall.

- Sudden exposure of bacteria to hypertonic solutions may cause plasmolysis—osmotic withdrawal of water leading to shrinkage of protoplasm. This occurs more readily in gram-negative than in gram-positive bacteria.
- Sudden transfer of bacteria from concentrated solution to distilled water may cause plasmoptysis—excessive osmotic imbibition of water, leading to swelling and rupture of the cell.

Mechanical and Sonic Stresses

Though bacteria have tough cell walls, they may be ruptured and disintegrated by vigorous shaking with glass beads and by exposure to ultrasonic vibrations.

Moisture and Desiccation

Moisture is an essential requirement for the growth of bacteria because 80% of the bacterial cell consists of water. However, the drying has varying effects on different organisms.

- Some organisms like *Treponema pallidum* and *N. gonorrhoeae* die quickly after drying, while *M. tuberculosis* and *Staphylococcus aureus* may survive drying for several weeks.
- Drying in cold and vacuum (lyophilization) is used for preservation of microorganisms.

BACTERIAL METABOLISM

Bacterial metabolism is the process by which a microbe obtains the energy and nutrients (e.g. carbon) for its survival and reproduction. Bacterial metabolism can be based on three principles:

1. How the bacteria obtain carbon for synthesizing cell mass?
   - **Autotrophs:** These bacteria can synthesize all their organic compounds by using atmospheric CO_2 as their sole source of carbon.
   - **Heterotrophs:** They use reduced, preformed organic molecules as carbon sources.
2. How the bacteria obtain reducing equivalents (electrons) used either in energy conservation or in biosynthetic reactions?
   - **Lithotrophs:** These bacteria obtain reducing equivalents (electrons) from inorganic compounds.
   - **Organotrophs:** They obtain reducing equivalents from organic compounds.
3. How bacteria obtain energy for living and growing?
   - **Chemotrophs:** These bacteria obtain energy from external chemical compounds.
   - **Phototrophs:** They obtain energy from light.

Bacteria usually possess combination of these properties. Most of the pathogenic bacteria fall into **chemoorganoheterotrophs** group. These bacteria obtain energy, carbon, and reducing equivalents for biosynthetic reactions from organic compounds, e.g. *Escherichia coli.*

Metabolism of Pathogenic Bacteria

The bacterial metabolism is dependent on whether they are aerobic or anaerobic.

- Aerobic bacteria utilize glucose by oxidation
- Whereas the anaerobes utilize glucose by fermentation.

Fermentation

Utilization of glucose under anaerobic condition is called fermentation. Bacterial fermentation occurs via three pathways:

1. **Glycolysis** (also called EMP or Embden–Meyerhof-Parnas pathway): Glucose is converted to pyruvate; seen in most of the bacteria.
2. **Entner–Doudoroff (ED) pathway:** It is rarely seen in few bacteria such as *Pseudomonas*. Here, the glucose is converted to KDPG (keto-deoxy-phosphogluconate) which is then further converted into pyruvate.

3. **Pentose phosphate pathway:** It seen in most of the bacteria; glucose is converted to pentose sugars, such as xylulose phosphate and ribulose phosphate which are used in the biosynthesis of aromatic amino acids, vitamin B6 and ribose 5-phosphate, which is a major component of nucleic acids.

Utilization of Pyruvate

Pyruvate produced at the end of EMP and ED pathways are further utilized in many ways (as given below) to produce acids (lactic acid, formic acid, pyruvic acid), gas (hydrogen, carbon dioxide) and alcohols.

- **Homolactic fermentation** produces lactic acid. This is seen in enterococci, streptococci and lactobacilli.
- **Heterolactic fermentation** produces ethanol. This is seen in *Leuonostoc*, lactobacilli and yeast.
- **Mixed acid fermentation:** Pyruvate is metabolized to produce a number of different products, such as acetic acid, ethanol, succinic acid and formic acid. The nature and amount of acid production depends on the organism.
- **Butanediol fermentation:** Pyruvate is metabolized to acetoin, which is further converted to butanediol. This is produced by *Klebsiella* and few other bacteria. Production of acetoin is detected by an important biochemical test called Voges–Proskauer reaction.
- **Butanol formation:** It is seen in anaerobic bacteria *Clostridium*
- **Propionic acid formation:** This is observed in anaerobic bacteria, such as *Bacteroides*, and *Propionibacterium*.

During fermentation, energy rich phosphate molecules are produced as by-products which convert adenosine diphosphate (ADP) to adenosine triphosphate (ATP). This process is known as **substrate-level phosphorylation**.

- During glycolysis, net of 2 ATP molecules per mole of glucose are produced.
- Fermentation is carried out by both obligate and facultative anaerobes.

Oxidation

Oxidation refers to oxidative utilization of glucose (by Krebs cycle) followed by production of ATP via oxidative phosphorylation and transfer of electrons in electron transport system.

- **Kerbs cycle:** The pyruvic acid produced at the end of glycolysis and ED pathway undergoes a series of oxidative decarboxylation steps to produce a number of high energy compounds, such as nicotinamide adenine dinucleotide phosphate (NADPH) and flavin adenine dinucleotide (FADH) which finally enter the electron transport system.
- **Electron transport system:** It is located in cell membrane of bacteria, in contrast to mitochondria of eukaryotes.
  - It consists of alternating hydrogen and electron carriers located in a sequence across the cell membrane.
  - Transfer of protons down the electron transport system creates a membrane potential. The energy of this potential is harnessed by ATP synthase which catalyses the formation of ATP from ADP.
  - Krebs cycle results in a net gain of 38 ATP molecules per mole of glucose.

EXPECTED QUESTIONS

I. Essay:

1. Describe in detail the structure and function of the cell wall and cell membrane of a gram-negative rod with the help of a diagram.

II. Write short notes on:

1. Bacterial capsule
2. Bacterial spore
3. Principle and uses of dark field microscope
4. Principle and uses of fluorescent microscope
5. Principle and uses of electron microscope
6. Bacterial growth curve
7. Bacterial flagella

III. Multiple Choice Questions (MCQs):

1. Cuneiform arrangement is characteristic of:
a. *Staphylococcus* b. *Streptococcus*
c. *Corynebacterium diphtheriae*
d. *Bacillus anthracis*

2. Electrons are used as a source of illumination in:
a. Light microscope
b. Dark field microscope
c. Phase contrast microscope
d. Electron microscope

3. All of the following are acid-fast except:
a. *Mycobacterium tuberculosis*
b. *Nocardia* c. *Isospora belli*
d. *Staphylococcus*

4. Bacterial capsule can be best demonstrated by:
a. Gram staining b. Acid-fast staining
c. Negative staining d. Albert staining

5. Lipopolysaccharide is a component of cell wall of:
a. Gram-positive bacteria
b. Gram-negative bacteria
c. Virus d. Fungi

6. Bacterial structure involved in respiration is:
a. Ribosome b. Pili
c. Mesosome d. Flagella

Answers

1. c **2.** d **3.** d **4.** c **5.** b **6.** c

CHAPTER 3

Sterilization and Disinfection

Chapter Preview

- Introduction
- Agents used for sterilization/ disinfection
  - Physical agents
  - Chemical agents
- Testing of disinfectants
- Spaulding's classification of medical devices

INTRODUCTION

Sterilization, disinfection, asepsis and decontamination are the four separate but interrelated terminologies, all aiming at removing or destroying the microorganisms from materials or from body surfaces.

Sterilization

Sterilization is a process by which all living microorganisms, including viable spores, are either destroyed or removed from an article, body surface or medium.

- It results in reduction of at least 10^6 log colony-forming units of microorganisms and their spores.
- It can be achieved by a physical agent or a chemical agent (called chemical sterilant).

Disinfection

It refers to a process that destroys or removes most if not all pathogenic organisms but not bacterial spores.

- It results in reduction of at least 10^3 log colony-forming units of microorganism, but not spores.
- The primary goal in disinfection is to destroy potential pathogens, but it also substantially reduces the total microbial population.
- **Agents:** Disinfection can also be achieved by a physical agent or a chemical agent (called disinfectant) and they are normally used only on inanimate objects, not on body surfaces.

Asepsis

It is a process where the chemical agents (called antiseptics) are applied on to the body surfaces (skin), which kill or inhibit the microorganisms present on skin.

- They prevent the entry of pathogens into sterile tissues and thus prevents infection or sepsis.
- However, they are generally not as toxic as disinfectants as they must not destroy too much of host tissue.

Decontamination (or Sanitization)

It refers to the reduction of pathogenic microbial population to a level at which items are considered as safe to handle without protective attire.

- It results in reduction of atleast 1 log colony-forming unit of most of the microorganisms, but not spores.
- Examples include manual or mechanical cleaning by soap and detergents to eliminate debris or organic matter from the medical devices.

The agent used for sterilization/disinfection can also be named with suffix based on whether they kill or inhibit the microorganisms.

- Suffix 'cide' is used for the agents that can kill microorganisms. Examples include bactericide, virucide and fungicide.
- Suffix 'static' is used for the agents that do not kill; but inhibit the microbial growth. If these agents are removed, growth will resume- for example, bacteriostatic and fungistatic.

Although these agents have been described in terms of their effects on pathogens, it should be noted that they also kill or inhibit the growth of nonpathogens as well.

Factors Influencing Efficacy of Sterilant/Disinfectant

The efficiency of a sterilant/disinfectant is affected by at least seven factors.

1. **Organism load:** Larger microbial population requires a longer time to die than a smaller one.
2. **Nature of organisms:** It greatly influences the efficacy of the disinfectants or sterilizing agents.

The decreasing order of resistance of microorganisms to disinfectant or sterilizing agents is as follows—

Prions (highest resistance) > *Cryptosporidium* oocysts > Bacterial spores > Mycobacteria > Other parasite cysts (e.g. *Giardia*) > Small non-enveloped viruses > Trophozoites > Gram-negative bacteria > Fungi > Large non-enveloped viruses > Gram-positive bacteria > Enveloped viruses.

3. **Concentration** of the chemical agent or the temperature of heat sterilization.
4. **Nature of the sterilant/disinfectant such as its:**
   - Microbicidal ability
   - Rapidity of action
   - Ability to act in presence of organic matter
   - Residual activity
5. **Duration of exposure:** More is the exposure time to sterilant/disinfectant, better is the efficacy.
6. **Temperature:** An increase in the temperature at which a chemical acts often enhances its activity. A lower concentration of disinfectant or sterilizing agent can be used at a higher temperature.
7. **Local environment:** The microorganisms to be controlled are not isolated but surrounded by environmental factors that may either offer protection or aid in its destruction, e.g.
   - **pH:** Heat kills more readily at an acidic pH.
   - **Organic matter:** Presence of organic matter, such as pus, blood, and stool can protect the organisms against heating and chemical agents.
     - It may be necessary to mechanically clean an object (e.g. syringes and medical equipments) before it is disinfected or sterilized.
     - Materials containing organic substances require more time or volume or concentration of chemical agent for sterilization/disinfection. More chlorine must be added to disinfect drinking water if a city's water supply has a high content of organic material.
   - **Biofilm:** Formation of biofilm is another mechanism which prevents the entry of disinfectants to act on the microorganisms which are embedded inside the biofilm.

Both physical and chemical methods are used to achieve control of microorganisms (Table 3.1).

TABLE 3.1: Classification of sterilization/disinfection methods

Physical methods	
Drying	
Heat	
Dry heat: ▪ Flaming ▪ Incineration ▪ Hot air oven	Moist heat: ▪ Temperature below 100°C, e.g. pasteurization, water bath and inspissation ▪ Temperature at 100°C, e.g. boiling, steaming and tyndallization ▪ Temperature above 100°C, e.g. autoclave
Filtration: Depth filters and membrane filters	
Radiation ▪ Ionizing radiation: γ rays, X-rays and cosmic rays ▪ Nonionizing radiation: Ultraviolet (UV) and infrared rays	
Ultrasonic vibration	
Chemical methods	
Alcohols: Ethyl alcohol, isopropyl alcohol	
Aldehydes: Formaldehyde, glutaraldehyde, Ortho-phthaladehyde	
Phenolic compounds: Cresol, lysol, chlorhexidine, chloroxylenol, hexachlorophene	
Halogens: Chlorine, iodine, iodophors	
Oxidizing agents: Hydrogen peroxide, peracetic acid	
Salts: Mercuric chloride, copper salts	
Surface active agents: Quaternary ammonium compounds and soaps	
Dyes: Aniline dyes and acridine dyes	
Gas sterilization: ▪ Low temperature steam formaldehyde ▪ Ethylene oxide (ETO) ▪ Betapropiolactone (BPL) ▪ Plasma sterilization	

Note: Sometimes the words sterilization and disinfection are loosely used to describe physical and chemical agents respectively. However, this practice is incorrect, because there are some physical agents that do not produce complete sterilization; similarly many chemical agents are there that may kill the spores and produce sterilization.

PHYSICAL AGENTS OF STERILIZATION/DISINFECTION

Drying

Moisture is essential for the growth of bacteria. 70–80% of the weight of the bacterial cell is due to water. Drying, therefore has a deleterious effect on many bacteria. Both drying and sunlight are not reliable. They do not affect many microbes, including spores.

Heat

Heat is the most reliable and commonly employed method of sterilization/disinfection. It should be considered as the method of choice unless contraindicated. Two types of heat are used, dry heat and moist heat.

Mechanism of action heat:

- Dry heat kills the organisms by charring, denaturation of bacterial protein, oxidative damage and by the toxic effect of elevated levels of electrolytes.
- Moist heat kills the microorganisms by denaturation and coagulation of proteins.
- Materials containing organic substances require more time for sterilization/disinfection.

Dry Heat

Flaming

Items are held in the flame of a Bunsen burner either for long time or short time.

- Longer time exposure in flame till they become red hot: This is done for inoculating wires or loops, tips of forceps, etc.
- For shorter period of time without allowing the items to become red hot: This is done for fragile items, e.g. mouth of test tubes.

Incineration

Incineration is used for the disposal of biomedical waste materials. It burns (sterilizes) the anatomical waste and microbiology waste by providing a very high temperature 870–1,200°C and thereby converting the waste into ash, flue gas and heat.

Hot Air Oven

Hot air oven is the most widely used method of sterilization by dry heat. It is electrically heated and is fitted with a fan to ensure adequate and even distribution of hot air in the chamber (Fig. 3.1). It is also fitted with a thermostat which maintains the chamber air at a chosen temperature.

- **Temperature:** A holding temperature and time of 160°C for 2 hours is required for sterilization in hot air oven.
- **Materials sterilized:** Hot air oven is the best method for sterilization of—
  - Glassware like glass syringes, petri dishes, flasks, pipettes and test tubes.
  - Surgical instruments like scalpels, forceps, etc.
  - Chemicals, such as liquid paraffin, fats, glycerol, and glove powder, etc.

Fig. 3.1: Hot air oven

- **Precautions:** The following precautions should be taken while using hot air oven.
  - Overloading of hot air oven should be avoided.
  - The material should be arranged in a manner so that free circulation of air is maintained.
  - Material to be sterilized should be dried completely.
  - Cotton plugs should be used to close the mouths of test tubes, flasks, etc.
  - Paper wrapping of the items should be done.
  - Any inflammable material like rubber (except silicone rubber) should not be kept inside the oven.
  - The oven must be allowed to cool for two hours before opening the doors, since the glassware may crack by sudden cooling.
- **Sterilization control:** The effectiveness of the sterilization done by hot air oven can be monitored by:
  - Biological indicator: Spores (10^6) of nontoxigenic strains of *Clostridium tetani* or *Bacillus subtilis* subspecies *niger* are used to check the effectiveness of sterilization by hot air oven. These spores should be destroyed if the sterilization is done properly.
  - Thermocouples: It is a temperature measuring device that records the temperature by a potentiometer.
  - Browne's tube: It contains a heat sensitive red dye which turns green after being exposed to certain temperature for a definite period of time. It was invented by Albert Browne in 1930.

Moist Heat

Moist heat kills the microorganisms at a lower temperature than dry heat. Moist heat may be used at different temperatures as follows.

Moist Heat at a Temperature Below 100°C

- **Pasteurization:** It is method used for control of microorganisms from beverages like fruit and vegetable juices, beer, and dairy products, such as milk.
  - Two methods are available–Holder method (63°C for 30 minutes) and Flash method (72°C for 20 seconds followed by rapid cooling to 13° or lower).
  - All nonsporing pathogens, including mycobacteria, brucellae and salmonellae are killed except *Coxiella burnetii* which being relatively heat resistant may survive in holder method.
- **Water bath:** It is used for disinfection of serum, body fluids and vaccines (Fig. 3.2).
  - Bacterial vaccines are disinfected at 60°C for 1 hour.
  - Serum or heat labile body fluids can be disinfected at 56°C for one hour.
- **Inspissation (fractional sterilization):** It is a process of heating an article on 3 successive days at **80–85°C for 30 minutes** by a special instrument called inspissator (Fig. 3.3).

Fig. 3.2: Water bath

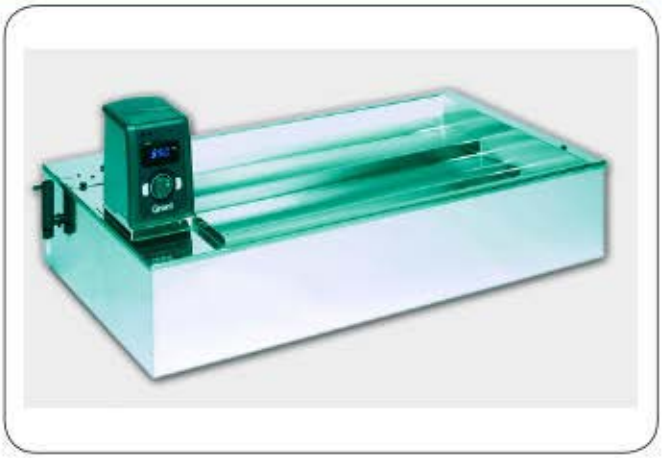

Fig. 3.3: Inspissator

- Working principle: In inspissator, the first exposure kills all the vegetative forms, and in the intervals between the heatings the remaining spores germinate into vegetative forms which are then killed on subsequent heating.
- Uses: Inspissation is useful for sterilization of egg and serum based media which generally get destroyed at higher temperature.
  - Egg based media—e.g. Lowenstein-Jensen medium and Dorset's egg medium.
  - Serum based media—e.g. Loeffler's serum slope.

Moist Heat at a Temperature of 100°C

- **Boiling:** Boiling of the items in water for 15 minutes may kill most of the vegetative forms but not the spores, hence not suitable for sterilziation of surgical instruments. Though boiling is a simple, easily available option to most people; however, boiling can be hazardous and not effective; hence should not be used if better methods are feasible.
- **Steaming:** Koch's or Arnold's steam sterilizer are useful for those media which are decomposed at high temperature of autoclave.
  - The articles are kept on a perforated tray through which steam can pass.
  - They are exposed to steam (100°C) at atmospheric pressure for 90 minute.
  - Most of the vegetative forms are killed by this method except thermophiles and spores.
- **Tyndallization or intermittent sterilization** (named after John Tyndall) involves steaming at 100°C for 20 minutes for 3 consecutive days.
  - The principle is similar to that of inspissation, except that here, the temperature provided is 100°C, instead of 80°C.
  - It is used for sterilization of gelatin and egg, serum or sugar containing media, which are damaged at higher temperature of autoclave.

Moist Heat at a Temperature above 100°C (Autoclave)

Principle of Autoclave

Autoclave functions similar to a pressure cooker and follows the general laws of gas.

- Water boils when its vapor pressure equals that of the surrounding atmosphere. So, when the atmospheric pressure is raised, the boiling temperature is also raised.
- At normal pressure, water boils at 100°C but when pressure inside a closed vessel increases, the temperature at which water boils also increases.

Components of Autoclave

Autoclave comprises of three parts: a pressure chamber, a lid and an electrical heater.

- Pressure chamber consists of—
  - It is a large cylinder (vertical or horizontal) in which the materials to be sterilized are placed. It is made up of gunmetal or stainless steel and placed in a supporting iron case
  - A steam jacket (water compartment)
- The lid is fastened by screw clamps and rendered air tight by an asbestose washer. The lid bears the following-
  - A discharge tap for air and steam discharge
  - A pressure gauge (sets the pressure at a partcular level)
  - A safety valve (to remove the excess steam)
- An electrical heater is attached to the jacket; that heats the water to produce steam.

Procedure

The cylinder is filled with sufficient water and the material to be sterilized is placed inside the pressure chamber. The lid is closed and the electrical heater is put on. The safety valve is adjusted to the required pressure.

- After the water boils, the steam and air mixture is allowed to escape through the discharge tap till all the air has been displaced.
  - This can be tested by passing the steam-air mixture liberated from the discharge tap into a pail of water through a connecting rubber tube.
  - When the air bubbles stop coming in the pail, it indicates that all the air has been displaced by steam. The discharge tap is then closed.
- The steam pressure rises inside and when it reaches the desired set level [e.g. 15 pounds (lbs) per square inch in most cases], the safety valve opens and excess steam escapes out (Fig. 3.4).
- The holding period is counted from this point of time, which is about 15 minutes in most cases.
- After the holding period, the electrical heater is stopped and the autoclave is allowed to cool till the pressure gauge indicates that the pressure inside is equal to the atmospheric pressure.
- The discharge tap is opened slowly and air is allowed to enter the autoclave. The lid is now opened and the sterilized materials are removed.

Sterilization Conditions

Autoclave can be set to provide higher temperatures by adjusting the pressure provided to the vessel.

- 121°C for 15 minutes at pressure of 15 pounds (lbs) per square inch (psi): This is the most commonly used sterilziation condition for autoclave.
- 126°C for 10 minutes at pressure of 20 psi
- 133°C for 3 minutes at pressure of 30 psi

Uses of Autoclave

Autoclave is particularly useful for media containing water that cannot be sterilized by dry heat. It is the method of choice for sterilizing the following:

- Surgical instruments
- Culture media
- Autoclavable plastic containers
- Plastic tubes and pipette tips
- Solutions and water
- Biohazardous waste
- Glassware (autoclave resistible)

Precautions

The following precautions should be taken while using an autoclave.

- Autoclave should not be used for sterilizing waterproof materials, such as oil and grease or dry materials, such as glove powder.
- Materials are loaded in, such a way that it allows efficient steam penetration (do not overfill the chamber).
- Material should not touch the sides or top of the chamber.
- The clean items and the wastes should be autoclaved separately.
- Polyethylene trays should not be used as they may melt and cause damage to the autoclave.

Types of Autoclaves

There are different types of autoclaves are available.

- Gravity displacement type autoclave: It is the most common type used in laboratories. They are available in various sizes and dimensions.
  - Vertical type (small volume capacity) (Fig. 3.5)
  - Horizontal autoclave (large volume capacity) (Fig. 3.4)
- Positive pressure displacement type autoclave
- Negative pressure (vacuum) displacement type.

Sterilization control

The effectiveness of the sterilization done by autoclave can be monitored by:

- **Biological indicator:** Spores of *Geobacillus stearothermophilus* (formerly called *Bacillus stearothermophilus*) are the best indicator, because they are resistant to steaming. Their spores are killed in 12 minutes at 121°C.
- Other indicators (as described for hot air oven) such as: Browne's tube, and thermocouple.
- Autoclave tapes.

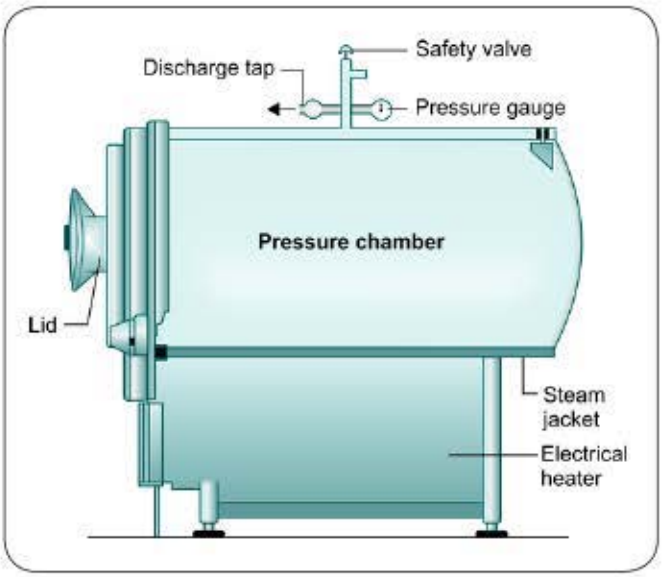

Fig. 3.4: Schematic diagram of horizontal autoclave

Fig. 3.5: Vertical autoclave

Filtration

Filtration is an excellent way to remove the microbial population in solutions of heat-labile materials like vaccine, antibiotics, toxin, serum and sugar solution as well as for purification of air.

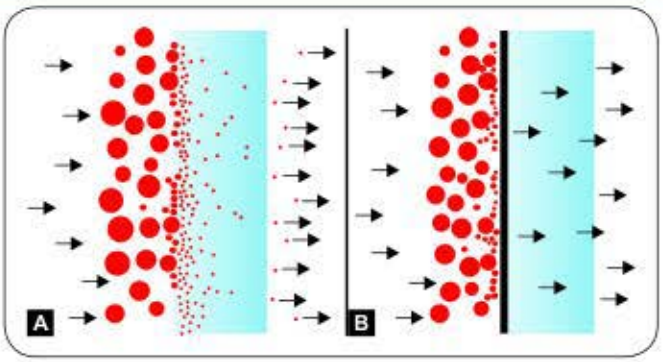
Types of Filters

There are two types of filters; depth and membrane filters.

Depth Filters

They are porous filters that retain particles throughout the depth of the filter, rather than just on the surface (Fig. 3.6A).

- Depth filters are composed of random mats of metallic, polymeric, or inorganic materials.
- These filters rely on the density and thickness of the filter to trap particles rather than the pore size.
- The advantages are—(1) they can retain a large mass of particles before becoming clogged, (2) flow rate of the fluid is high, (3) low cost
- Depth filters are commonly used when the fluid to be filtered contains a high load of particles, e.g. industrial applications, such as filtration of food, beverages and chemicals.
- **Disadvantages:** As some of the particles still come out in the filtrate; hence they are not suitable for filtration of solution containing bacteria. Some of the depth filters were used in the past for bacterial purification, such as:
  - Candle filters made up of diatomaceous earth (Berkefeld filters), unglazed porcelain (Chamberland filters)
  - Asbestos filters (Seitz and Sterimat filters)
  - Sintered glass filters.



Figs 3.6A and B: Filtration methods. **A.** Depth filters; **B.** Membrane filters

Membrane Filters

They are the most widely used filters for bacterial filtration. They are porous; retain all the particles on the surface that are larger than their pore size (Fig. 3.6B).

- Membrane filters are made up of cellulose acetate, cellulose nitrate, polycarbonate, polyvinylidene fluoride, or other synthetic materials.
- Pore size: Most commonly used membrane filters have an average pore diameter of 0.22 µm which removes most of the bacteria; allowing the viruses to pass through. While, filters of 0.45 µm are used to retain coliform bacteria in water microbiology and of 0.8 µm filters are used to remove airborne microorganisms in clean rooms and for the production of bacteria free gases.

Filtration of Liquid

Filtration of the liquid solution is done for the following purposes:

- To sterilize sera, sugar and antibiotic solutions.
- Separation of toxins and bacteriophages from bacteria.
- To obtain bacteria free filtrates of clinical samples for virus isolation.
- Purification of water—when water samples pass through filter discs, retain the organisms which can then be cultured, e.g. testin0g of water samples for *Vibrio cholerae* or typhoid bacilli.

Filtration of Air

Air filters are used to deliver bacteria-free air. Air can be filtered by various methods:

- Surgical masks (that allow air in but keep microorganisms out) are the simplest examples.
- There are two important air filters that are used in biological safety cabinets and laminar airflow systems):
  - **HEPA filters** (High-efficiency particulate air filters): HEPA filter removes 99.97% of particles that have a size of 0.3 µm or more.

- **ULPA filters** (Ultra-low particulate/penetration air): An ULPA filter can remove from the air at least 99.999% of dust, pollen, mold, bacteria and any airborne particles with a size of 0.12 µm or larger.

Sterilization Control

The sterilization control of membrane filters includes *Brevundimonas diminuta* and *Serratia marcescens*.

Radiation

Two types of radiations are available; ionizing and non-ionizing.

Ionizing Radiation

Ionising radiations include, X-rays, gamma rays (from Cobalt 60 source), and cosmic rays.

- **Mechanism:** It causes breakage of DNA without temperature rise (hence this method is also called as **cold sterilization**).
  - Ionizing radiation is an excellent agent for sterilization/disinfection. It penetrates deep into the object.
  - It destroys bacterial endospores and vegetative cells, both eukaryotic and prokaryotic; but not always effective against viruses.
- **Uses:** Gamma radiation is used in the sterilization/disinfection of—
  - Disposable plastic supplies, such as disposable rubber or plastic syringes, infusion sets and catheters.
  - Catgut sutures, bone and tissue grafts and adhesive dressings as well as antibiotics and hormones.
  - Irradiation of food (permitted in some countries)
- **Advantages** of ionizing radiation—(1) high penetrating power, (2) rapidity of action, and (3) temperature is not raised
- **Sterilization/disinfection control:** Efficacy of ionising radiation is tested by using *Bacillus pumilus*.

Non-ionizing Radiation

Examples of non-ionizing radiation include infrared and ultraviolet radiations.

- They are quite lethal but do not penetrate glass, dirt films, water; hence their use is restricted.
- The recommended dose is 250–300 nm wavelength, given for 30 minutes
- It is used for disinfection of clean surfaces in operation theaters, laminar flow hoods as well as for water treatment.
- Because UV radiation burns the skin and damages eyes, hence the area should be closed and UV lamps must be switched off immediately after use.

Ultrasound (Ultrasonic) Waves

High-frequency ultrasonic and sonic sound waves disrupt bacterial cells; but this method is not reliable, hence is not used now a days.

CHEMICAL AGENTS OF STERILIZATION/DISINFECTION

Though commonly called disinfectants, the chemical agents, based on the microbicidal ability are classified into four groups—chemical sterilant, low level, intermediate level and high level disinfectants (Table 3.2).

Antiseptics: They are the low to intermediate level disinfectants that are less toxic to the body surfaces; hence can be applied to skin, open wounds and mucosa.

The various groups of disinfectants discussed are as follows.

Alcohols

They are among the most widely used disinfectants and antiseptics.

- They are bactericidal and fungicidal but not sporicidal; some enveloped viruses (e.g. HIV) are also destroyed.
- **Examples:** The most popular alcohol germicides are ethanol and isopropanol, both are used in 70–80% concentration.
- They act by denaturing proteins and possibly by dissolving membrane lipids.
- Ethyl alcohol is used as surgical spirit (70%) in hand rubs as antiseptics.

TABLE 3.2: Classification of chemical disinfectants

Level of disinfectant	Bacterial spores	Tubercle bacilli	Nonenveloped viruses	Fungi	Enveloped viruses	Vegetative bacteria
Low-level disinfectant	No	No	No	+/–	Yes	Yes
Intermediate-level disinfectant	No	Yes	Yes	Yes	Yes	Yes
High-level disinfectant	May be	Yes	Yes	Yes	Yes	Yes
Chemical sterilant	Yes	Yes	Yes	Yes	Yes	Yes

- Isopropyl alcohol: Clinical thermometers and small instruments are disinfected by soaking in isopropyl alcohol for 10–15 minutes.

Aldehydes

Formaldehyde, glutaraldehyde and ortho-phthalaldehyde are the commonly used aldehydes. They combine with nucleic acids, proteins and inactivate them, probably by cross linking and alkylating the molecules. They are sporicidal and can be used as chemical sterilants.

- **Formaldehyde:** It is usually dissolved in water or alcohol before use. The formalin or formol (40% formaldehyde) is the most widely used preparation available commercially.
  - It is best used for—(1) preservation of anatomical specimen, (2) formaldehyde gas is used for fumigation of closed areas, such as operation theatres, (3) preparation of toxoid from toxin
  - Formaldehyde is toxic and irritant when inhaled, as well as it is corrosive to the metals.
- **Glutaraldehyde:** It is less toxic, less irritant and less corrosive; hence is best used to sterilize hospital and laboratory equipments, such as endoscopes and cystoscopes.
  - It is used as 2% concentration (2% Cidex). It usually disinfects objects within 20 minutes but may require as long as 12 hours to kill spores.
  - It is available in inactive form; has to be activated by alkalinization before use. Once activated, it remains active only for 14 days.
- **Ortho-phthalaldehyde** (0.55%) solution: This also be used for sterilization of endoscopes and cystoscopes and has many advantages over glutaraldehyde—(1) it does not require activation, (2) low vapour property, (3) better odor, (4) more stable during storage, (5) ↑mycobactericidal activity.

Phenolic Compounds

Phenol (carbolic acid) was the first widely used antiseptic and disinfectant; was introduced in surgery in 1867 by Joseph Lister (the father of antiseptic surgery).

- The phenol and its derivatives (called phenolics) are produced by distillation of coal tar between temperatures of 170°C and 270°C.
- **Mechanisms:** Phenolics act by denaturing proteins and disrupting cell membranes.
- **Advantages:** They have tuberculocidal activity, some are effective in the presence of organic materials.

Phenolics as Disinfectants

Cresol, xylenol, Lysol and ortho-phenylphenol are the common phenolics used in laboratories and hospitals as disinfectants.

- Lysol is a commercial preparation made of a mixture of phenolics.
- All the above phenolics have the ability to retain activity in presence of organic matter.
- However they are toxic and irritant to skin, hence they are only used as disinfectants but not as antiseptics.

Phenolics as Antiseptics

Certain phenolics are less irritant to skin, persist in skin for longer period and are widely used as antiseptics. In general, they are more active against gram-positive than gram-negative bacteria.

- Chlorhexidine: It is an active ingredient of savlon (chlorhexidine and cetrimide).
- Chloroxylenol: It is the active ingredient of dettol.
- Hexachlorophene: As it can cause brain damage, hence its use as antiseptic is restricted. It is indicated only in response to a staphylococcal outbreak.

Halogens

Among the halogens, iodine and chlorine have antimicrobial activity. They exist in free state, and form salt with sodium and most other metals.

Iodine

It is used as a skin antiseptic and kills microorganisms by oxidizing cell constituents and iodinating cell proteins. At higher concentrations, it may even kill some spores.

- **Tincture of iodine:** It is a preparation of iodine (2%) in a water-ethanol solution of potassium iodide. Although it is an effective antiseptic, but can cause skin allergy and a yellow stain is left.
- **Iodophor:** It is prepared by complexing iodine with an organic carrier such as povidone (forming povidone-iodine). It is water soluble, stable, and non-staining, and releases iodine slowly to minimize skin burns and irritation. They are used as preoperative antiseptics as well as disinfectants in laboratories. Some popular brands available are Wescodyne and Betadine.

Chlorine

It is the most commonly available disinfectant. It is used—(1) for municipal water supplies and swimming pools and is also employed in the dairy and food industries, (2) as laboratory disinfectant, (3) as bleaching agent—to remove the stain from clothes. Common uses of chlorine are given in Table 3.3.

- **Preparations:** It may be available as—(1) chlorine gas, (2) sodium hypochlorite (household bleach, 5.25%), or (3) calcium hypochlorite (bleaching powder).
- **Mechanisms:** All preparations yield hypochlorous acid (HClO), which causes oxidation of cellular materials and destruction of vegetative bacteria and fungi, but not spores.

TABLE 3.3: Common uses of chlorine with their mechanism of action

Common actions	Used in places	Property responsible
Bleaching	Laundry and home	Oxidation
Disinfection	Hospitals	Coagulation
Odor control	Toilets	Precipitation
Chlorination of drinking and process water	Water tanks	Septication
Elimination of slime and algae	Swimming pool and boiler water	pH adjustment

- **Disadvantages:** (1) Organic matter interferes with its action, hence excess chlorine always is added to water to ensure microbial destruction, (2) Carcinogenic-chlorine reacts with organic compounds to form carcinogenic trihalomethanes, (3) Daily preparation—sodium hypochlorite is unstable, disintegrates and the chlorine evaporates on exposure to sun light or air. Hence, it has to be prepared daily and should be kept away from sun light and air, (4) They are not active against *Giardia* and *Cryptosporidium*, (5) Sodium hypochlorite is corrosive and should be handled cautiously.

Oxidizing Agents

Hydrogen Peroxide (H_2O_2)

It is a strong oxidizer; is used as high level disinfectant as well as chemical sterilant.

- **Mode of action:** It breaks of H_2O_2, liberates toxic free hydroxyl radicals which are the active ingredients, attack membrane, lipid, DNA, and other cellular components.
- **Concentration:** H_2O_2 is effective against most organisms at concentration of 3–6%, while catalase producing organisms and spores require higher concentration (10%) of H_2O_2.
- **Use:** H_2O_2 is used to disinfect ventilator, soft contact lenses, and tonometer biprisms. Vaporized H_2O_2 is used for plasma sterilization (see highlight box below).
- **Advantage:** (1) H_2O_2 does not coagulate blood or does not fix tissues to surfaces, and in fact, it may enhance removal of organic matter from equipments (2) it is less toxic to man, (3) it is environmentally safe, (4) it is neither carcinogenic nor mutagenic.

Peracetic Acid

It is another recently described powerful oxidizing agent, even more active than H_2O_2. Concentrations of less than 1% are sporicidal even at low temperature.

- Use: It is a high level disinfectant and chemical sterilant; often used in conjunction with H_2O_2, to disinfect hemodialyzers and is also used in plasma sterilization (see below). It is also used for sterilizing endoscopes.
- However, peracetic acid may corrode steel, iron, copper, brass and bronze.

Plasma Sterilization

Plasma sterilization is a recently introduced sterilization method; increasingly used now a days.

- **Principle:** Plasma refers to a gaseous state consisting of ions, photons and free electrons and neutral uncharged particles (such as O and OH). These active agents present in plasma such as photons of ultraviolet rays and radicals (e.g. O and OH) are capable of killing microorganisms and spores efficiently.
- **Plasma sterilizers:** It is a special device use to create the plasma state (commercial brands, such as Sterrad and Plazlyte). They maintain a uniform vacuum inside the chamber.
- Chemical sterilants, such as H_2O_2 alone or a mixture of H_2O_2 and peracetic acid are used which provide O and OH.
- Low temperature is maintained (<50°C) throughout the process which preserves the integrity of heat labile items.
- It is used for sterilization of surgical instruments.
- **Sterilization control:** Efficacy of plasma sterilization is tested by using *Bacillus stearothermophilus*, *Bacillus subtilis* subsp. *niger*.

Heavy Metal Salts

Salts of heavy metals, such as **mercury, silver, arsenic, zinc** and **copper** were widely used in the past as germicides, but recently these have been superseded by other less toxic and more effective germicides. However, some of the metallic salts are still in use for examples:

- Silver sulfadiazine is used on burns surfaces.
- Silver nitrate (1%) solution is often added to the eyes of infants to prevent ophthalmia neonatorum. It is now replaced by erythromycin in many hospitals.
- Copper sulphate is an effective fungicide (algicide) in lakes and swimming pools.
- Mercury salts, such as mercuric chloride, thiomersal and mercurochrome were known antiseptics and antifungal agents, but are not used now days. However, thiomersal (merthiolate) is used as preservative in vaccines, sera and other immunoglobulin preparations.
- **Mechanism of action:** Heavy metals combine with bacterial cell proteins, often with their sulfhydryl groups, and inactivate them. They are more bacteriostatic than bactericidal.

Surface Active Agents

Surfactants (or surface active agents) are the compounds that lower the surface tension (or interfacial tension) between two liquids or between a liquid and a solid.

Surfactants may act as detergents, wetting agents, and emulsifiers. Because of their amphipathic nature (i.e. they have both polar hydrophilic and nonpolar hydrophobic ends), the detergents solubilize otherwise insoluble residues and are very effective cleansing agents. They are classified into anionic, cationic, nonionic and amphoteric compounds, of which the cationic detergents are effective disinfectants.

- **Cationic surfactants:** Quaternary ammonium compounds are the most popular cationic disinfectants in use.
  - Quaternary ammonium compounds have a positively charged quaternary nitrogen and a long hydrophobic aliphatic chain.
  - They disrupt microbial membranes and may also denature proteins.
  - They kill most bacteria (gram-positives are better killed than gram-negatives) but not *M. tuberculosis* or spores.
  - They are stable, and nontoxic to skin, but are inactivated by acidic pH, organic matter, hard water and soap.
  - Cationic detergents are often used as disinfectants for food utensils and small instruments and as skin antiseptics.
  - Examples of quaternary ammonium compounds include:
    - Alkyl trimethyl ammonium salts
    - Acetyl trimethyl ammonium bromide (cetavlon or cetrimide)
    - Benzalkonium chloride
    - Cetylpyridinium chloride.
- **Anionic surfactants**, e.g. common soaps: They have strong detergent but weak antimicrobial properties. These agents are most active at acidic pH.
- **The amphoteric surfactants:** They possess detergent properties of anionic compounds and antimicrobial activity of cationic compounds. They are active over a wide range of pH but the activity is reduced in presence of organic matter. Examples include **Tego compounds** which are the commercial name of a series of disinfectants whose active ingredient is DDAG (dodecyl-di-aminoethyl-glycine). They are used as antiseptics in dental practice, but are known to cause allergic reactions.

Dyes

Aniline and acridine are the two groups of dyes that have been used extensively as skin and wound antiseptics.

Aniline Dyes

These include crystal violet, gentian violet, brilliant green and malachite green.

- They are more active against gram-positive bacteria than gram-negative bacteria and have no activity against *M. tuberculosis*.
- They are non-toxic and non-irritant to the tissues.
- Their activity is reduced in presence of organic material, such as pus.
- They interfere with the synthesis of peptidoglycan component of the cell wall.
- These dyes are used in the laboratory as selective agents in culture media (e.g. malachite green in Lowenstein–Jensen medium, which is a selective medium used for isolation of *Mycobacterium tuberculosis*)

Acridine Dyes

These include acriflavine, euflavine, proflavine and aminacrine.

- They are affected very little by the presence of organic material.
- They are also more active against gram-positive bacteria than gram-negative bacteria but are not as selective as the aniline dyes.
- They interfere with the synthesis of nucleic acids and proteins in bacterial cells.

Gaseous Sterilization

Ethylene oxide (EtO)

Ethylene oxide (EtO) is one of the widely used gaseous chemical sterilants in present days.

- **Mechanism of action:** EtO has both microbicidal and sporicidal activity; acts by combining with cell proteins.
- **High penetration power:** The main advantage of EtO is, it rapidly penetrates packing materials, even plastic wraps.
- However, it is highly inflammable, irritant, explosive and carcinogenic. Hence, it is unsuitable for fumigation.
- A special equipment is used to carry out the sterilization, called ethylene oxide sterilizer (Fig. 3.7).
- As pure EtO is explosive, hence it is usually supplied in a 10–20% concentration mixed with inert gases like either CO_2 or dichloro-difluoro-methane.
- **Sterilization condition:** Three factors that influence the rate of sterilization are—EtO concentration, humidity, and temperature.
  - At EtO concentration of 700 mg/liter and 40– 50% relative humidity, sterilization is achieved in 5–8 hours at 38°C or 3–4 hours at 54°C.
  - Extensive aeration of the sterilized materials is necessary to remove residual EtO, because it is so toxic.
- **Sterilization control:** *Bacillus globigi* is used as biological indicator to check the effectiveness of sterilization.
- **Use:** Ethylene oxide is extensively used for sterilization of many heat sensitive items, such as disposable plastic Petri

Fig. 3.7: Ethylene oxide sterilizer

dishes and syringes, heart-lung machine components, sutures, catheters, respirators and dental equipments.

Low Temperature Steam Formaldehyde

This was widely used for fumigation of operation theaters, wards and laboratories. However, this method is no longer preferred, and is being replaced by modern methods of fumigation.

- Formaldehyde gas is generated by adding 150 g of KMnO4 to 280 mL formalin for every 1000 cu. feet of room volume.
- The room should be sealed for 48 hours.
- The gas is irritant and toxic when inhaled. Hence, after completion of disinfection, the effect of irritant vapors should be nullified by exposure to ammonia vapour.

Betapropiolactone (BPL)

BPL gas (0.2%) is active against all microorganisms including spores, however it has a low penetrating power and is carcinogenic, hence not used for fumigation. It is used for inactivation of vaccines.

Sporicidal Agents

Sporicidal agents are enlisted in Table 3.4.

TABLE 3.4: Sporicidal agents

▪ Ethylene oxide	▪ Peracetic acid
▪ Formaldehyde	▪ Autoclave
▪ Glutaraldehyde	▪ Hot air oven
▪ Hydrogen peroxide	▪ Plasma sterilization
▪ O-phthalic acid	

TABLE 3.5: Biological indicators of sterilization

Methods	Indicator
Hot air oven	*Clostridium tetani* non toxigenic strain, *B. subtilis* subsp. *niger*
Autoclave	*Bacillus stearothermophilus*
Filtration	*Brevundimonas diminuta* or *Serratia*
Ionizing radiation	*Bacillus pumilus*
Ethylene oxide	*Bacillus globigi*
Plasma sterilization	*Bacillus stearothermophilus* or *Bacillus subtilis* subsp. *niger*

Biological Indicators

Biological indicators used to assess effective sterilization by various methods are summarized in Table 3.5. If the sterilization process was appropriate, biological indicators should have been destroyed and should not grow if inoculated in appropriate culture media.

Common materials that need to be sterilized/disinfected and the commonly used methods to achieve the same in different clinical situations are enlisted in Table 3.6.

Comparison of range of activity against various microorganisms and level of disinfection that can be achieved by common chemical sterilants/disinfectants is given in Table 3.7

TESTING OF DISINFECTANTS

Phenol Coefficient (Rideal Walker) Test

Phenol coefficient is determined by the dilution of the disinfectant in question which sterilizes/disinfects the suspension of *Salmonella* Typhi in a given time divided by the dilution of phenol which sterilizes/disinfects the suspension in the same time.

- If the phenol coefficient is more than 1, the test disinfectant is said to be more effective than phenol.
- The drawbacks of Rideal Walker test are—(1) only the phenolic compounds can be assessed, (2) it does not assess the ability of the disinfectant to act in presence of organic matter.

Phenolic coefficient of a test disinfectant =

$$\frac{\text{Highest dilution of the test disinfectant that kills } S.\text{ Typhi in a given time}}{\text{Highest dilution of phenol that kills with this } S.\text{ Typhi in the same time}}$$

Chick Martin Test

It is a modification of Rideal and walker test, in which the disinfectants act in the presence of organic matter (e.g. dried yeast, feces, etc.) to simulate the natural conditions.

TABLE 3.6: Methods of sterilization/disinfection used in different clinical situations

Material	Method of sterilization/disinfection
Clinical thermometer	Isopropyl alcohol
Paraffin, glass syringe, flask, slide, oil, grease, fat, glycerol	Hot air oven
Operation theater, entryway, ward, lab fumigation , Preservation of anatomical specimen, woolen blanket	Formaldehyde gas > UV > BPL
Cystoscope, bronchoscope	Orthophthaldehyde > glutaraldehyde 2% (cidex)
Heart lung machine, respirator, dental equipments	Ethylene oxide
Vaccine, sera, antibiotic and sugar solution and body fluids	Filtration
Sharp instruments	Cresol
Milk	Pasteurization
Plastic syringe, catgut suture, swab, catheter, bone and tissue grafts, adhesive dressing	Ionizing radiation
Culture media, metal instruments, glassware and all suture materials except catgut	Autoclave
Metallic inoculation wire	Red hot by Bunsen burner
Infective material like soiled dressing, bedding, animal carcasses	Burning (incineration)
Metallic surgical instruments	Autoclave and infra-red radiation
Water	Chlorine as hypochlorite 0.2%
Skin	Tincture iodine, spirit (70% ethanol) and savlon
Contact lenses	H_2O_2 (hydrogen peroxide)

TABLE 3.7: Common disinfectants and their spectrum of action

Germicide and their concentrations	Level of disinfectant	Bacteria and enveloped viruses	Fungi	Un-enveloped viruses	*M. tuberculosis*	Spore	Inactivated by organic matter
Glutaraldehyde (2%)	High/CS	+	+	+	+	+	–
Formaldehyde (3–8%)	High/CS	+	+	+	+	+	–
H_2O_2 (3–25%)	High/CS	+	+	+	+	+	+/–
Chlorine (100–1000 ppm of free chlorine)	High	+	+	+	+	+/–	+
Isopropyl alcohol (60–95%)	Intermediate	+	+	+/-	+	–	+/–
Phenol (0.4–5%)	Intermediate	+	+	+/-	+	–	–
Iodophore (30–50 ppm of free iodine)	Intermediate	+	+	+	+/–	–	+
Quaternary ammonium compounds (0.4–1.6%)	Low	+	+/–	–	–	–	+

Abbreviations: CS, chemical sterilant; +, effectively kills; –, unable to kill; +/–, variably kills; ppm, parts per million

Capacity (Kelsey-Sykes) Test

It tests the capacity of a disinfectant to retain its activity when repeatedly used microbiologically (i.e. when the microbiological load keeps increasing).

In-use (Kelsey And Maurer) Test

It determines whether the chosen disinfectant is effective for actual use in hospital practice. The efficiency of a new disinfectant is determined by its ability to inactivate known number of standard strain pathogenic *Staphylococcus* on a given surface within a certain time.

SPAULDING'S CLASSIFICATION OF MEDICAL DEVICES

Earle H. Spaulding devised a rational approach to classify the patient-care items and equipments of a hospital into four categories (as critical, semi-critical, non-critical patient care items, and non-critical environmental surfaces) according to the degree of risk for infection involved in use of the items. This classification scheme is so clear and logical that it has been retained, refined, and successfully used by infection control professionals and others, while planning methods for disinfection or sterilization (Table 3.8).

TABLE 3.8: Spaulding's classification of medical devices

Medical device	Definition	Examples	Recommended sterilization/disinfection
Critical device	Enter a normally sterile site	Surgical instruments, cardiac and urinary catheters, implants, eye and dental instruments	Heat-based sterilization, chemical sterilant or high-level disinfectant
Semi-critical device	Comes in contact with mucus membranes or minor skin breaches	Respiratory therapy equipments, anesthesia equipments, endoscopes, laryngoscope, rectal/vaginal/esophageal probes	High-level disinfectant
Non-critical devices	Comes in contact with intact skin	BP cuff, ECG electrodes, bedpans, crutches, stethoscope, thermometer	Intermediate-level or low-level disinfectant
Non-critical environmental surfaces	Less direct contact with patient	Surfaces of medical equipments, examination table, computers	Low-level disinfectant

Abbreviations: BP, blood pressure; ECG, electrocardiograph

EXPECTED QUESTIONS

I. Essay:

1. Define sterilization and disinfection. Describe principle and uses of autoclave. Add a note on chemical sterilants.

II. Write short notes on:

1. Sterilization by dry heat
2. Pasteurization
3. Membrane filters
4. Gaseous sterilization
5. Testing of disinfectants

III. Multiple Choice Questions (MCQs):

1. Tyndallisation is a type of:
   a. Intermittent sterilization
   b. Boiling
   c. Pasteurization
   d. Dry heat

2. Browne's tube is used as indicator for efficacy of:
   a. Chemical sterilization
   b. Heat sterilization
   c. Filtration
   d. Ultraviolet rays

3. Which of the following is most resistant to sterilization?
   a. Tubercle bacilli
   b. Viruses
   c. Spores
   d. Prions

4. Endoscope is sterilized by:
   a. Glutaraldehyde
   b. Formaldehyde
   c. Autoclaving
   d. Hot air oven

5. Which is a form of cold sterilization?
   a. Infrared rays
   b. Steam sterilization
   c. Gamma rays
   d. UV rays

Answers

1. a **2.** b **3.** d **4.** a **5.** c

CHAPTER 4

Culture Media and Culture Methods

Chapter Preview

- Culture media
  - Constituents of culture media
  - Types of culture media
- Culture methods
  - Methods of culture
  - Anaerobic culture methods
- Preservation of microorganisms
- Methods of isolating bacteria in pure cultures

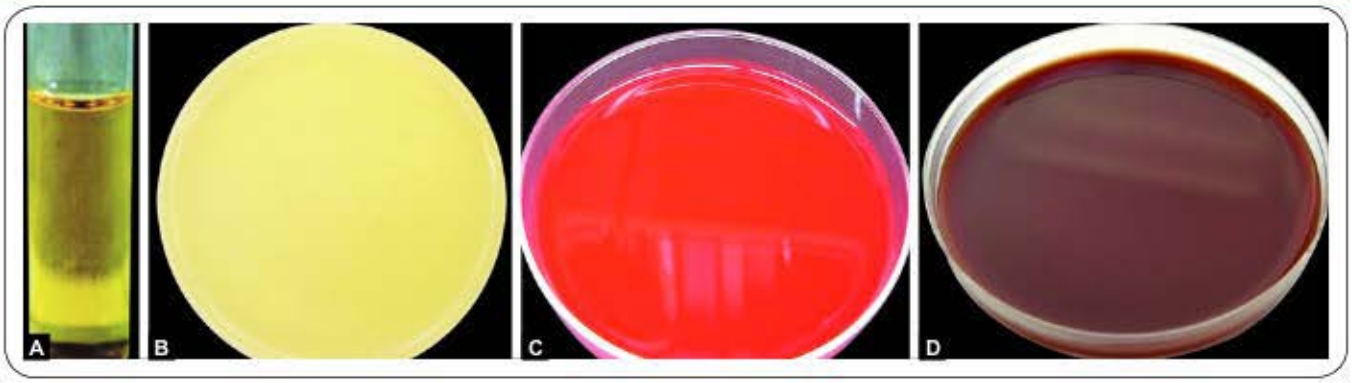
CULTURE MEDIA

Culture media are required to isolate the bacteria from the clinical specimens; following which the appropriate biochemical tests can be performed to identify the causative agent.

CONSTITUENTS OF CULTURE MEDIA

The basic constituents of culture media are:

- **Water:** Distilled water or potable water with low mineral content is suitable for culture media preparation. Water serves as the source of hydrogen and oxygen.
- **Electrolytes:** Sodium chloride or other electrolytes.
- **Peptone:** It is a complex mixture of partially digested proteins.
  - Source: It is obtained from lean meat or other protein material, such as heart muscle, casein or fibrin, or soya flour usually by digestion with proteolytic enzymes, such as pepsin.
  - Constituents: It contains proteoses, aminoacids, inorganic salts (phosphates, potassium and magnesium), accessory growth factors like nicotinic acid and riboflavin.
  - Special brands: Apart from standard grades of bacteriological peptones, some manufacturers supply special grades of peptones which are used for special purposes, e.g. neopeptone, proteose peptone, mycological peptone, etc.
- **Agar:** It is used for solidifying the culture media. It is commercially available in powder form; melts in water after boiling and jellifies after cooling.
  - Agar, also called 'agar-agar' is prepared from the cell wall of variety of seaweeds (red algae of species *Gelidium* and *Gracilaria*).
  - **Components:** It contains mainly cell wall derived long-chain polysaccharide (D-galctopyranose units) and a small amount of protein-like material, long chain fatty acids and traces of inorganic salts, such as calcium and magnesium.
  - **Agar is preferred over gelatine for solidification:** Agar is bacteriologically inert, it melts at 98°C and usually solidifies at 42°C. Agar does not add any nutritive property to the culture medium. Whereas gelatin is liquefied by a number of bacteria, it melts at 24°C, and remains in liquid state at room temperature.
  - **Concentration of agar** used depends on the manufacturer instructions and the purpose for which it is used.
    - For solid agar preparation: It is used in concentration of 1–2% (Japanese agar 2% or New Zealand agar 1.2%)
    - For semisolid agar–0.5%
    - For solid agar to inhibit *Proteus* swarming–6%.
  - **Preparation of agar media:** The appropriate amount of agar powder is added to water and the mixture is dissolved and then sterilized by placing it in an autoclave. When the temperature of the molten agar comes down to 45°C, it is poured to the Petri dishes and then allowed to set for 20 minutes.
- **Meat extract:** It is a commercial preparation (Lab-Lemco, Oxoid) of highly concentrated meat stock, usually made from beef. It contains protein degradation products, inorganic salts, carbohydrates and growth factors.
- **Yeast extract:** It is prepared commercially from washed cells of Baker's yeast. It contains aminoacids, inorganic salts (potassium and phosphates) and carbohydrates.



Figs 4.1A to D: **A.** Peptone water; **B.** Nutrient agar; **C.** Blood agar; **D.** Chocolate agar

- **Malt extract:** It consists of maltose (about 50%), starch, dextrin, glucose and 5% protein products.
- **Blood and serum:** They are important components of enriched media and provide extra nutrition to fastidious bacteria.
  - Usually 5–10% of sheep blood is used. Horse, ox or human blood can also be used.
  - Blood should be collected aseptically and rendered noncoagulable by defibrillation (by shaking the blood in a bottle containing sterile glass beads) or adding oxalate or citrate.
  - Serum is sterilized by filtration after collection.

TYPES OF CULTURE MEDIA

Bacteriological culture media can be classified in two ways.

A. Based on consistency, culture media are grouped into:

1. Liquid media (or broth)
2. Semisolid media
3. Solid media

B. Based on the growth requirements, culture media are classified as:

1. **Routine laboratory media:** They are prepared from nutrients, such as aqueous extract of meat, peptone, etc. They can further be classified into various types based on functional use or application, as follows—
   - Simple/basal media
   - Enriched media
   - Enrichment broth
   - Selective media
   - Differential media
   - Transport media
   - Anaerobic media
2. **Defined or synthetic media:** They are prepared from pure chemical substances and the exact composition of the media is known.
   - Simple synthetic media
   - Complex synthetic media

Routine Laboratory Media

Simple/Basal Media

They contain minimum ingredients that support the growth of non-fastidious bacteria. Examples include—

- **Peptone water:** It contains peptone (1%) + NaCl (0.5%) + water (Fig. 4.1A)
- **Nutrient broth:** It is made up of peptone water + meat extract (1%). It is available in three forms: (1) meat extract, (2) meat infusion, (3) meat digest broth.
- **Nutrient agar:** It is made up of nutrient broth + 2% agar (Fig. 4.1B).
- **Semisolid medium:** It is prepared by reducing the concentration of agar to 0.2 to 0.5 %.

Uses of Basal Media

The basal media are used for:

- Testing the non-fastidiousness of bacteria
- They serve as the base for the preparation of many other media.
- Nutrient broth is used for studying the bacterial growth curve
- Nutrient agar is the preferred medium for—
  - Performing the biochemical tests, such as oxidase, catalase and slide agglutination test, etc.
  - To study the colony morphology
  - Pigment demonstration
- Semisolid medium is used for—(1) demonstrating motility of the bacteria; motile bacteria spread throughout the semisolid medium, making the medium hazy, (2) maintaining stock culture.

Enriched Media

When a basal medium is added with additional nutrients, such as blood, serum or egg, it is called enriched medium. In addition to non-fastidious organisms, they also support the growth of fastidious nutritionally exacting bacteria. Examples include:

- **Blood agar:** It is prepared by adding 5–10% of sheep blood to the molten nutrient agar at 45°C (Fig. 4.1C).

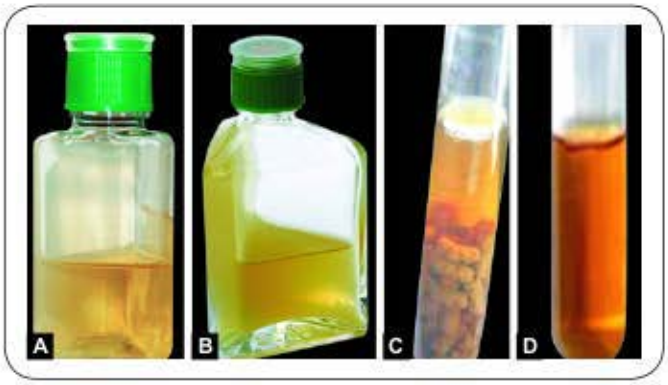
It is the most widely used medium in diagnostic bacteriology. Blood agar also tests the hemolytic property of the bacteria, which may be either—(1) partial or α (green) hemolysis and (2) complete or β hemolysis (described in detail in Chapter 5).

- **Chocolate agar:** It is the heated blood agar, prepared by adding 5–10% of sheep blood to the molten nutrient agar at 70°C, so that the RBCs will be lysed and the content of RBCs will be released, changing the color of the medium to brown (Fig. 4.1D). It is more nutritious than blood agar, and even supports certain highly fastidious bacteria, such as *Haemophilus influenzae* that does not grow on blood agar.
- **Loeffler's serum slope:** It contains serum. It is used for isolation of *Corynebacterium diphtheriae*.
- **Blood culture media:** They are also enriched media, used for isolating microorganisms from blood. They are either monophasic or biphasic media.
  - Monophasic medium: It contains brain-heart infusion (BHI) broth (Fig. 4.2A).
  - Biphasic medium: It has a liquid phase containing BHI broth and a solid agar slope made up of BHI agar (Fig. 4.2B).

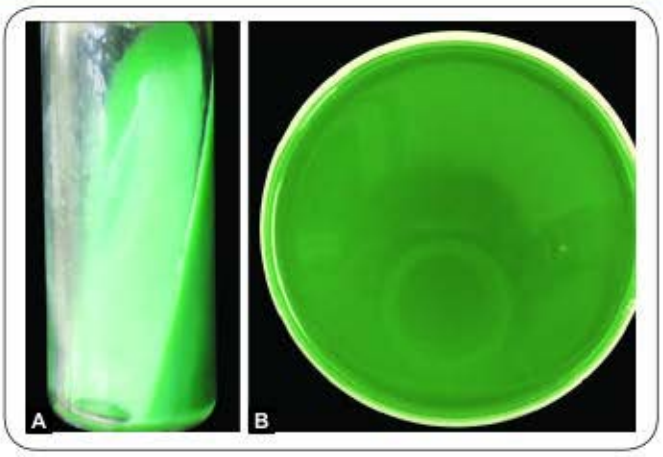
Enrichment Broth

They are the liquid media added with some inhibitory agents which selectively allow certain organism to grow and inhibit others. This is important for isolation of the pathogens from clinical specimens which also contain normal flora (e.g. stool and sputum specimen). Examples for enrichment broth include:

- Tetrathionate broth-used for *Salmonella* Typhi
- Gram-negative broth—used for isolation of *Shigella*
- Selenite F broth—used for isolation of *Shigella*
- Alkaline peptone water (APW)—used for *Vibrio cholerae*.



Figs 4.2A to D: A. Brain-heart infusion broth; **B.** Biphasic medium (Brain-heart infusion broth/Agar); **C.** Robertson's cooked meat medium; **D.** Thioglycollate broth



Figs 4.3A and B: A. Lowenstein–Jensen medium; **B.** TCBS agar

Selective Media

They are solid media containing inhibitory substances that inhibit the normal flora present in the specimen and allow the pathogens to grow.

- Lowenstein–Jensen (LJ) medium: It is used for isolation of *Mycobacterium tuberculosis* (Fig. 4.3A).
- Thiosulphate citrate bile salt sucrose (TCBS) agar: It is used for isolation of *Vibrio* species (Fig. 4.3B).
- DCA (deoxycholate citrate agar): It is used for the isolation of enteric pathogens, such as *Salmonella* and *Shigella* from stool (Fig. 4.4A).
- XLD (xylose lysine deoxycholate) agar: It is also used for same purpose as that DCA. (Fig. 4.4B).
- Potassium tellurite agar (PTA): It is is used for isolation of *Corynebacterium diphtheriae*.
- Wilson Blair bismuth sulfite medium: It is used for isolation of *Salmonella* Typhi.

Transport Media

They are used for the transport of the clinical specimens suspected to contain delicate organism or when the delay is expected while transporting the specimens from the site of collection to the laboratory (Table 4.1). Bacteria do not multiply in the transport media, they only remain viable.

TABLE 4.1: Transport media used for common bacteria

Organism	Transport media
Streptococcus	Pike's medium
Neisseria	Amies medium and Stuart's medium
Vibrio cholerae	▪ VR (Venkatraman-Ramakrishnan) medium ▪ Autoclaved sea water ▪ Cary Blair medium
Shigella, Salmonella	▪ Buffered glycerol saline ▪ Cary Blair medium

Differential Media

These media differentiate between two groups of bacteria by using an indicator, which changes the color of the colonies of a particular group of bacteria but not the other group.

- **MacConkey agar:** It is a differential and low selective medium, commonly used for the isolation of enteric gram-negative bacteria (Fig. 4.4C).
  - It differentiates organisms into LF or lactose fermenters (produce pink colored colonies, e.g. *Escherichia coli*) and NLF or non-lactose fermenters (produce colorless colonies, e.g. *Shigella*).
  - **Composition:** It contains peptone, lactose, agar, neutral red (indicator) and taurocholate.
  - Most laboratories use combination of blood agar and MacConkey agar for routine bacterial culture.
- **CLED agar (cysteine lactose electrolyte-deficient agar):** This is another differential medium similar to MacConkey agar, capable of differentiating between LF and NLF. It is used as an alternative to combination of blood agar and MacConkey agar, for the processing of urine specimens (Fig. 4.3D).
  - Advantages over MacConkey agar: It is less inhibitory than MacConkey agar, supports the growth of gram-positive bacteria (except β hemolytic *Streptococcus*) and *Candida*.
  - Advantage over blood agar: It can prevent the swarming of *Proteus*.

Anaerobic Culture Media

Anaerobic media contain reducing substances which take-up oxygen and create lower redox potential and thus permit the growth of obligate anaerobes, such as *Clostridium*. Examples are as follows:

- **Robertson's cooked meat (RCM) broth:** It contains chopped meat particles (beef heart), which provide glutathione (a sulfhydryl group containing reducing substance) and unsaturated fatty acids. It is the most widely used anaerobic culture medium (Fig. 4.2C). It is also used for maintenance of stock cultures.
- **Other anaerobic media** include:
  - Thioglycollate broth (Fig. 4.2D)
  - Anaerobic blood agar
  - BHIS agar (Brain-heart infusion agar) with supplements (vitamin K and hemin)
  - Neomycin blood agar
  - Egg yolk agar
  - Phenyl ethyl agar
  - *Bacteroides* bile esculin agar (BBE agar)

Defined or Synthetic Media

Chemically defined media are used for various experimental purposes. They are prepared exclusively from pure chemical substances in such a way that their composition, i.e exact quantity of each chemical used is known.

Simple Synthetic Media

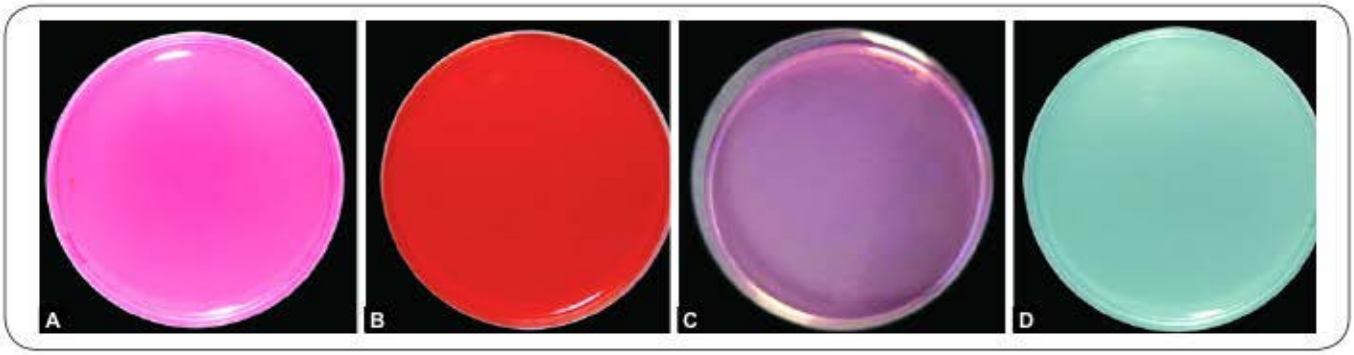
They contain a carbon and energy source, such as glucose, or lactose, and an inorganic source of nitrogen, usually in the form of ammonium chloride, phosphate or sulfate and various inorganic salts in a buffered aqueous solution. They provide the basic essentials for the growth of many non-fastidious heterotrophs, but they will not support the growth of fastidious bacteria.

Complex Synthetic Media

Here, in addition to the simple synthetic media certain aminoacids, purines, pyrimidines, and other growth factors are incorporated. Hence, they can also support the growth of more exacting bacteria.

CULTURE METHODS

The bacteriological culture is done in a laboratory, for the following purposes:



Figs 4.4A to D: **A.** DCA; **B.** XLD agar; **C.** MacConkey agar; **D.** CLED agar

- Isolating bacteria in pure culture from the clinical specimens
- To perform biochemical tests for the identification of bacteria
- To perform antimicrobial susceptibility testing of the isolated bacteria
- To maintain stock cultures
- To obtain sufficient growth for the preparation of antigens
- For typing of bacterial isolates
- To estimate the viable bacterial count

METHODS OF CULTURE

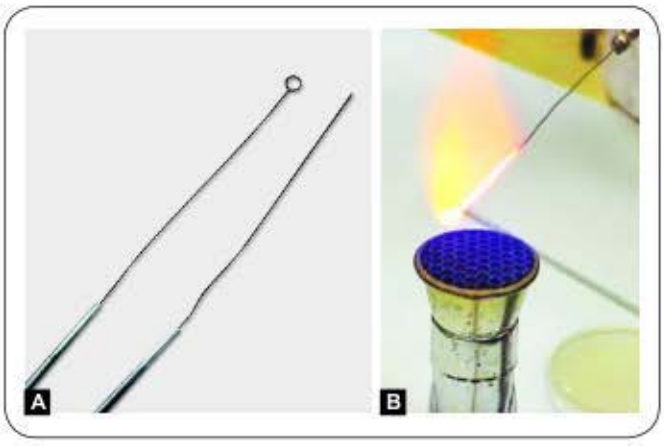
Loops and Straight Wires

Inoculation of specimen onto the culture media is carried out with the help of loops and straight wires made up of platinum or nichrome wire (Fig. 4.5A).

- **Bacteriological loops** of 2–4 mm internal diameter are used for streaking the culture plates.
- **Bacteriological straight wires:** They are used for making stroke culture and stab culture.
  (However, in lawn culture, wires are not used. Instead, sterile swab soaked in the broth culture of the bacteria is used).
- The inoculating straight wire or loop is first heated in the Bunsen flame by making it red hot (Fig. 4.5B) and then made cool waiting for 10 seconds.
- The entire process of bacteriological culture method should be carried out in biological safety cabinet to prevent laboratory acquired infections (Fig. 4.6).

Streak Culture

It is the routine method employed for isolation of bacteria from the clinical specimen or for obtaining individual isolated colonies from a mixed culture of bacteria.



Figs 4.5A and B: A. Bacteriological loop and straight wire; **B.** Flaming the loop (red hot)

Fig. 4.6: Biological safety cabinet

Method of streaking

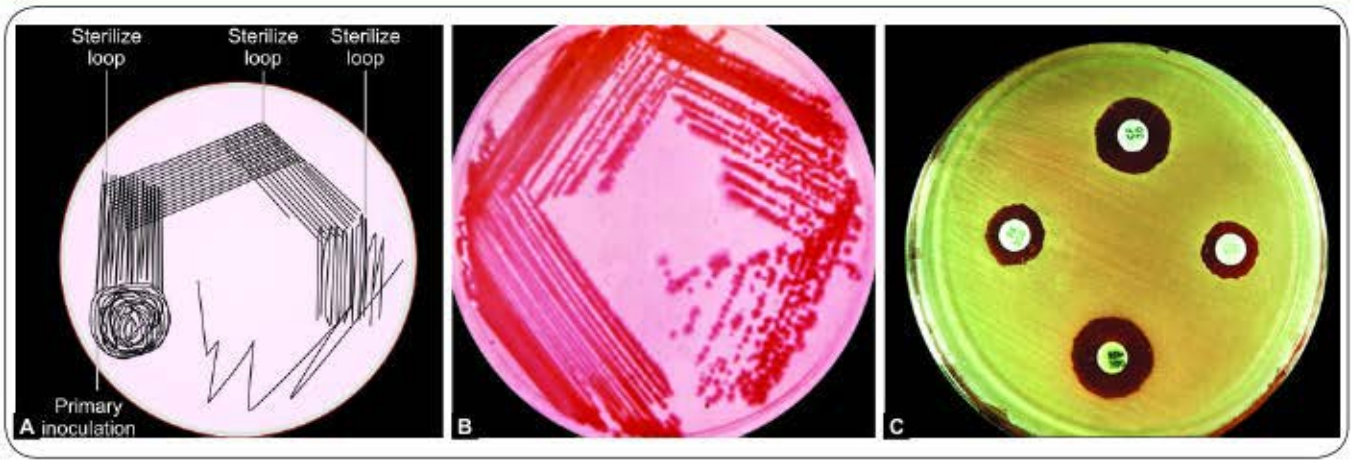
A loopful of specimen is smeared onto the surface of a dried solid culture plate near the peripheral area with the help of a sterile bacteriological loop to form the primary inoculum.

- From the primary inoculum, it is spread thinly over the culture plate by streaking with the loop in parallel lines to form the secondary, tertiary inoculum and finally a feathery tail end (Fig. 4.7A).
- Intermittent heating: The loop is flamed and cooled in between the different set of streaks to get isolated colonies.
- The culture plate is incubated at 37°C for 12–18 hours (overnight).
- Confluent growth occurs at the primary inoculum and well separated colonies are obtained on the final streaks (Fig. 4.7B).
- Obtaining isolated colonies is the prerequisite to perform various biochemical tests to confirm the identification of bacteria.

Lawn or Carpet Culture

Lawn culture provides uniformly thick surface growth of the bacterium on the solid medium (Fig. 4.7C). There are two methods of obtaining lawn cultures, which are as follows:

- Swabbing—A sterile swab soaked in liquid bacterial culture is inoculated on to the culture plate and then incubated at 37°C overnight to obtain uniform lawn of bacterial growth on the surface of the culture plate.



Figs 4.7A to C: A. Streak culture (schematic representation); **B.** Isolated colonies grown by following streak culture; **C.** Lawn culture of a bacterial isolate to perform the antimicrobial susceptibility testing

- Flooding-The surface of the culture plate is flooded with a liquid culture or suspension of the bacterium and then excess material is drained out.

Lawn culture is useful for:

- Carrying out antimicrobial susceptibility testing by disk diffusion method (Fig. 4.7C)
- Bacteriophage typing
- Producing large amount of bacterial growth required for preparation of bacterial antigens and vaccines.

Stroke Culture

This is carried out on agar slopes or slants by streaking the straight wire in a zigzag fashion (Fig. 4.8A).

- Stroke culture provides a pure growth of bacterium for carrying out diagnostic tests.
- Examples where stroke culture is used are citrate utilization test and urease test.

Stab Culture

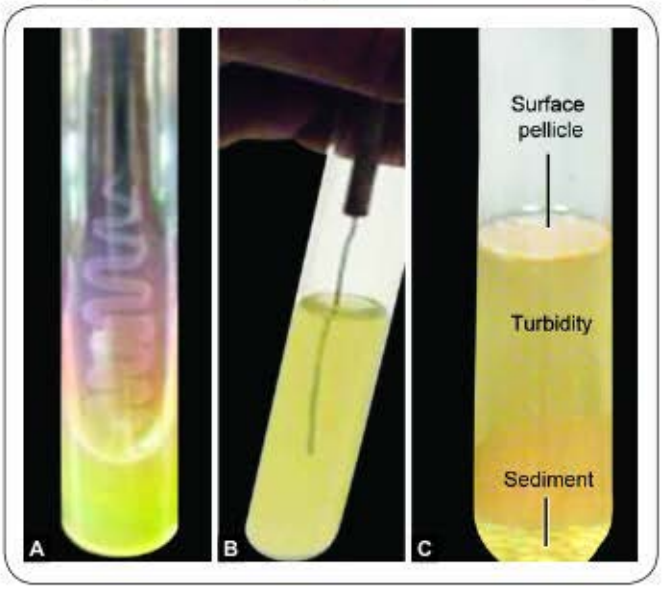
Stab culture is performed by stabbing the semisolid agar butt by a straight wire (Fig. 4.8B).

- Stab culture is used for—(1) maintaining stock cultures, (2) for demonstration of oxygen requirement of the bacteria by oxidative-fermentative (OF) test, (3) motility testing using semisolid agar.
- Examples where stab culture is used are mannitol motility medium, nutrient agar semisolid butts, triple sugar iron agar test or TSI (here both stroke and stab cultures are made).

Liquid Culture

Liquid cultures in test tubes, screw-capped bottles (e.g. McCartney bottle) or flasks may be inoculated by touching with a loop or by adding the inoculum with pipettes or syringes.

- **Bacterial growth** is detected by observing the turbidity in the medium—(1) some bacteria produce uniform turbidity, (2) some produce granular turbidity with sediment at the bottom of the tube, (3) some aerobic bacteria form surface pellicles (Fig. 4.8C).
- **Uses:** Liquid cultures are useful for (1) blood culture, (2) for sterility testing, (3) water analysis.
- **Advantages:** Liquid cultures are preferable for culture of—(1) specimen containing small quantity of bacteria, (2) specimens (e.g. blood) containing antibiotics and other antibacterial substances, as these inhibitory agents are neutralized by dilution in the medium. (3) It is also preferred when large yields of bacteria are required.



Figs 4.8A to C: A. Stroke culture; **B.** Stabbing with inoculation wire (stab culture); **C.** Liquid culture in test tube (turbidity indicates growth)

- **Disadvantages:** (1) Liquid cultures do not provide a pure culture from a mixed inoculum, (2) Identification of bacteria is not possible.

Pour-plate Culture

This is a quantitative culture method, used to estimate viable bacterial count.

Pour-plate Method

This is one of the best method to determine the number of bacteria present per mL of liquid broth/specimen.

- **Serial 10-fold dilutions** of the original bacterial suspension are made. This is achieved by:
  - 9 mL of nutrient broth is poured into a set of test tubes.
  - 1 mL of the bacterial suspension added to the first test tube, mixed and then 1 mL is serially transferred to the subsequent tube and so on.
- **Pour plating:** 1 mL from each tube is added to a measured quantity of molten nutrient agar (which has been cooled to 45°C), mixed properly, and then is poured into a Petri dish.
- After being cooled and solidified, the Petri dishes are incubated overnight at 37°C.
- **Colony counting:** Next day, the total number of colonies formed are counted from one among the plate that contains colonies between 50–500 colonies/plate. The lower dilutions will produce much crowded colonies, hence not suitable for counting. Each colony represents one bacterium in the specimen (Fig. 4.9).
- **Viable count/mL** of the specimen is calculated by multiplying the number of colonies/plate with the dilution factor.

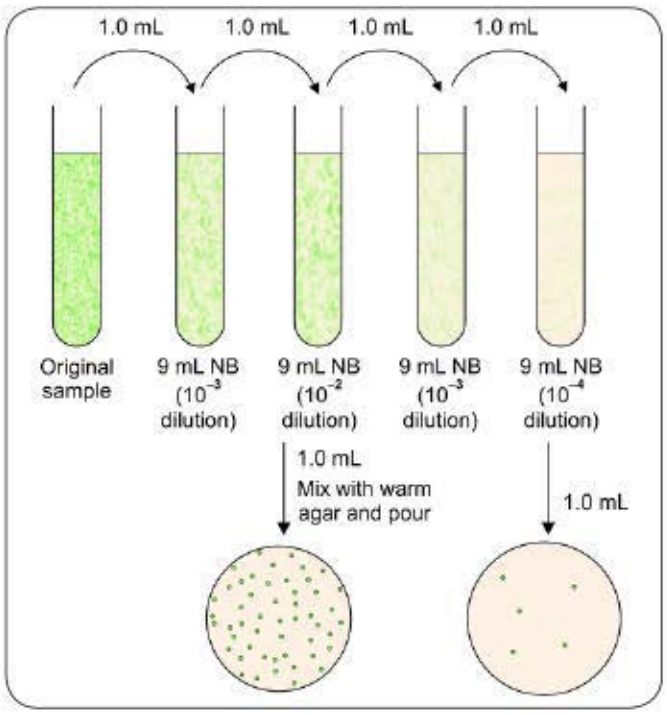


Fig. 4.9: Pour-plate method

Fig. 4.10: Bacteriological incubator

Spread-plate Method

This is another method for estimating the viable bacterial count. After serial dilution of the sample, known volume of individual dilutions are spread evenly on the surface of a suitable agar plate to obtain a lawn culture. After incubation, colonies are counted and multiplied by dilution factor to estimate the colony count.

Incubation of Culture Media

Most of the pathogenic organisms grow best at 37°C, i.e. body temperature of human beings. For aerobic bacteria, inoculated culture plates are incubated at 37°C for overnight in an incubator.

Bacteriological Incubator

It is a device used to grow and maintain bacteriological cultures or cell cultures (Fig. 4.10). The incubator maintains optimal temperature. Some incubators are specially designed to maintain other conditions, such as humidity and the carbon dioxide (CO_2).

Incubatory Conditions

There are various incubatory conditions required, depending up on the bacteria to be isolated.

- **Candle jar:** Inoculated media are placed in a jar with a lighted candle and then jar is sealed. The burning candle reduces oxygen to a point where the flame goes off (Fig. 4.11). This provides an atmosphere of approximately 3–5% CO_2. This is useful for capnophilic bacteria, such as *Brucella abortus, Streptococcus,* pneumococcus and gonococcus.

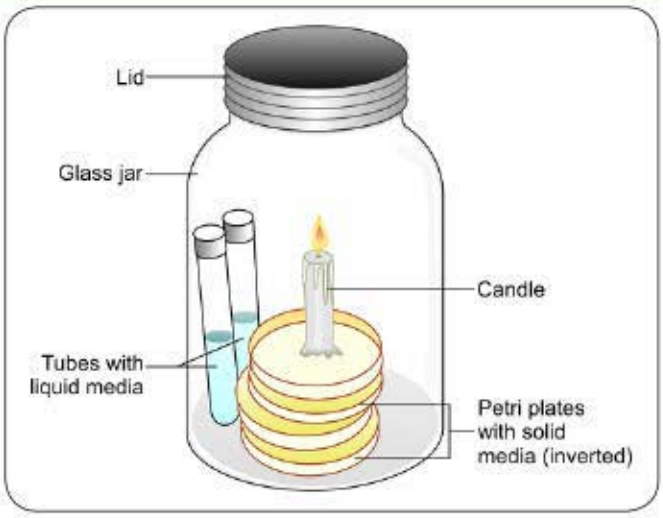

Fig. 4.11: Candle jar

- Microaerophilic bacteria, such as *Campylobacter* and *Helicobacter* require 5% oxygen for optimum growth.
- Anaerobic culture methods (see below).

ANAEROBIC CULTURE METHODS

Obligate anaerobic bacteria can grow only in the absence of oxygen, hence for the growth of such bacteria, anaerobic environment is needed. The following are the methods used to create anaerobiosis:

1. Production of Vacuum

This is achieved by incubating cultures in a vacuum desiccator. It is not an effective method, hence not used.

2. By Displacement and Combustion of Oxygen

This involves evacuation of the air from jar and replacement with inert gas like hydrogen followed by removal of the residual oxygen by use of a catalyst. It is carried out by:

- McIntosh and Filde's anaerobic jar (Fig. 4.12A)
- Anoxomat instrument (Fig. 4.12B)

McIntosh and Filde's Anaerobic Jar

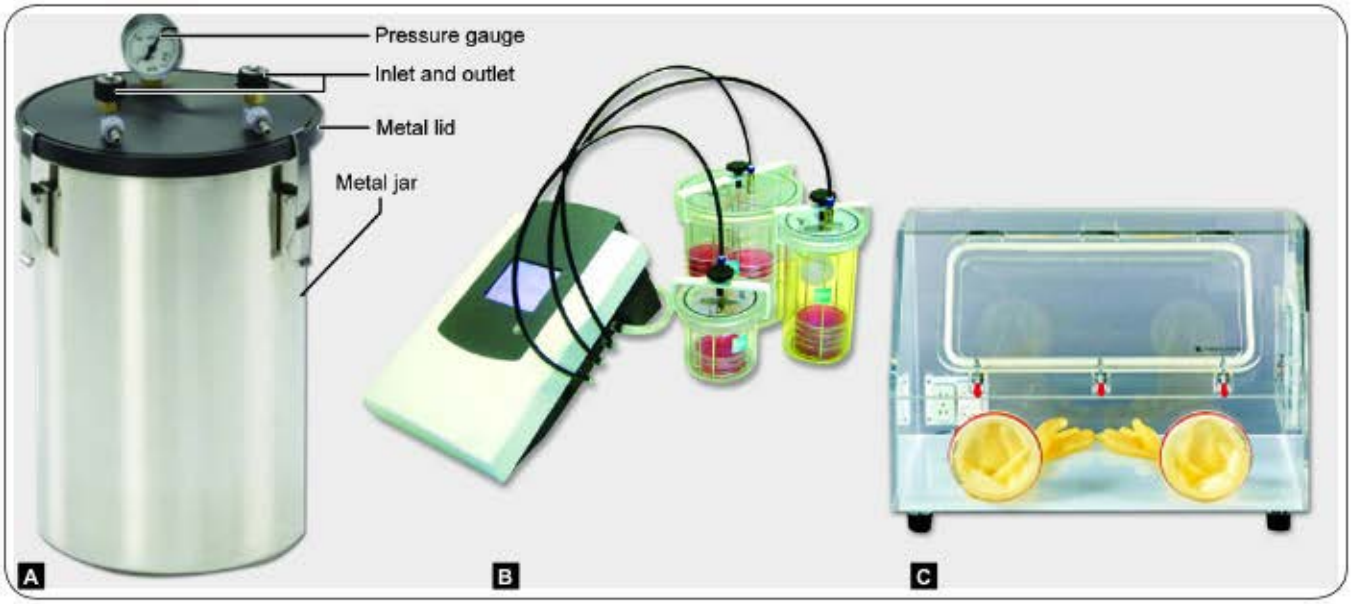
It is one of the most effective and popular method for creating anaerobiosis. It consists of a metal or glass jar with a metal lid, attached with a screw (to close airtight), pressure gauge and two openings (inlet and outlet).

- **Evacuation of air and replacement with hydrogen gas:** This is done manually, by using a Kipp's apparatus. Because this is a cumbersome procedure, hence this method is less commonly used now.
- **Removal of residual oxygen:** This is done by using a catalyst (sachet containing aluminium pellets coated with palladium) which is suspended from the inner side of the lid. It helps in removing the residual oxygen by combining with hydrogen to form water.

$$[O_2 + H_2 \xrightarrow{\text{Catalyst}} H_2O]$$

Anoxomat

This is an automated equipment (Fig. 4.12B) which evacuates the air from jar and replaces by hydrogen gas from a cylinder. The same catalyst is used here to remove the traces of oxygen. It is easier to operate than McIntosh jar method and claims to be highly effective for creating anaerobiosis.



Figs 4.12A to C: **A.** McIntosh and Filde's anaerobic jar; **B.** Anoxomat anaerobic system; **C.** Anaerobic glove box

3. Absorption of Oxygen by Chemical Methods

Principle

Instead of displacing the oxygen from the jar, the oxygen is removed by chemical reactions (e.g. alkaline pyrogallol) in contrast to evacuation and replacement technique used in McIntosh Filde's jar. This principle is used in GasPak system (BD diagnostics).

GasPak System

At present, it is the most commonly used method for anaerobiosis. It is very simple to perform and is perfect for a laboratory having less sample load.

- It uses a sachet containing sodium bicarbonate and sodium borohydride which react chemically in presence of water, to produce hydrogen and CO_2 gas (Fig. 4.13).
- The traces of oxygen is removed by using the same catalyst used for McIntosh Fildes method (aluminium pellets coated with palladium) placed below the jar (Fig. 4.13).
- **Indicator of anaerobiosis:** The effectiveness of anaerobiosis can be checked by the following methods:
  - Chemical indicator: Reduced methylene blue remains colorless in anaerobic conditions, but turns blue on exposure to oxygen.
  - Biological indicator: Plate inoculated with *Pseudomonas* is incubated along with other inoculated plates for anaerobic culture. Absence of growth of *Pseudomonas* (which is an obligate aerobe) indicates that perfect anaerobiosis has been achieved.

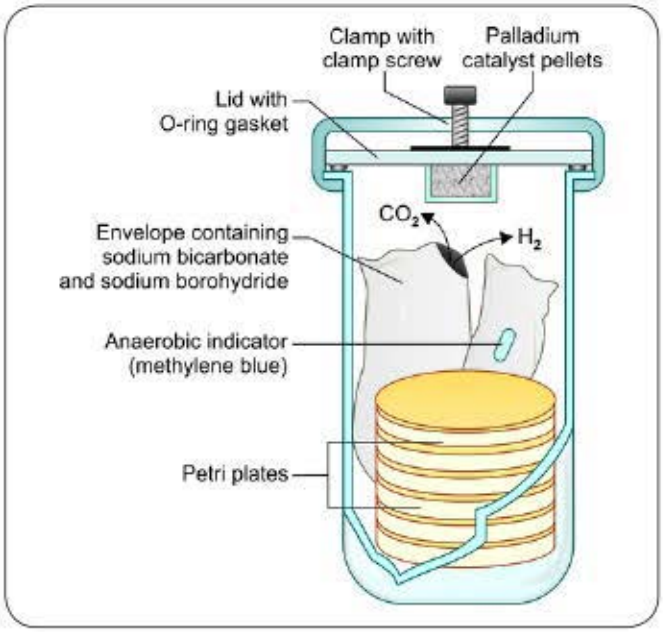


Fig. 4.13: Gas-pak anaerobic system

4. Anaerobic Glove Box (or Anaerobic Chamber)

It is a self-contained anaerobic system that allows microbiologists to process the specimen and perform most bacteriological techniques for isolation and identification of anaerobic bacteria without exposure to oxygen (Fig. 4.12C).

5. By Using Various Reducing Agents

Oxygen in culture media can be reduced by various reducing agents, such as glucose, thioglycollate, cooked meat pieces, cysteine and ascorbic acid. Robertson cooked meat broth is the most widely employed anaerobic culture medium which uses chopped meat particles (beef heart) as reducing agent.

6. Prereduced, Anaerobically Sterilized (PRAS)

PRAS media are prepared entirely under oxygen-free conditions from initial sterilization to packaging in sealed foil packets.

PRESERVATION OF MICROORGANISMS

Preservation of microorganisms has been a long tradition in microbiology. Preservation of organisms is necessary for epidemiological investigation, future research and educational purposes. Both short-term (weeks to months) and long-term (up to years) preservation methods are available.

Various methods of preservation of microorganisms are as follows:

Short-term Preservation Methods

Short term preservation methods are cheaper, easy to perform. However, the phenotypic and genotypic properties of bacteria may get altered as organism is more liable to undergo mutations.

Subculturing

Regular subculturing on to various media (e.g. semisolid butts or nutrient agar slopes) is the most common and routinely followed method for bacterial preservation. By this method cultures can be preserved for not more than a few weeks. Cooked-meat medium is used for the preservation of anaerobes.

Other Short-term Methods

- Preservation by immersing the culture in mineral oil, glycerol, or sterile distilled water
- Freezing at –20°C
- Drying: This may be useful for moulds and spore bearing bacteria.

Long-term Preservation Methods

These methods are used for preserving the microorganisms for several years. Though the equipment cost is high, these methods have several advantages—(1) cultures occupy less space, (2) phenotypic and genotypic characters are well maintained, (3) reduce chance of organism undergoing mutations, (4) viability is well maintained.

Long-term preservation methods are as follows:

Ultra Temperature Freezing

This involves mixing the cultures with cryopreservative agents, such as glycerol, skimmed milk, sucrose, etc and incubating at –70°C.

Lyophilization (Freeze-drying)

It is the most ideal method for successful storage of most bacteria.

- This process involves freezing of the liquid culture followed by dehydration to remove water from frozen bacterial suspensions.
- Lyophilization of bacterial cultures results in a stable, readily rehydrated product. Lyophilized cultures are best maintained at 4°C.

METHODS OF ISOLATING BACTERIA IN PURE CULTURES

Several methods are followed to obtain pure culture of individual bacterium from specimen containing mixture of bacteria:

- **Surface plating:** Streaking with intermittent heating is a routinely used method in the laboratory.
- **Selective media and enrichment broth:** It is employed for isolating pathogens from specimens containing normal flora, e.g. feces.
- **Pre-treatment of specimens:** Suitable bactericidal substances are used for pre-treatment of specimens to isolate a particular bacterium, e.g. concentration and decontamination of sputum sample with 4% NaOH before culturing it for *Mycobacterium tuberculosis*.
- **Anaerobiosis:** Obligate aerobes and anaerobes may be separated by incubating the plates under aerobic and anaerobic conditions.
- **Heating:** Mixture of bacteria in liquid medium with different optimum growth temperatures can be separated by heating the medium at different temperatures. For example, heating at 60°C would allow only the thermophilic bacteria to grow.
- **Filters:** Filters of different pore diameters are widely used for separating bacteria of different sizes and also for separating viruses from bacteria.
- **Based on motility:** Motile bacteria can be separated from non-motile bacteria by sub culturing them on to Craigie tube.
- **Animal inoculation:** Pathogenic bacteria can be separated from non-pathogenic bacteria by inoculating the mixture into susceptible animals followed by their isolation from the lesions which would be produced only by the pathogenic bacteria. For example, *Bacillus anthracis* can be separated from other aerobic spore bearing bacilli by inoculation into guinea pigs.

EXPECTED QUESTIONS

I. Write short notes on:

1. Enriched media
2. Selective media
3. Transport media
4. Anaerobic culture methods
5. Methods of isolating bacteria in pure culture

II. Multiple Choice Questions (MCQs):

1. Recommended transport medium for stool specimen suspected to contain *Vibrio cholerae* is:
   a. Buffered glycerol saline medium
   b. Venkatraman-Ramakrishnan medium
   c. Nutrient broth
   d. Blood agar

2. Which is an enriched media?
   a. Selenite F broth
   b. Peptone water
   c. MacConkey agar
   d. Chocolate agar

3. Agar concentration required to prepare nutrient agar is:
   a. 2%
   b. 6%
   c. 0.25%
   d. 0.5%

4. Robertson cooked meat broth is an example of:
   a. Enriched media
   b. Enrichment media
   c. Anaerobic media
   d. Nutrient media

Answers

1. b **2.** d **3.** a **4.** c

CHAPTER 5

Identification of Bacteria

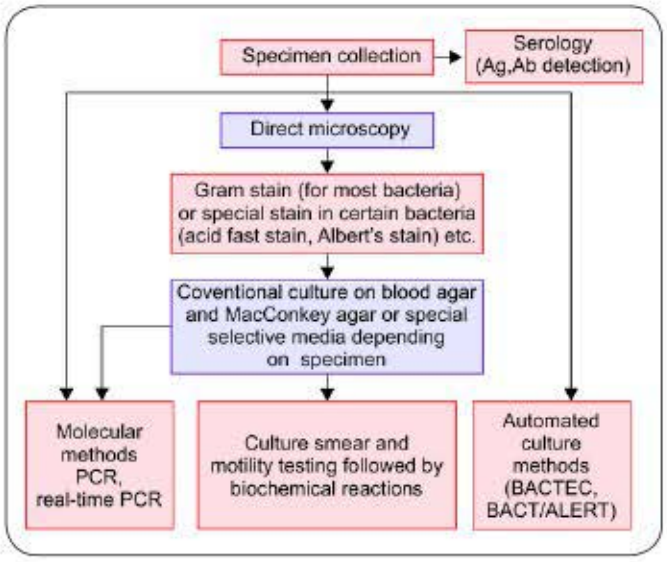
Chapter Preview

- Conventional method
- Automated culture techniques
- Molecular methods
  - Polymerase chain reaction (pcr)
  - Real-time pcr (rt-pcr)
- Microbial typing

Identification of bacteria can be done by various methods, such as (1) conventional methods of culture and identification, (2) automated culture techniques, and (3) molecular methods (Fig. 5.1).

CONVENTIONAL METHOD

Conventional method consists of specimens subjected to direct microscopy (Gram stain or any other special stain), followed by conventional culture on blood agar and MacConkey agar or any other special media. Colonies grown on culture media are subjected to culture smear and motility testing. Based on the culture smear report, the appropriate biochemical reactions are put for bacterial identification.



Specimen collection
Serology (Ag,Ab detection)
Direct microscopy
Gram stain (for most bacteria) or special stain in certain bacteria (acid fast stain, Albert's stain) etc.
Coventional culture on blood agar and MacConkey agar or special selective media depending on specimen
Molecular methods PCR, real-time PCR
Culture smear and motility testing followed by biochemical reactions
Automated culture methods (BACTEC, BACT/ALERT)

Fig. 5.1: Schematic representation of microbial identification

Specimen Collection

Specimen collection depends upon the type of underlying infections (Table 5.1). The proper collection of specimen is the key for correct and accurate identification of the bacteria. The following general principles should be followed while collecting the specimen:

- Standard precautions should be followed for collecting and handling all specimens. (Described in detail in Chapter 55).
- Whenever possible, culture specimens should be collected prior to administration of any antimicrobial agents.
- Contamination with indigenous flora should be avoided.
- Swabs are convenient but inferior to tissue,aspirate and body fluids.
- All specimens must be appropriately labelled.
- The specimens should be delivered to the laboratory as soon as possible after collection. If required appropriate transport media should be used.

TABLE 5.1: Type of infections and various specimens collected

Type of infections	Specimens collected
Wound and soft tissue infection	Pus or exudate, swabs, aspirates for abscess
Blood steam infections	Blood
Urinary tract infection	Midstream urine Suprapubic aspirated urine
Diarrheal diseases	Stool (mucus flakes), rectal swab
Respiratory tract infection	Sputum, throat swab, Bronchoalveolar lavage or endotracheal aspirate
Eye and ear infections	Conjunctival swabs, Corneal scrapings Swabs from outer ear/eye
Infections of the sterile area	Sterile body fluids; e.g. CSF, pleural fluid, synovial fluid ,peritoneal fluid, etc.

- Specimens should be collected in tightly sealed, leak proof containers.
- Specimens grossly contaminated or compromised may be rejected.
- If anaerobic culture is requested, proper anaerobic collection containers with media should be used.

Direct Microscopy

Direct smear examination—specimens are subjected to the following staining techniques.

- **Gram staining:** It is the first and foremost step done for bacterial identification. It divides bacteria into gram-positive and gram-negative.
- **Albert's staining:** It is employed to identify *Corynebacterium diphtheriae*, the causative agent of diphtheria.
- **Ziehl-Neelsen (ZN) acid fast staining:** It differentiates acid-fast bacilli (AFB), (e.g. *Mycobacterium tuberculosis*) from non-acid-fast bacilli.

Culture

Depending on the type of specimen, various culture media are used (Chapter 4). Combination of blood agar and MacConkey agar is most commonly employed for most specimens, such as pus, wound swab and other exudate specimens, sterile body fluids, urine, sputum and other respiratory specimens.

- Chocolate agar should be added for respiratory and sterile body fluid specimens.
- Stool specimen should be inoculated on to selective media, such as:
  - Mildly selective media—MacConkey agar and
  - Highly selective media—DCA, XLD and TCBS
- Blood specimen should be directly inoculated into blood culture bottles without performing direct microscopy methods.
- CLED agar can be used for urine specimen as a substitute to blood agar and MacConkey agar combination.

Morphology of Bacterial Colony

The appearance of bacterial colony on culture medium is usually characteristic which helps in preliminary identification. The following features of the colony are studied.

- Size—In millimetres, e.g. pin head size is characteristic of staphylococcal colony and pin point size is characteristic of streptococci colony
- Shape—Circular or irregular
- Surface —Glistening or dull
- Edge—Entire, crenated, lobate, undulated or filamentous
- Elevation—Flat, raised, convex, umbonate, or pulvinate
- Consistency—Mucoid, friable, firm, or butyrous
- Density—Opaque, translucent or transparent
- Hemolysis on blood agar (see below)
- Color of the colony—Colonies may be colored due to properties of the media used or due to pigment production.
  - In some differential and selective media, a few bacteria produce colored colonies due to change of pH or enzymatic activity (e.g. pink colony of *E. coli* on MacConkey agar, black colony of *C. diphtheriae* on potassium tellurite agar).
  - Pigment produced by certain bacteria may also color the colony. Pigments are of two types.
    1. **Diffusible pigments:** They diffuse throughout the media, e.g. blue green pigments produced by *Pseudomonas aeruginosa*.
    2. **Non-diffusible pigments:** They do not diffuse into surrounding media, hence only colonies are colored, not the surrounding media, e.g. golden yellow colonies of *Staphylococcus aureus*.

Hemolysis on Blood Agar

Certain bacteria produce hemolysin enzymes that lyse the red blood cells surrounding the colonies, forming a zone of hemolysis (Fig. 5.2). Hemolysis may be:

- **Partial or α hemolysis:** Partial clearing of blood around the colonies occurs with green discoloration of the surrounding medium, outline of the RBCs is intact (e.g. pneumococci)
- **Complete or β hemolysis:** Zone of complete clearing of blood around the colonies due to complete lysis of the RBCs (e.g. *Staphylococcus aureus*)
- **No hemolysis (γ hemolysis, a misnomer):** There is no color change surrounding the colony (e.g. *Enterococcus*).
- **α prime hemolysis:** Halo of incomplete lysis immediately surrounding the colonies with a second zone of complete hemolysis at the periphery.

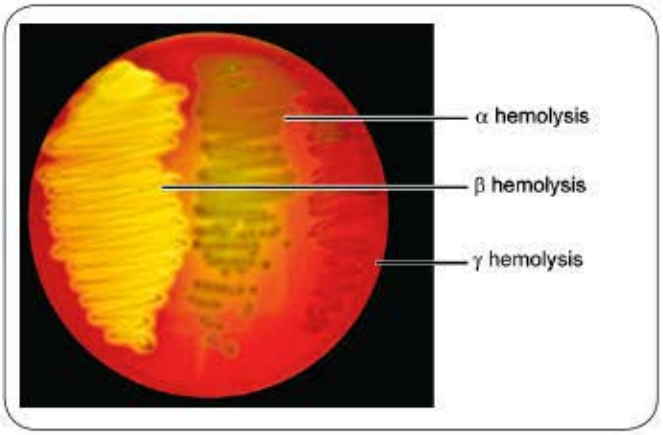


Fig. 5.2: Hemolysis on blood agar

Culture Smear and Motility Testing

The colonies grown on the culture media should be subjected to Gram staining and motility testing by hanging drop method.

Biochemical Reactions

Based on the type of organisms observed in culture smear, the appropriate biochemical tests are employed.

1. Initially, catalase and oxidase tests are done on all types of colonies grown on the media.
2. For gram-negative bacilli: Common biochemical tests done routinely are abbreviated as 'ICUT':
   - Indole test
   - Citrate utilization test
   - Urea hydrolysis test
   - Triple sugar iron test (TSI)

   If there is any doubt in correct identification of bacteria, then further biochemical tests are put, such as:
   - Sugar fermentation test
   - MR (methyl red) test
   - VP (Voges Proskauer) test
   - OF test (oxidation–fermentation test)
   - Nitrate reduction test
   - Decarboxylase test
   - PPA test (phenyl pyruvic acid test)
3. For gram-positive cocci; certain useful biochemical tests are:
   - Coagulase test (for *Staphylococcus aureus*)
   - DNase test (for *Staphylococcus aureus*)
   - CAMP (Christie Atkins Munch-Petersen) test for group B *Streptococcus*.
   - Bile esculin hydrolysis test (for *Enterococcus*)
   - Heat tolerance test (for *Enterococcus*)
   - Sugar fermentation test is useful for:
     - Pneumococcus (inulin fermentation) and
     - Species identification of coagulase negative *Staphylococcus* and *Enterococcus*)
   - PYR test (for *Streptococcus pyogenes* and *Enterococcus*)
   - Bile solubility test (for pneumococcus)
   - Antimicrobial susceptibility tests done for bacterial identification are as follows:
     - Novobiocin susceptibility test—done for *Staphylococcus saprophyticus*
     - Optochin susceptibility test (for pneumococcus)
     - Bacitracin susceptibility test-done to differentiate group A and group B *Streptococcus*)

Some of the important biochemical tests are described below. Coagulase test and other biochemical reactions for gram-positive cocci are described in the respective chapters.

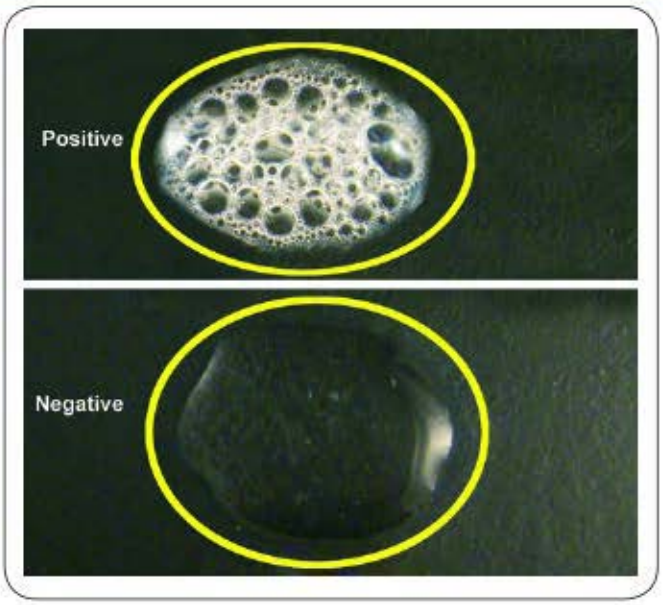

Fig. 5.3: Catalase test

Catalase Test

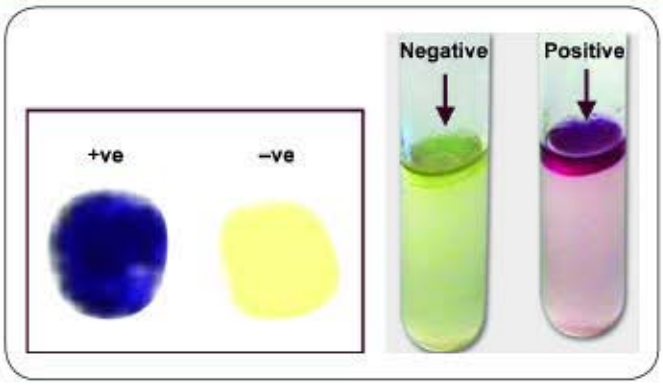
When a drop of hydrogen peroxide (3% H_2O_2) is added to a colony (or when the colony is mixed to a drop of H_2O_2 placed on a slide) of any catalase producing bacteria, effervescence or bubbles appear due to breakdown of H_2O_2 by catalase to produce oxygen (Fig. 5.3).

- Catalase test is primarily used to differentiate between *Staphylococcus* (catalase positive) from *Streptococcus* (catalase negative).
- It is also positive for members of the families Enterobacteriaceae, Vibrionaceae, etc.
- False-positive: Since blood contains catalase, colonies from blood agar may result in false-positive reaction. Use of iron wire/loop for picking up colonies may also produce false-positive test.
- Nutrient agar is the ideal medium to perform the catalase test and the colonies should be picked by glass/wooden sticks (e.g. tooth picks).

Oxidase Tests

It detects the presence of cytochrome oxidase enzyme in bacteria, which catalyses the oxidation of reduced cytochrome by atmospheric oxygen.

- When a filter paper strip or disk, soaked in oxidase reagent (1% tetramethyl para-phenylenediamine dihydrochloride), is smeared with a bacterial colony producing cytochrome oxidase enzyme, the smeared area turns deep purple within 10 seconds due to oxidation of the dye to form a purple colored compound indophenol blue.



Figs 5.4A and B: A. Oxidase test; **B.** Indole test

- Interpretation (Fig. 5.4A) and examples:
  - **Oxidase positive (deep purple):** Examples include *Pseudomonas, Vibrio, Neisseria, Bacillus*, etc.
  - **Oxidase negative (no color change):** Examples include; members of family Enterobacteriaceae, etc.

Indole Test

It detects the ability of certain bacteria to produce enzyme tryptophanase that breaks down amino acid tryptophan present in the medium into indole.

- When Kovac's reagent (para-dimethylamino-benzaldehyde) is added to an overnight incubated broth of a bacterial colony, it complexes with indole to produce a cherry red color ring near the surface of the medium.
- **Indole positive (Fig. 5.4B):** A red colored ring is formed near the surface of the broth. Examples include *Escherichia coli, Proteus vulgaris, Vibrio cholerae*, etc.
- **Indole negative (Fig. 5.4B):** Yellow colored ring is formed near the surface of the broth, e.g. *Klebsiella, Proteus mirabilis, Pseudomonas, Shigella, Salmonella*, etc.

Citrate Utilization Test

It detects the ability of a few bacteria to utilize citrate as the sole source of carbon for their growth, with production of alkaline metabolic products. Citrate test is performed on a citrate containing medium, such as Simmon's (solid) or Koser's (liquid) medium.

- **Simmon's citrate medium:** Citrate utilizing bacteria produce growth and a color change i.e. original green color changes to blue. Here bromothymol blue is used as an indicator (Fig. 5.5A).
- **Koser's (liquid) medium:** It becomes turbid, by the growth of citrate utilizing bacteria.
- Citrate test is positive for *Klebsiella pneumoniae, Citrobacter, Enterobacter*, etc.
- The test is negative for *Escherichia coli, Shigella*, etc.

Urea Hydrolysis Test

Urease producing bacteria can split urea present in the medium to produce ammonia that makes the medium alkaline.

- Test is done on Christensen's urea medium, which contain phenol red indicator that changes to pink colour in alkaline medium (Fig. 5.5B).
- **Urease test is positive for:** *Klebsiella pneumoniae, Proteus* species, *Helicobacter pylori, Brucella*, etc.
- **Urease test is negetive for:** *Escherichia coli, Shigella, Salmonella*, etc.

Triple Sugar Iron (TSI) Agar Test

TSI is a very important medium employed widely for identification of gram-negative bacteria.

Composition

It is a composite solid agar medium in tube having a butt and a slant. Its constituents include:

- Three sugars-glucose, sucrose and lactose in the ratio of 1:10:10 parts.
- Phenol red as an indicator of acid production.
- Ferric salts as an indicator of hydrogen sulfide (H_2S) production.

Procedure

Medium is inoculated with a pure bacterial culture by a straight wire pierced deep in the butt (stab culture) and then doing a stroke culture on the slant area. The tube is incubated at 37°C for 18–24 hours. Under incubation or over incubation may lead to false interpretation of result.

Interpretation

TSI detects three properties of bacteria, such as fermentation of sugars to produce acid and/or gas and production of H_2S.

- **Ability to ferment sugars to produce acid:** Uninoculated TSI medium is red in color (Fig. 5.6A) and on acid production the color changes to yellow. Based on fermentation of sugar present in TSI, the organisms are categorized into three groups (Table 5.2, Fig. 5.6).
  1. **Nonfermenters:** They do not ferment any sugars, hence an alkaline slant and alkaline butt (no change) reaction is observed, (K/K reaction or alkaline (red) slant/ alkaline (red) butt (Fig. 5.6F).
  2. **Glucose only fermenters:** They ferment only glucose and produce little acid. Initially at 8 hours, the whole medium turns acidic (yellow). Later on, the organism begins oxidative degradation of the peptones present in the slant, resulting in alkaline by-products in slant, which change the indicator back to red color. At 18–24 hours, the medium

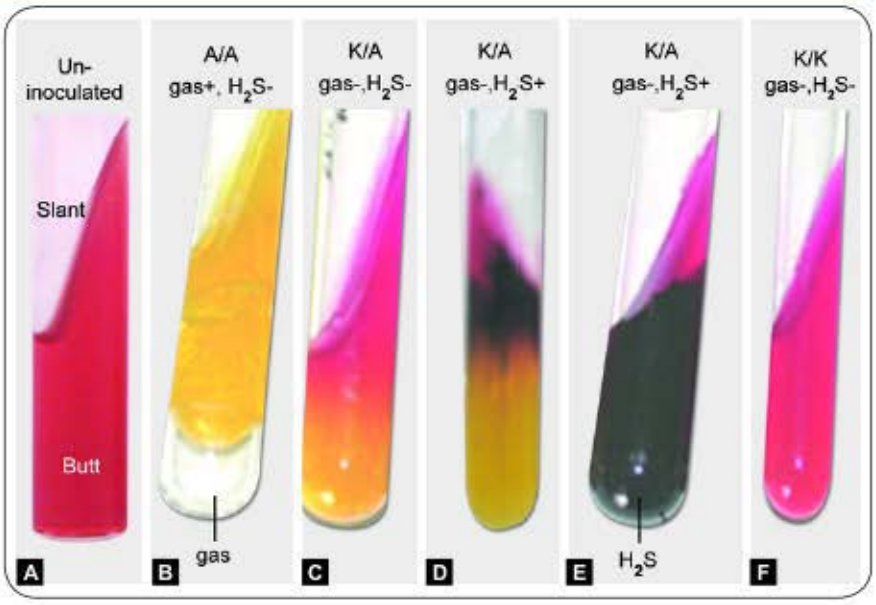


Figs 5.6A to F: Triple sugar iron test

TABLE 5.2: Various reactions in TSI with examples

Reactions in TSI	Examples
Acidic slant/acidic butt	**≥2 sugars fermented** (1) glucose, (2) lactose or/and sucrose
A/A, gas produced, no H_2S (Fig. 5.6B)	*Escherichia coli* *Klebsiella pneumoniae*
Alkaline slant/acidic butt	**Only glucose fermenter group**
K/A, no gas, no H_2S (Fig. 5.6C)	*Shigella*
K/A, no gas, H_2S produced (small amount), Fig. 5.6D	*Salmonella* Typhi
K/A, no gas, H_2S produced (abundant), Fig. 5.6E	*Proteus vulgaris*
K/A, gas produced, H_2S produced (abundant)	*Salmonella* Paratyphi B
K/A, gas produced, no H_2S	*Salmonella* Paratyphi A
Alkaline slant/alkaline butt	**Non fermenters group**
K/K, no gas, no H_2S (Fig. 5.6F)	*Pseudomonas* *Acinetobacter*

appears alkaline (red) slant/acidic (yellow) butt or K/A reaction (Fig. 5.6C).

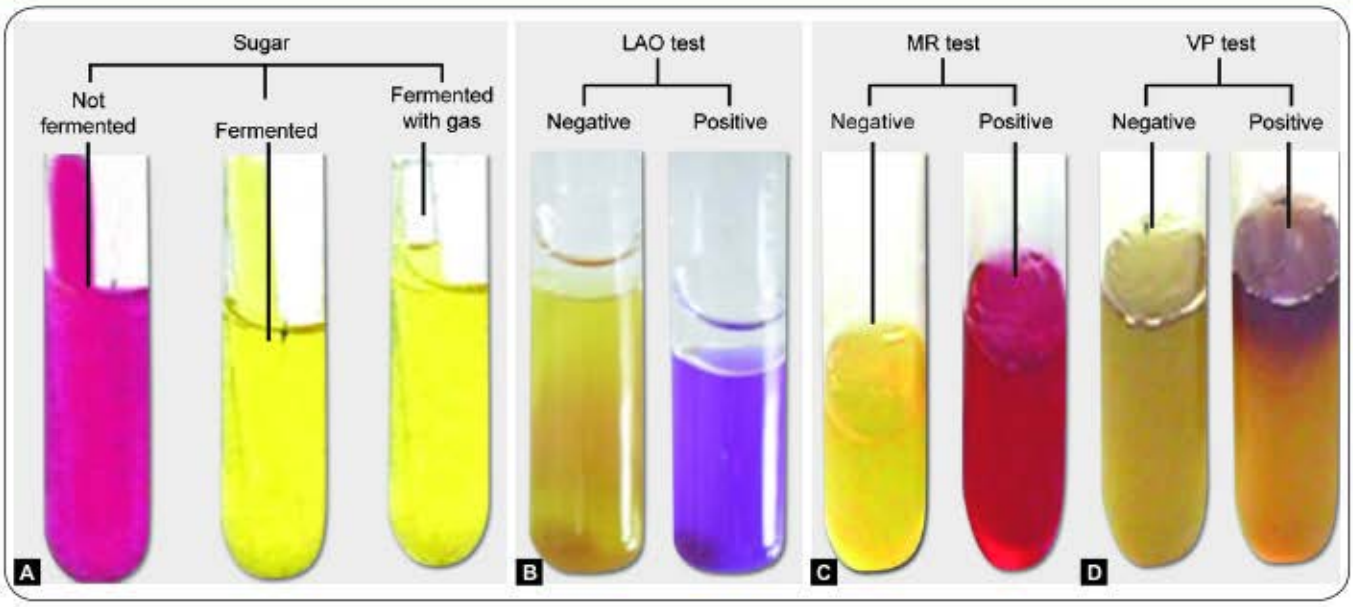
3. **Lactose and/or sucrose fermenters:** They ferment glucose and also ferment lactose and/or sucrose to produce large amount of acid so that the medium turns acidic at 8 hours. At 18–24 hours, the medium maintains acidic pH both in slant and butt and gives an acidic (yellow) slant/ acidic (yellow) butt or A/A reaction (Fig. 5.6B).

- **Ability to produce gas:** Some bacteria produce gas by sugar fermentation; which is denoted by breaks/ cracks in the medium or the medium is lifted up (Fig. 5.6B).
- **Ability to produce H_2S:** Certain bacteria produce hydrogen sulphide (H_2S), which is a colorless gas. H_2S combines with ferric ions (from ferric salts present in the medium) to form ferrous sulfide, that produces blackening of the medium (Figs 5.6D and E).

Sugar Fermentation Test

It detects the ability of an organism to ferment a specific carbohydrate (sugar) incorporated in a medium producing acid with/without gas. Glucose, lactose, sucrose and mannitol are widely used for sugar fermentation.

- Ordinary sugar media contain 0.5% sugar and an indicator.
- Enriched sugar media called serum (Hiss's) sugar media containing 1% sugar are used for detecting fermentation by fastidious organisms, such as pneumococci, *Neisseria*, *Corynebacterium*, etc.
- Acid production is detected by using indicators, such as:
  - Andrade's indicator (a solution of acid fuchsin and sodium hydroxide): It is colorless, turns pink in acidic medium.
  - Phenol red indicator: It is red in color, turns yellow in acidic medium (Fig. 5.7A).
- Gas production is detected by using an inverted Durham's tube (Fig. 5.7A).



Figs 5.7A to D: **A.** Sugar fermentation test; **B.** Decarboxylase test; **C.** Methyl red test; **D.** Voges Proskauer test

Decarboxylase Test

It detects the presence of substrate specific decarboxylase enzyme in the bacteria that break down amino acids, such as lysine, arginine and ornithine to produce alkaline by-products which change the color of the indicator to purple (Fig. 5.7B). Cresol red and bromocresol purple are used as indicators.

Lysine —(Lysine decarboxylase)→ Cadaverine
Ornithine —(Ornithine decarboxylase)→ Putrescine
Arginine —(Arginine dihydrolase)→ Citrulline

Methyl Red (MR) Test

In glucose phosphate broth, certain bacteria ferment glucose to produce stronger acids (lactic, acetic or formic) that maintain the pH below 4.4, which turns methyl red indicator from yellow to red color (Fig. 5.7C).

- MR Positive (red color)—*Escherichia coli*
- MR negative (no change in color)— *Klebsiella pneumoniae*.

Voges Proskauer (VP) Test

This test is also done in glucose phosphate broth. Certain bacteria produce acetoin (acetyl methyl carbinol) as chief end product of glucose fermentation. In the presence of alkali (40% potassium hydroxide VP reagent-II) and atmospheric oxygen, acetoin is oxidized to diacetyl which reacts with α-naphthol (VP reagent-I) to give red color (Fig. 5.7D).

- **VP positive:** *Klebsiella pneumoniae, Enterobacter,* El Tor vibrios, *Staphylococcus*, etc.
- **VP negative:** *Escherichia coli, Shigella, Salmonella*, etc.

Oxidation–Fermentation Test (OF test)

Hugh and leifson OF test differentiates between fermenters and non-fermenters (that utilize sugars oxidatively). OF medium differs from ordinary sugar fermentation medium by containing:

- Agar (0.3%)- making the medium semisolid that permits the diffusion of acids from the surface to throughout the medium changing the color of the bromothymol blue indicator to yellow (Fig. 5.8A).
- Increased sugar concentration from 0.5% to 1%.
- Decreased peptone concentration from 1% to 0.2%.

The test organism is inoculated in OF medium in duplicate and one of the tubes is covered with 1 cm layer of liquid paraffin to create anaerobic environment. Acid production changes the color of the medium from green to yellow. If the sugar is fermentatively utilized, acid is produced in both the tubes, whereas the non-fermenters utilize the sugars oxidatively only in the tube without liquid paraffin overlay. Asaccharolytic bacteria cannot utilize the sugars in both the tubes (Fig. 5.8A, Table 5.3).

Nitrate Reduction Test

This test detects the presence of an enzyme nitrate reductase in the organism, which reduces nitrate present in the medium (nitrate broth) to nitrite or free nitrogen gas.

- Nitrite production is detected by adding the nitrate reagent (sulfanilic acid and alpha-naphthylamine)- Changes the medium to red from yellow (Fig. 5.8B).
- Free nitrogen gas is detected by using a Durham's tube.
- Nitrate test positive: e.g. all the members of family Enterobacteriaceae.

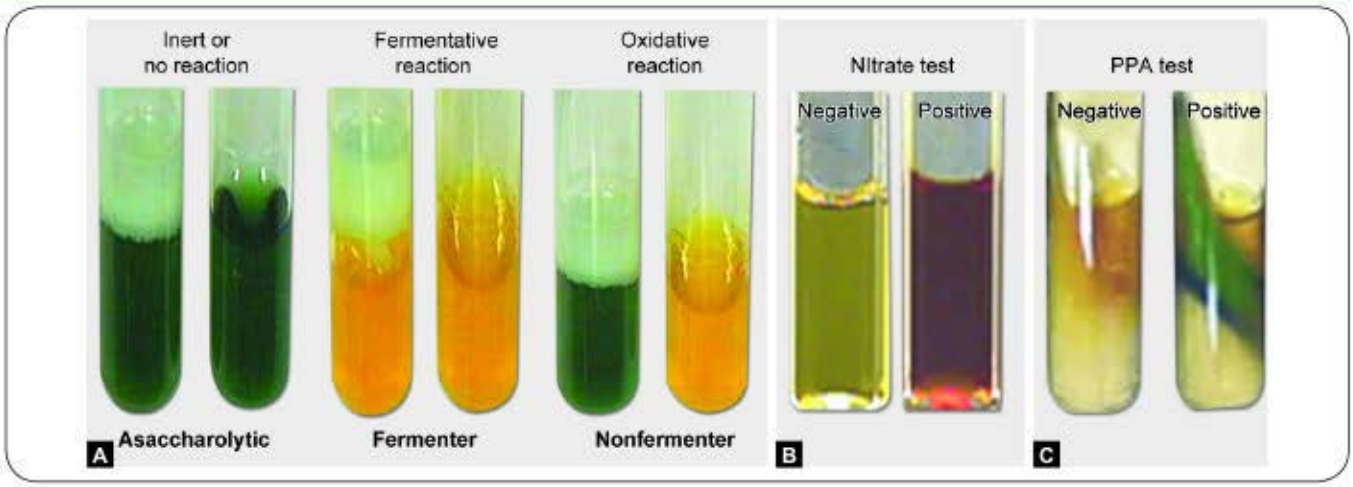


Fig. 5.8A to C: **A.** Oxidation–fermentation (OF) test; **B.** Nitrate reduction test; **C.** PPA test

TABLE 5.3: Oxidation–fermentation test—results and interpretations

Open tube	Covered tube	Metabolism
Acid (yellow)	Acid (yellow)	Fermentative bacteria
Acid (yellow)	Alkaline (green)	Oxidative bacteria (i.e. non-fermenters)
Alkaline (green)	Alkaline (green)	Asaccharolytic bacteria

Phenyl Pyruvic Acid Test (PPA test)

This is a specific test done for members of tribe Proteeae; which includes *Proteus, Morganella* and *Providencia*. They possess a specific enzyme that deaminates phenylalanine present in the medium to phenyl pyruvic acid (PPA). PPA reacts with few drops of 10% ferric chloride solution to produce green color (Fig. 5.8C).

AUTOMATED CULTURE TECHNIQUES

Automated or instrument-based techniques are available for various purposes, such as culture, identification, antimicrobial susceptibility testing, etc.

Automated Blood Culture Techniques

Conventional blood culture methods often yield poor results because of low bacterial load and increased chance of contamination. Therefore, various automated blood culture techniques have been in use since last decade.

Advantages

The major advantages of automated blood culture techniques are:

- **Continuous automated monitoring:** Following inoculation, the culture bottles are kept within the automated culture system, where they are incubated and periodically monitored for the microbial growth once in every 15-20 minutes by the instrument. Once positive for microbial growth, the instrument gives a signal (producing beep or color change on the screen).
- **More sensitive:** It gives a higher yield of positive cultures from clinical specimens.
- **Rapid:** Takes much less time than conventional methods.
- **Less labor intensive:** Saves man power.

Disadvantages

Automated culture methods do have several disadvantages like (1) high cost of the instrument and culture bottles, (2) inability to observe the colony morphology as liquid medium is used, (3) no separate detection in mixed cultures, (4) ↑overgrowth by contaminants, and (5) for techniques based on radiometric detection—there is need for disposal of radioactive materials.

There are several companies that manufacture automated blood culture systems which detect the bacterial growth based on different principles (Table 5.4).

Automated Systems for Bacterial Identification

Automated culture systems described above, give information only about a positive microbial growth; however, it does not help in identification of the organism. Traditionally, the bacterial identification is carried out by performing a series of biochemical tests. In modern era, various automated systems are available which help in bacterial identification, such as:

- Phoenix bacterial identification system (BD biosciences) (Fig. 5.9)
- MALDI-TOF (Matrix-assisted laser desorption/ionization time-of-flight), e.g. VITEK MS (bioMerieux)
- VITEK 2 bacterial identification and antimicrobial sensitivity system (bioMerieux)

TABLE 5.4: Common automated blood culture systems

Systems and manufacturer	Methods used for detection of growth of microorganisms
BACTEC (BD biosciences)	▪ In this automated system, earlier versions were based on the use of radioisotopes to detect growth. They are not in use currently. ▪ Current versions are based on fluorescent detection: ▪ It uses an oxygen sensitive fluorescent compound, dissolved in the broth. ▪ In uninoculated broth, the large amount of dissolved oxygen quenches the fluorescence dye. ▪ Later, actively microorganisms consume the oxygen removing the quenching effect and allowing the fluorescence to be detected.
BacT/Alert (bioMerieux)	CO_2 liberated from bacteria, causes a pH change, detected by colorimetry
ESP culture system	CO_2 liberated from bacteria, causes a pressure change, detected by manometry (Trek diagnostic system)

- MicroScanWalkAway system (Beckman Coulter).

It employs a card/tray/panel containing wells or test areas for a series of biochemical reactions. Following inoculation of the culture suspension of the test organism, the card/tray/ panel is placed inside the instrument within which the biochemical tests are performed automatically. The instruments display the result of the biochemical tests along with identification of the test organism.

Automated techniques for antimicrobial susceptibility testing have been described in Chapter 7. Automated techniques for mycobacterial culture and susceptibility testing have been described in Chapter 27.

MOLECULAR METHODS

Nucleic acid amplification techniques (NAATs) have been increasingly used in diagnostic microbiology. Various NAATs used are:

- Polymerase chain reaction (PCR)
- Real-time polymerase chain reaction
- Ligase chain reaction (LCR)
- Transcription-mediated amplification (TMA)
- Nucleic acid sequence-based amplification (NASBA)
- Strand displacement amplification (SDA)

Polymerase Chain Reaction (PCR)

PCR is a technology in molecular biology used to amplify a single or few copies of a piece of DNA to generate millions of copies of DNA. It was developed by Kary B Mullis (1983) for which he and Michael Smith were awarded the Nobel prize in Chemistry in 1993.

Fig. 5.9: Phoenix bacterial culture and identification system with culture bottles (BD biosciences)

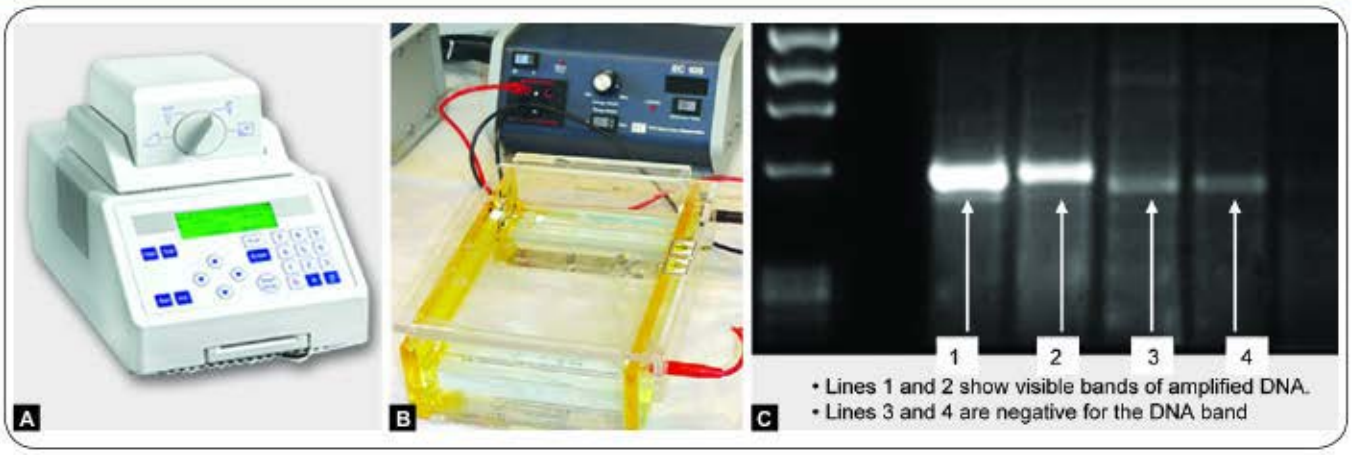
Principle

PCR involves three basic steps.

1. **DNA extraction from the organism:** This involves lysis of the organisms and release of the DNA which may be done by various methods, such as boiling, adding enzymes, such as lysozyme, proteinase K, etc. phenol chloroform isoamyl alcohol method. DNA extraction kits are also available commercially.
2. **Amplification of extracted DNA:** This is carried out in a special PCR machine called thermocycler (Fig. 5.10A). The extracted DNA is subjected to repeated cycles (30–35 numbers) of amplification which takes about 3–4 hours. Each amplification cycle has three steps (Fig. 5.11).
   - **Denaturation at 95°C:** This involves separation of the dsDNA into two separate single strands.
   - **Primer annealing (55°C):** Primer is a short oligonucleotide complementary to a small sequence of the target DNA. It anneals to the complementary site on the target ssDNA.
   - **Extension of the primer (72°C):** This step is catalysed by Taq Polymerase enzyme which keeps on adding the free nucleotides to the growing end of the primer.
     Taq Polymerase is a special type of DNA polymerase (isolated from the plant bacterium *Thermus aquaticus*), capable of withstanding the high temperature of PCR reaction.
3. **Gel electrophoresis of amplified product:** The amplified DNA is electrophoretically migrated according to their molecular size by performing agarose gel electrophoresis (Fig. 5.10B). The amplified DNA forms clear bands which can be visualized under ultraviolet (UV) light (Fig. 5.10C).

Applications of PCR

Polymerase chain reaction is now a common and often indispensable technique used in medical diagnostics and research laboratories for a variety of applications. It has the following advantages compared to the conventional culture methods:



Figs 5.10A to C: **A.** Thermocycler machine (Eppendorf); **B.** Gel electrophoresis of amplified product; **C.** Visualisation of amplified DNA under UV light

- **More sensitive:** It can amplify very few copies of a specific DNA, so it is more sensitive.
- **More specific:** Use of primers targeting specific DNA sequence of the organism makes the PCR assays highly specific.
- PCR can be done to amplify the DNA of the organism: (1) either directly from the sample, or (2) to confirm the organism grown in culture.
- PCR can also detect the organisms that are highly fastidious or noncultivable by conventional culture methods.
- PCR can be used to detect the genes in the organism responsible for drug resistance (e.g. *MecA* gene detection in *Staphylococcus aureus*)
- Detects genetic diseases, such as sickle cell anemia, phenylketonuria, and muscular dystrophy.

Disadvantages of PCR

Conventional PCR detects only the DNA, but not the RNA (latter can be detected by reverse transcriptase PCR).

- **Qualitative, not quantitative:** Conventional PCR can only detect the presence or absence of DNA. It cannot quantitate the amount of DNA of the organism present in the sample. This is possible by real time PCR.
- **Viability:** PCR cannot differentiate between viable or nonviable organisms. It only detects the presence of DNA in the sample which may be extracted from viable or nonviable organism.
- **False-positive amplification:** It may occur due to contamination with environmental DNA. Hence, strict asepsis should be maintained in the PCR lab.

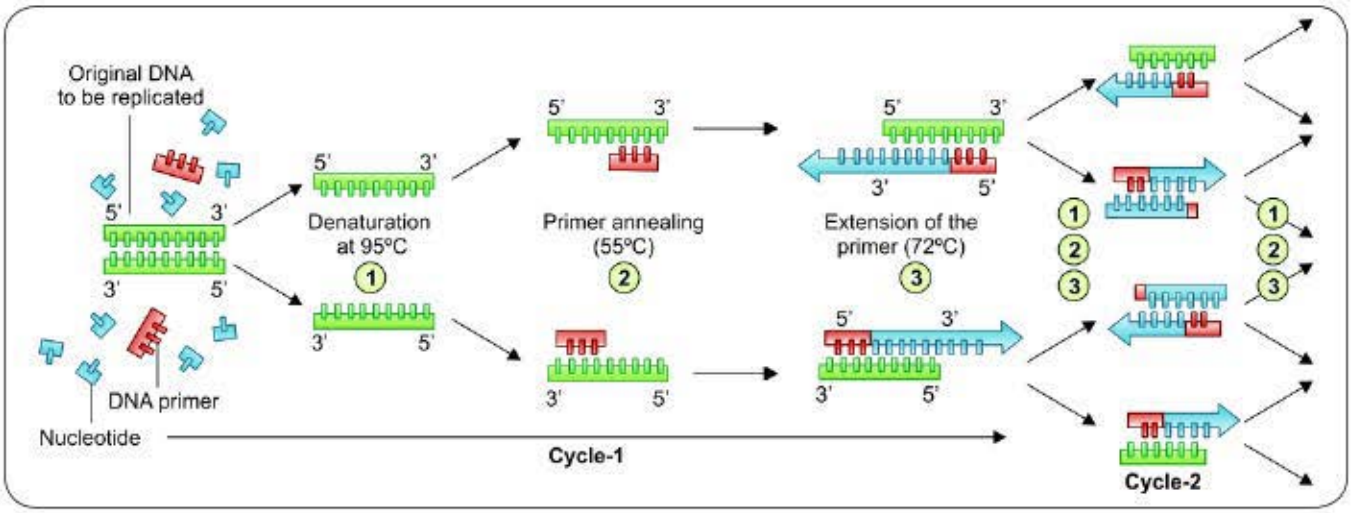


Fig. 5.11: Polymerase chain reaction cycle—3 basic steps of amplification

- **False-negative:** The PCR inhibitors present in some specimens, such as blood, feces, etc may inhibit the amplification of target DNA.

Modification of PCR

1. **Reverse transcriptase PCR (RT-PCR):** Conventional PCR amplifies only the DNA. For amplifying RNA, RT-PCR is done.
   - After RNA extraction, the first step is addition of reverse transcriptase enzyme that coverts RNA into DNA. Then, the amplification of DNA and gel documentation steps are similar to that described for conventional PCR.
   - It is extremely useful for detection of RNA viruses or 16S rRNA genes of the organisms.
2. **Nested PCR:** It is modification of PCR, where two rounds of PCR amplification are carried out by using two primers that are targeted against two different DNA sequences of same organism.
   - The amplified products of the first round PCR is subjected to another round of amplification using a second primer which targets the same organism but a different DNA sequence.
   - More sensitive: Double round of amplification yields high quantity of DNA.
   - More specific: Use of two primers targeting two regions of DNA of the same organisms makes the test more specific.
   - Application: Nested PCR is used for detection of *Mycobacterium tuberculosis* (targeting IS6110 gene) in samples.
   - Disadvantage: There is more chance of contamination of the PCR tubes, which may lead to false-positive results.
3. **Multiplex PCR:** It uses more than one primer which can detect many DNA sequences of several organisms in one reaction.
   - Syndromic approach: Multiplex PCR is useful for the diagnosis of the infectious diseases that are caused by more than one organism.
   - For example, for the etiological diagnosis of pyogenic meningitis, different primers targeting the common agents of pyogenic meningitis, such as pneumococcus, meningococcus and *H. influenzae* can be added simultaneously in the same reaction tube.
   - Contamination issues: There are chances of the reaction tubes being contaminated with environmental DNA.

Real-time PCR (rt-PCR)

It is based on PCR technology, which is used to amplify and simultaneously detect or quantify a targeted DNA molecule on real-time basis. Reverse transcriptase real-time PCR formats can detect and quantify RNA molecules of the test organism in the sample on real-time basis.

It uses a different thermocycler than the conventional PCR. It is very expensive, 10 times more than the cost of conventional PCR.

Advantages: Real-time PCR has many advantages over a conventional PCR, such as:

- Quantitative: rt-PCR can quantitate the DNA present in the specimen; hence can be used for monitoring the disease progression in response to treatment, e.g. viral load monitoring in HIV or hepatitis B viral infection.
- Takes less time: In rt-PCR, the amplification can be visualized simultaneously during the process of amplification unlike the conventional PCR where there is an extra-step of electrophoresis to detect the amplicons.
- Contamination rate is extremely less.
- Sensitivity and specificity of rt-PCR assays are extremely much more than the conventional PCR.

Detection of amplification products of real-time PCR: The detection of amplified nucleic acid in a real-time PCR reaction is carried out by using a variety of fluorogenic molecules which may be either nonspecific or specific.

- Nonspecific methods: They use SYBR green dye that stains any nucleic acid nonspecifically.
- Specific methods: They use fluorescent labeled oligonucleotide probe which binds (i.e. hybridizes) only to a particular region of amplified nucleic acid. Three types of hybridization probes are commonly used:
  - TaqMan or hydrolysis probe
  - Molecular beacon
  - Fluorescence resonance energy transfer (FRET) probe

Post-amplification melting curve analysis has been used for quantitation of the nucleic acid load.

MICROBIAL TYPING

Microbial typing refers to characterization of an organism beyond its species level.

Applications: Microbial typing is an important tool for hospital microbiologists and epidemiologists. It is used to determine the relatedness between different microbial strains of the same species and thereby it helps to:

- Investigate outbreaks: All isolates tracked in an outbreak should belong to similar type.
- Determine the source and routes of infections.
- Trace cross-infection, i.e. transmission of healthcare-associated pathogens.
- Differentiate virulent strains from avirulent strains of same species.
- Differentiate between recurrence and infection with new strain.
- Evaluate the effectiveness of control measures.

Classification: Typing methods are broadly classified as phenotypic and genotypic methods (Table 5.5).

Characteristic of Typing Methods

A good typing method should have the following properties:

- **Typeability:** Ability of the method to type and generate a result for each isolate tested.

TABLE 5.5: Typing methods

Phenotypic methods	Genotypic methods
Bacteriophage typing	**Non-amplification-based methods**
Bacteriocin typing	Plasmid profile analysis
Biotyping	Chromosomal DNA analysis
Antibiogram typing	RFLP(Restricted fragment length polymorphism)
Auxotyping	Ribotyping (RFLP analysis of ribosomal DNA)
Morphotyping	Pulse field gel electrophoresis (PFGE)
Serotyping	**Amplification-based methods**
	PCR-RFLP
	Amplified fragment length polymorphism (AFLP)
	Sequencing-based methods
	Microarrays

- **Reproducibility:** Ability to produce similar results when tested repeatedly in different laboratories.
- **Discriminative power:** Ability to generate distinct units of information making fine distinctions between the types at the subspecies level,
- **Practicality:** Ease of use and interpretation, cost and affordability.

In general, genotypic methods are more reliable and have better reproducibility and discriminative power than phenotypic methods, however they are expensive.

Phenotypic Methods

Bacteriophage Typing

Strains of an organism can be further differentiated into subspecies level based on their susceptibility to bacteriophages. The procedure is described in Chapter 21. Phage typing is useful for the typing of:

- *Staphylococcus aureus*
- *Salmonella* Typhi
- *Vibrio* species
- *Brucella* species
- *Corynebacterium diphtheriae*

Bacteriocin Typing

Bacteriocin is an antibiotic like proteinaceous substance produced by one bacterium that inhibits other strains of the same or other closely related bacteria. Bacteriocin typing is based on the ability of a strain to produce particular bacteriocin which inhibits the growth of a set of selected indicator strains. It is done for:

- *Shigella sonnei* (colicin typing)
- *Klebsiella* (klebocin typing)
- *Escherichia coli* (colicin typing)
- *Proteus* (proticin typing)
- *Pseudomonas* (pyocin typing)

Biotyping

It refers to intra species classification based on different biochemical properties of the organism. It is used for:

- *Corynebacterium diphtheriae:* It is classified into gravis, intermedius and mitis.
- *Vibrio cholerae* O1 is classified into two biotypes -classical and El Tor
- *Yersinia pestis.*

Antibiogram Typing

It classifies the organism into different groups based on their resistance pattern to different antimicrobials. Since antimicrobial susceptibility testing is routinely done in any hospital, this typing system provides the first clue to a microbiologist about outbreaks occurring in a hospital.

Auxotyping

This is a typing method based on nutritional requirement of the organism. This is done for *Neisseria gonorrhoeae.*

Morphotyping

This is based on different morphological appearances of the colonies in the culture media.This is done for *Pseudomonas.*

Serotyping

It refers to a typing method based on the antigenic property of an organism. This is the most widely used and the most reliable phenotypic typing method. Serotyping is done for many organisms; important ones are given below.

- *Streptococcus* (Lancefield grouping, based on carbohydrate antigen).
- Based on capsular antigen—e.g. pneumococcus, meningococcus and *Haemophilus influenzae.*
- Based on somatic antigen—*Escherichia coli, Shigella, Salmonella* and *Vibrio cholerae.*

Genotypic Methods

Plasmid Profile Analysis

It is a method of determining a number and size of plasmids present in bacterial isolates. Plasmids produced by various strains in an outbreak are compared. First the plasmids are extracted from the bacterial cell and are then separated on agarose gel based on molecular weight followed by their detection by staining with ethidium bromide.

Restricted Fragment Length Polymorphism (RFLP)

1. **Digestion of DNA:** This is done by using 2 or more restriction enzymes which cleave the DNA from a bacterial strain at different sites so that multiple DNA fragments are generated.
2. **Southern blot to detect DNA fragments:** The DNA fragments are separated by electrophoresis and transferred to a nitrocellulose membrane and

then are detected by using specific DNA probes (Chapter 6).

The pattern of fragments generated by different strains tracked in an outbreak can be compared to know the relatedness between the strains.

Ribotyping

Ribotyping is a type of RFLP analysis which is done on chromosomal DNA coding for ribosomal RNA.

Pulse Field Gel Electrophoresis (PFGE)

PFGE is considered as a **gold standard** method in epidemiological investigation of pathogenic organisms. It has the following unique properties:

- **Lysis:** First, the bacterial suspension is loaded into an agarose suspension. This is done to protect the chromosomal DNA from mechanical damage by immobilizing it into agarose blocks. Then the bacterial cell is lysed to release the DNA. The agarose-DNA suspension is also known as plug mold.
- **Digestion of DNA:** The bacterial DNA is treated with rare cutting restriction enzymes so that it yields generation of less number of larger size DNA fragments (in contrast to frequent cutting restriction enzymes used in RFLP which produces large number of smaller fragments).
- **Electrophoresis:** The larger pieces of DNA are subjected to pulse field gel electrophoresis by applying electric current and altering its direction at a regular interval (in contrast to the conventional agarose gel electrophoresis done to separate the smaller fragments where the current is applied in a single direction).
- **Analysis:** The fragments generated by PFGE of various strains obtained during an outbreak are compared manually or by computer software BioNumerics.

The drawbacks of PFGE are (1) it is labor intensive, (2) requires many days to perform the procedure, (3) requires skilled personnel to interpret the results and (4) requires computer-assisted analysis of banding patterns.

Amplified Fragment Length Polymorphism (AFLP)

AFLP uses the principle of performing RFLP of the bacterial DNA followed by PCR.

- The genomic DNA is digested by restriction enzymes, followed by use of adaptors to ligate to the sticky ends of the restriction fragments.
- PCR amplification of the restriction fragments is carried out by using primers complementary to both adaptor and restriction site sequences.
- The amplified fragments are separated and visualized on denaturing polyacrylamide gels.

Sequencing-based Methods

The nucleotide sequence of a microbial gene can be obtained by specially designed equipment called *sequencer*. The variability within the sequences of particular genes can be used to determine the relatedness of bacteria. Sequence analysis can be done:

- At a single nucleotide (single nucleotide polymorphism or SNP analysis).
- Multiple genes (multilocus sequence typing or MLST).
- Whole genome sequencing.

Microarrays

Microarray technology offers a wide range of analysis of simultaneous detection of multiple gene products, such as antibiotic resistance determinants and virulence factors whose identification can be useful for epidemiological investigations.

- The principle of the microarray is based on generating labelled cDNA or cRNA molecules that are subsequently hybridized to an arrayed series of thousands of microscopic spots with specific complementary oligonucleotides (probes).
- DNA microarrays have been used to measure changes in expression levels and to detect SNPs. It is also used for genotyping.

EXPECTED QUESTIONS

I. Write short notes on:

1. Catalase test
2. Oxidase test
3. Triple sugar iron agar test
4. Automations in Microbiology
5. Polymerase chain reaction

II. Multiple Choice Questions (MCQs):

1. Triple sugar iron agar consists of all of the following sugars except:
a. Glucose b. Lactose c. Maltose d. Sucrose

2. All of the following are phenotypic typing methods of bacteria except:
a. Ribotyping
b. Bacteriocin typing
c. Antibiogram typing
d. Bacteriophage typing

3. All of the following are oxidase negative bacteria except:
a. *Escherichia coli* b. *Klebsiella*
c. *Proteus* d. *Pseudomonas*

Answers

1. c **2.** a **3.** d

- Transposition
- Gene transfer by artificial methods

PRINCIPLES OF BACTERIAL GENETICS

Bacterial genetics deals with the study of heredity and gene variations seen in bacteria. All hereditary characteristics of the bacteria are encoded in their DNA (deoxyribonucleic acid). Bacterial DNA is present in chromosome as well in extrachromosomal genetic material as plasmid.

BACTERIAL DNA

Bacteria possess a single haploid chromosome, comprising of super coiled circular double stranded DNA of 1 mm length. The bacterial DNA lacks basic proteins. However, some bacteria have a linear DNA chromosome and some have two chromosomes (e.g. *Vibrio cholerae*). Bacteria do not have a true nucleus; but the genetic material is located in an irregularly shaped region called the nucleoid. There is no nuclear membrane or nucleolus.

Structure of DNA (Watson and Crick Model)

The bacterial DNA molecule is composed of two strands of complementary nucleotides that are coiled together in the form of a double helix (Fig. 6.1) as described first by Watson and Crick.

- **Each strand is composed of three elements:** It has a backbone of deoxyribose sugar and phosphate groups. The nitrogenous bases are attached to the sugar group. The terms nucleotide and nucleoside are often used to describe the components of the DNA strand—
  - Nucleoside = Sugar + nitrogenous base
  - Nucleotide = Sugar + nitrogenous base + phosphate
- There are four nitrogenous bases:
  - Two purines—adenine (A) and guanine (G)
  - Two pyrimidines—thymine (T) and cytosine (C)
- **Pairing:** The two DNA strands are held together by hydrogen bonds occurring between the nitrogenous bases on the opposite strands. The pairing follows a specific rule—
  - Adenine of one strand binds with thymine (A–T) of other strand by double hydrogen bonds.
  - Guanine of one strand binds with cytosine (G–C) of other strand by triple hydrogen bonds.
- Hence, in a molecule of DNA, the number of adenine molecules is equal to that of thymine, and the number of guanines is equal to cytosines.
- The ratio of A + T to G + C is constant for each species but varies widely from one bacterial species to another.

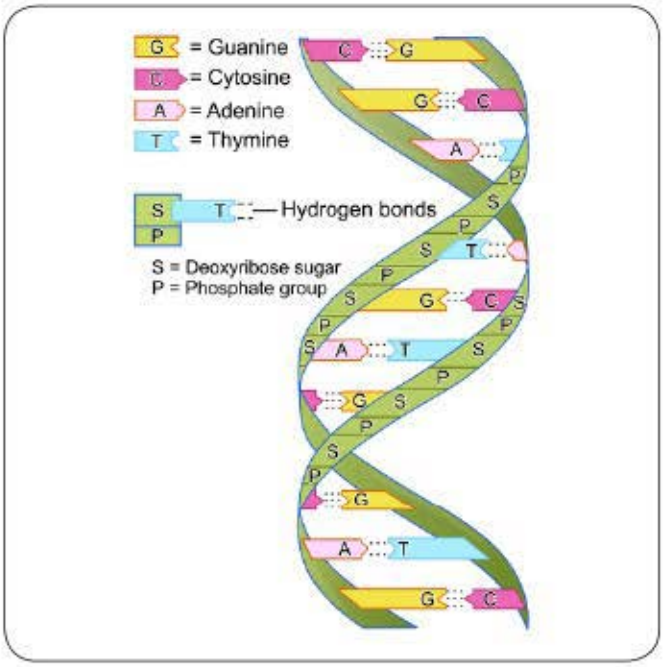

Fig. 6.1: Structure of DNA

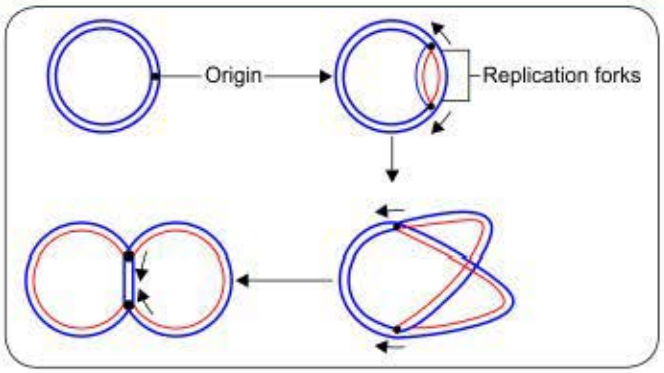

Fig. 6.2: Bidirectional replication

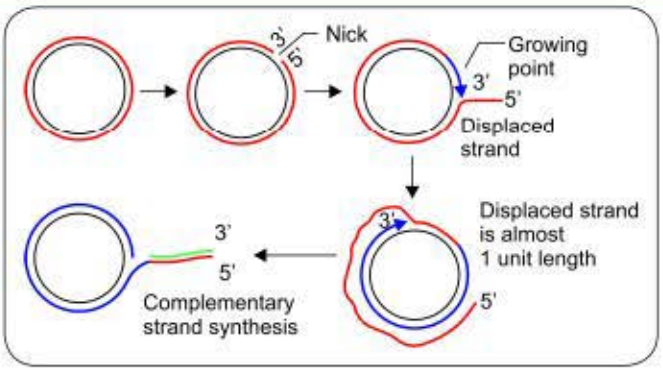

Fig. 6.3: Rolling-circle mechanism

DNA Replication

In eukaryotes, during DNA replication, the two strands of the double helix unwind from one another and separate. Each strand acts as template for a new DNA strand which is synthesized through complementary base pairing—A with T, and G with C. In prokaryotic cells, DNA replication takes place in a similar way with some differences.

Bidirectional Replication

For example in *E. coli*, the replication begins at a single point, the origin. DNA helix is unwound at a region called replication fork. It is the site at which the DNA synthesis occurs and individual strands are replicated. Two replication forks move outwards from the origin until they have copied the whole replicon and a structure shaped like the Greek letter theta (θ) is formed (Fig. 6.2). Finally, since the forks meet on the other side and two chromosomes are separated.

Rolling-circle Mechanism

This is a different pattern of DNA replication which occurs during bacterial conjugation and during the reproduction of viruses and bacteriophages.

- The outer strand is nicked and the free 3′ end is extended by replication enzymes in a manner that the growing point rolls around the circular inner strand (Fig. 6.3).
- At the same time, the 5′ end of the outer strand is displaced and forms a single-stranded tail which later may be converted to the dsDNA by complementary strand synthesis.

The DNA replication in bacteria is catalysed by several replication enzymes such as—

- **Helicase:** It is responsible for DNA unwinding
- **Topoisomerase** (e.g. DNA gyrase in *E. coli*): It relieves the tension generated by rapid unwinding by removing the super twists.
- **DNA polymerase:** It forms complementary strand synthesis by adding nucleotides to the growing end of the strand. It catalyzes the synthesis of DNA in the 5′ to 3′ direction while reading the DNA template in the 3′ to 5′ direction. DNA polymerase III plays the major role in replication, although it is probably assisted by polymerase I. It is thought that polymerases I and II participate in the repair of damaged DNA.
- **DNA ligase:** It helps in joining of the fragments.

BACTERIAL RNA

RNA (ribonucleic acid) is structurally similar to DNA, except for two differences.

- In sugar—ribose is present instead of deoxyribose and
- In nitrogenous base—uracil replaces thymine.

There are three different types of RNA in a cell, messenger RNA (mRNA), ribosomal RNA (rRNA) and transfer RNA (tRNA). The main function of RNA is protein synthesis.

POLYPEPTIDE SYNTHESIS

Gene is a segment of DNA that stores information for a particular polypeptide synthesis. The genetic information that is stored in DNA is transcribed into RNA and then translated to form the particular polypeptide.

Genetic Code

Codon: It is a sequence of three nucleotide bases present on mRNA that stores the information of an amino acid synthesis. It was discovered by Nirenberg and Khorana (1968).

- **Sense codons:** There are 64 codons, out of which 61 are sense codons, each directs the production of a single amino acid. As there are only 20 amino acids, so more than one codon exist for the same amino acid.
- **Non-sense codons:** The remaining three codons (UGA, UAG, and UAA) do not code for any amino acids and are involved in the termination of translation; hence called as stop codons.
- **Start codon:** It is the first codon of an mRNA from which the translation begins. The most common start codon

is AUG which codes for methionine in eukaryotes and modified methionine [N-Formyl methionine (fMet)] in prokaryotes.

Anticodon: It is a set of three nucleotide bases present on tRNA that is complementary to the nucleotide bases of codon on mRNA.

Transcription

Transcription is a process, in which a particular segment of DNA is copied into RNA by the enzyme RNA polymerase. Since DNA acts as a template for synthesis of mRNA, therefore, the bases in mRNA are complementary to that of DNA.

Translation

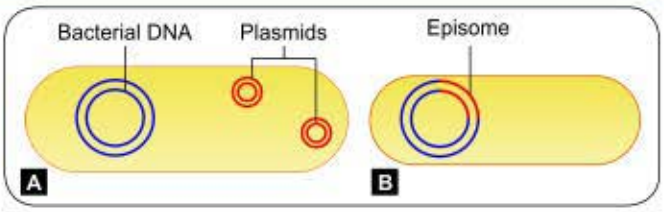
In translation, the mRNA transcribed from DNA is decoded by a ribosome to produce a specific amino acid chain, or polypeptide. It occurs in cytoplasm of the bacteria and proceeds in four phases:

1. **Initiation:** The ribosome assembles around the target mRNA. The first tRNA is attached at the start codon of mRNA.
2. **Elongation:** The tRNA transfers an amino acid to the adjacent tRNA, corresponding to the next codon.
3. **Translocation:** The ribosome then moves (translocates) to the next mRNA codon to continue the process, creating an amino acid chain.
4. **Termination:** When a stop codon is reached, the ribosome releases the polypeptide.

PLASMID

Plasmids are the extrachromosomal ds circular DNA molecules that exist in free state in the cytoplasm of bacteria (Fig. 6.4A) and also found in some yeasts.

- Not essential: Plasmids are not essential for life; bacteria may gain or lose plasmid during their lifetime.
- Numbers: They may be present singly or in multiple numbers—up to more than 40 plasmids per cell.
- Independent replication: Plasmids are capable of replicating independently. They can behave as replicon, possessing an origin of replication and other genes that help in replication.
- Episome: Sometimes, the plasmid may integrate with chromosomal DNA of bacteria and such plasmids are called as episomes. They replicate along with bacterial chromosome (Fig. 6.4B).
- Curing: The process of eliminating the plasmids from bacteria is known as curing. It may occur spontaneously or may be induced by treatment of the host cells with substances that inhibit plasmid replication without affecting the host cell, such as acridine, radiations, thymine starvation, and growth at higher temperatures.



Figs 6.4A and B: Plasmids

Classification of Plasmids

Plasmids can be classified in many ways:

1. **Based on ability to perform conjugation:**
   - Conjugative plasmids: Some plasmids have an ability to transfer themselves to other bacteria by means of conjugation. These are called self transmissible or conjugative plasmids.
   - Non-conjugative plasmids: There are also called as nontransmissible plasmids. They cannot transfer themselves.
2. **Based on compatibility between the plasmids**, they can be grouped into:
   - Compatible plasmids: Different plasmids can exist in a single bacterial cell only if they are compatible to each other.
   - Incompatible plasmids: If two plasmids are not compatible, one or the other will be rapidly lost from the cell. They normally share the same replication or partition mechanisms, hence compete with each other.
3. **Based on function**, there are five main classes of plasmids:
   - **Fertility or F-plasmids:** They contain *tra*-genes, which code for the expression of sex pili that help in bacterial conjugation by forming the conjugation tube.
   - **Resistance (R) plasmids**: They contain genes that code resistance to various antibiotics.
   - **Col plasmids:** They contain genes that code for bacteriocins (antibiotic-like protein substances produced by bacteria that can kill other bacteria).
   - **Virulence plasmids:** They code for certain virulence factors and toxins that help in bacterial pathogenesis. Examples include:
     - Heat labile and heat stable toxin of *E. coli*
     - Siderophore production
     - Adherence antigens (K88 plasmid in *E. coli*)
   - **Metabolic plasmids:** They enable the host in various metabolic activities:
     - Digestion of unusual substances, e.g. toluene and salicylate, camphor, etc.
     - Urease synthesis
     - Nitrogen fixation

Plasmid as Vector

Plasmids by their ability to transfer DNA from one cell to another, they have become important vectors in genetic engineering. Plasmids contain certain sites where genes can be inserted artificially by recombinant DNA technology. Such plasmids can be used for various purposes such as protein production, gene therapy, etc (described later in this chapter).

BACTERIAL VARIATION

There are two types of variations seen in bacteria:

- **Phenotypic variation:** It refers to the variations in the expression of various characters by bacterial cells in a given environment, such as synthesis of flagella, expression of certain enzymes, etc.
- **Genotypic variation:** It is the change in the genetic constitution of an organism; which occurs mostly as a result of mutation.

MUTATION

Definition: Mutation is a random, undirected heritable variation caused by change in nucleotide sequence of the genome of the cell.

Mutation can involve any of the numerous genes present in bacterial chromosome or rarely plasmid. The frequency of mutation ranges from 10^{-2} to 10^{-10} per bacterium per division.

Mutations occur in one of the two ways:

1. **Spontaneous mutations:** Mutations that occur naturally in any dividing cells that arise occasionally without adding any mutagen.
2. **Induced mutations:** : These mutations on the other hand, are as a result of exposure of the organism to a **mutagen**, an agent capable inducing mutagenesis. Examples of mutagens include—
   - Physical agent, e.g. ultraviolet (UV) radiations—cytosine and thymine are more vulnerable to UV rays.
   - Chemical agents, e.g. alkylating agents, 5-bromo-uracil and acridine dyes.

Mutation is a natural event, taking place all the time, in all dividing cells. Most mutants go unrecognized as the mutation may be lethal or may involve some minor functions that may not be expressed. Mutation is best appreciated when it involves a function, which can be readily observed by experimental methods. For example *E.coli* mutant that loses its ability to ferment lactose can be readily detected on MacConkey agar.

Mutation can affect any gene and hence may modify any characteristic of the bacterium, for example:

- Sensitivity to bacteriophages
- Loss of ability to produce capsule or flagella
- Loss of virulence
- Alteration in colony morphology
- Alteration in pigment production
- Drug susceptibility
- Biochemical reactions
- Antigenic structure

The practical importance of bacterial mutation is mainly in the field of drug resistance and the development of live vaccines.

Classification of Mutation Types

Mutations may occur in two ways—

1. Small-scale mutations: They are more commonly seen in bacteria. Examples include (1) point mutations—occur at a single nucleotide, (2) addition or deletion of single nucleotide pair
2. Large-scale mutations occur in chromosomal structure: These include deletion or addition of several nucleotide base pairs or gene duplications.

Various types of mutations observed in bacteria are described in Table 6.1.

Detection and Isolation of Mutants

Mutation can be recognised both by genetic method (gene sequencing) as well as by observing phenotypic changes such as fluctuation test and replica plating method. The carcinogenicity of a mutagen is tested by Ames test.

Fluctuation Test

Fluctuation test demonstrates the spontaneous mutation in bacteria. It was described by Luria and Delbruck (1943).

- It states that when bacterial suspension is subjected to selective pressure by subculturing on to agar plate containing a growth limiting substance (e.g. streptomycin or bacteriophage, etc.), they undergo spontaneous mutation.
- However, the rate of mutation vary widely (some bacteria mutate early, some late) which leads to fluctuations.
- Fluctuations in mutation are wide when small volume sub cultures are made (which leads to more frequent mutations), as compared to large volume subcultures (where the mutations occur less frequently).
- This experiment was not widely appreciated, probably due to the complicated statistical evaluation.

Replica Plating Method

Replica plating method is used to detect auxotrophic mutants; described by Lederberg in 1952. It differentiates between the normal strains from auxotrophic mutants based on their ability to grow in the absence of a particular nutrient on which the mutant is dependent. For example, a lysine auxotroph will grow on lysine-supplemented media but not on a medium lacking lysine.

TABLE 6.1: Types of mutations

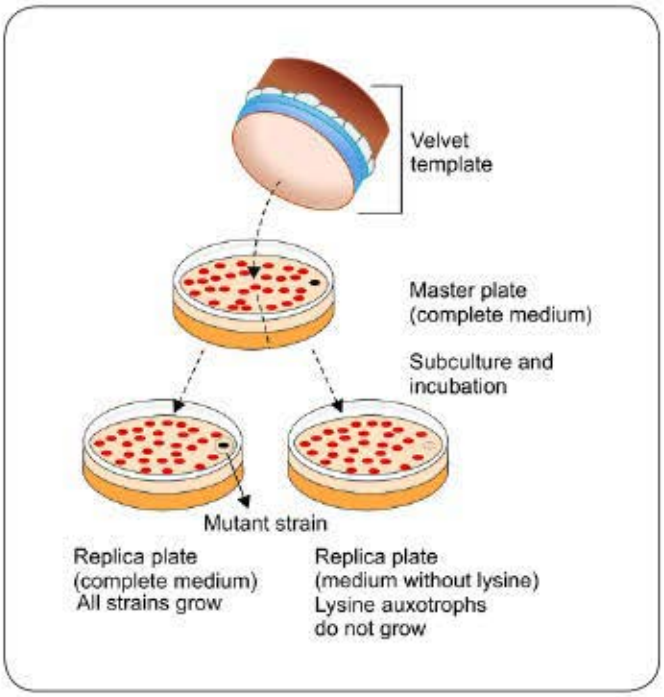
Forward mutations	
Substitutions at single nucleotide base pair	
At DNA Level	
Transition	It is a point mutation that changes a purine nucleotide to another purine (A ↔ G) or a pyrimidine nucleotide to another pyrimidine (C ↔ T)
Transversion	It refers to the substitution of a purine for a pyrimidine or vice versa in DNA, (C/T ↔ A/G)
At codon level	
Silent mutation	The new codon codes for the same amino acid: e.g. AGG ↔ CGG, both code for arginine
Neutral mutation	The new codon forms different but functionally equivalent amino acid: AAA (lysine) AGA (arginine)
Missense mutation	The new codon codes for a different amino acid
Nonsense mutation	The new codon is a stop codon which causes termination, E.g. CAG (Glutamine) ↔ UAG (stop)
Addition or deletion at single or many nucleotide base pairs	
Frame-shift mutation	Any addition or deletion of base pairs that is not a multiple of three results in a shift in the normal reading frame of the coded message forming new set of triplet codon. They are usually very deleterious and may lead to synthesis of nonfunctional proteins
Reverse mutations	**It is a second mutation that nullifies the effect of the first mutation and results in gaining back the function of the wild phenotype.**
True reversion	▪ A true reverse mutation converts the mutant nucleotide sequence back to the wild-type sequence. ▪ AAA (Lysine) forward mutation GAA(Glutamine) reverse mutation AAA (Lysine) (wild type) → (mutant) → (wild type)
Equivalent reversion	▪ Second mutation produces a different codon which codes for the same aminoacid of wild type sequence. ▪ UCC (Serine) forward mutation GAA (Cystine) reverse mutation AAA (Serine) (wild type) → (mutant) → (wild type)
Suppressor mutation	It is a second mutation in a different gene that reverts the phenotypic effects of an already existing mutation.

- Using a velvet template, mixture of colonies (some normal strain, some auxotroph mutants) of an organism are transferred from a master plate, onto two subculture plates—one of the plate is lacking a limiting nutritional substance, e.g. lysine.
- After incubation, colonies similar to those on master plate are formed with relative position of all the colonies retained on the subculture plates, except for the lysine auxotroph which do not grow on the media lacking lysine (Fig. 6.5).

Ames Test (Carcinogenicity Testing)

Ames test is used to identify the environmental carcinogens. It was developed by Bruce Ames (1970).

- It is a mutational reversion assay that uses the mutant strains (histidine auxotroph) of *Salmonella* which are subcultured on two agar plates containing small amount of histidine; one of the plate is added with the test mutagen.
- The plates are incubated for 2–3 days at 37°C.
- All of the histidine auxotrophs will grow for the first few hours until the histidine is depleted.



Velvet template
Master plate (complete medium)
Subculture and incubation
Mutant strain
Replica plate (complete medium) All strains grow
Replica plate (medium without lysine) Lysine auxotrophs do not grow

Fig. 6.5: Replica plating method

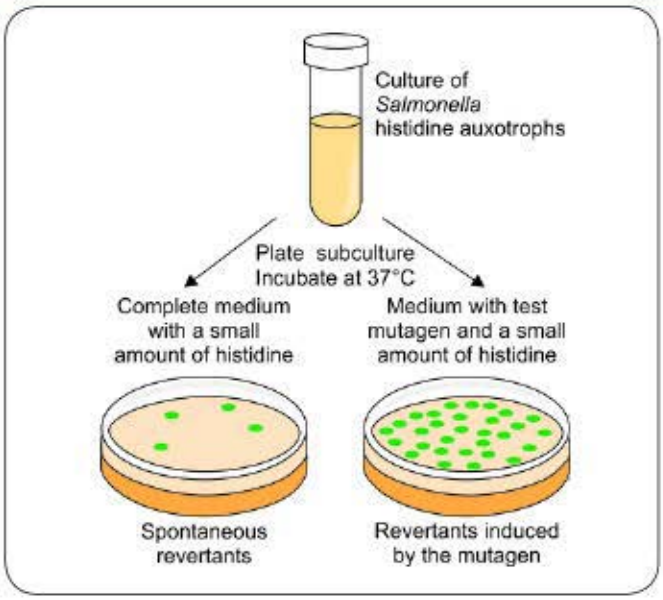


Fig. 6.6: Ames test (carcinogenicity testing)

- Once the histidine supply is exhausted, only revertants that have mutationally regained the ability to synthesize histidine will grow (Fig. 6.6).
- Reversed mutation may be induced due to carcinogen (can affect large number of strains) or occur spontaneously (affect only few strains)
- The relative mutagenicity of the carcinogen can be estimated by counting the colonies—the more colonies, the greater is the mutagenicity.

HORIZONTAL GENE TRANSFER IN BACTERIA

Gene transfer in bacteria can be broadly divided into—

- Vertical gene transfer (transmission of genes from parents to offspring during cell division)
- Horizontal gene transfer (transmission of genes from one bacterium to another neighbour bacterium)

Horizontal gene transfer occurs in bacteria by several methods, such as:

- Transformation (uptake of naked DNA)
- Transduction (through bacteriophage)
- Lysogenic conversion
- Conjugation (plasmid mediated via conjugation tube)

TRANSFORMATION

Definition

Transformation is a process of random uptake of free or naked DNA fragment from the surrounding medium by a bacterial cell and incorporation of this DNA fragment into its chromosome in a heritable form.

Natural transformation has been studied so far only in certain bacteria—*Streptococcus, Bacillus, Haemophilus, Neisseria, Acinetobacter* and *Pseudomonas*.

Mechanism of Transformation

When bacteria lyse, they release large amounts of dsDNA into the surrounding environment. Their uptake depends up on the competency of the bacteria present in the surroundings.

Competency for Transformation

Competent bacteria refers to the cells multiplying in log phase of cell division and expressing certain transformation promoting factors called competence factors.

- Bacteria expressing competence factors (e.g. *S. pneumoniae*) can uptake any DNA fragment irrespective of source.
- But competence factors are not expressed by all bacteria that mediate transformation e.g. *Haemophilus influenzae*. In such case, the uptake of DNA occurs only from the closely related species.

The transformation frequency of very competent cells is around 10^{-3} for most genera. Steps involved in transformation are as follows (Fig. 6.7):

1. A long dsDNA fragment comes in contact with a competent bacterium and binds to DNA-binding protein present on its surface and then it is nicked by a nuclease.
2. One strand is degraded by the recipient cell exonucleases.
3. The other strand associates with a competence specific protein and is internalized, which requires energy expenditure.
4. The single strand enters into the cell and is integrated into the host chromosome in place of the homologous region of the host DNA.

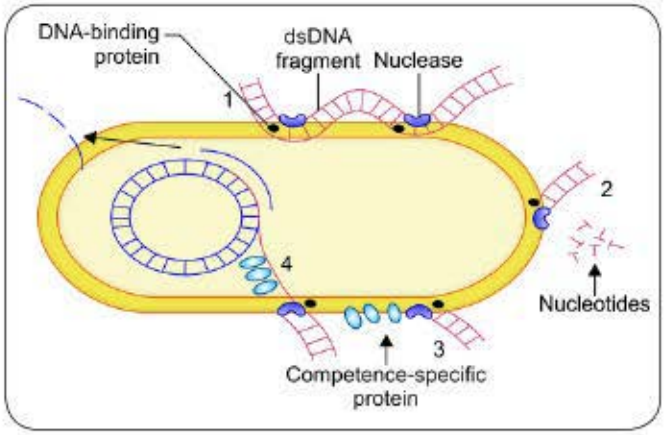

Fig. 6.7: Transformation

1 Heat-killed encapsulated bacteria injected into mouse
2 Mouse remained healthy
1 Living non-encapsulated and heat-killed encapsulated bacteria injected into mouse
2 Mouse died

Fig. 6.8: Griffith experiment demonstrating transformation

Griffith Experiment

The famous Griffith experiment (1928) on mice using pneumococci strains provided the direct evidence of existence of transformation.

- Griffith found that mice died when they were injected with a mixture of live noncapsulated pneumococci and heat killed capsulated pneumococci strains. However, neither of which separately proved fatal to mice (Fig. 6.8).
- He stated that the live noncapsulated strains were transformed into the capsulated strains due to transfer of the capsular genes released from the lysis of the killed capsulated strains, which was confirmed later by Avery, Macleod and McCarty in 1944.

TRANSDUCTION

Definition

Transduction is defined as transmission of a portion of DNA from one bacterium to another by a bacteriophage (bacteriophage is a virus that infects and multiplies inside the bacterium).

Mechanism of Transduction

During the transmission of bacteriophages from one bacterium to other, a part of the host DNA may accidentally get incorporated into the bacteriophage and then gets transferred to the recipient bacterium. This leads to acquisition of new characters by the recipient bacterium coded by the donor DNA.

Bacteriophages perform two types of life cycle inside the host bacteria.

1. **Lytic or virulent cycle:** Bacteriophage multiplies in host cytoplasm, produces large number of progeny phages, which subsequently, are released causing death and lysis of the host cell.
2. **Lysogenic or temperate cycle:** In contrast to virulent cycle, here the host bacterium is unharmed. The phage DNA remains integrated with the bacterial chromosome as the prophage, which multiplies synchronously with bacterial DNA. However, when the phage DNA tries to come out, it is disintegrated from host chromosome, comes out into the cytoplasm, and behaves as a lytic phage. It replicates to produce daughter phages, which are subsequently released by host cell lysis.

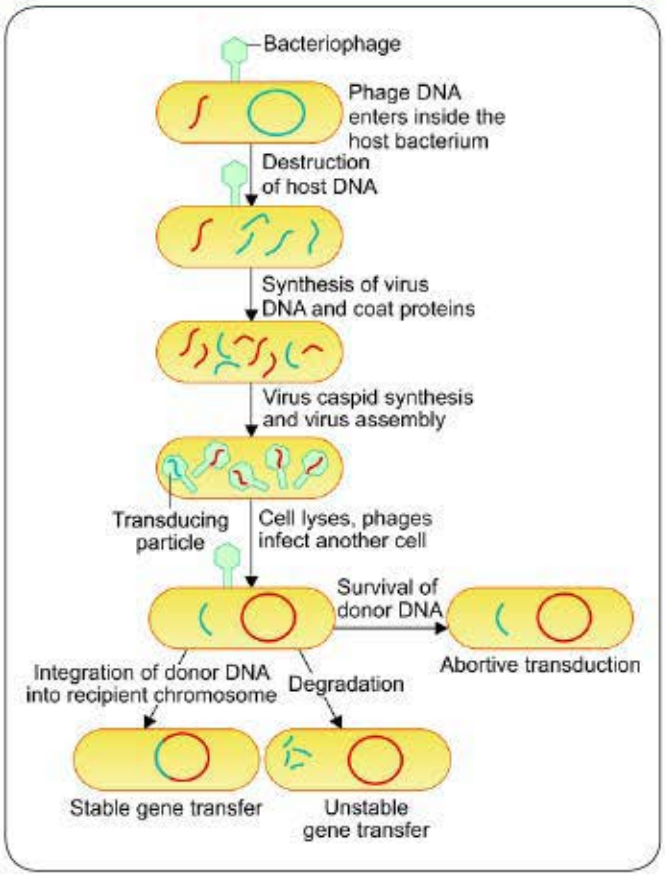
Types of Transduction

Transduction is of two types, either generalized or restricted.

Generalized Transduction

It involves transfer of any part of the donor bacterial genome into the recipient bacteria. Generalized transduction usually occurs as a result of defective assembly during the lytic cycle of virulent and some temperate phages.

- Packaging errors may happen occasionally due to defective assembly of the daughter phages. Instead of their own DNA, a part of host DNA may accidentally be incorporated into the daughter bacteriophages.
- The resulting bacteriophage (called transducing phage) often injects the donor DNA into another bacterial cell but does not initiate a lytic cycle as the original phage DNA is lost.
- The donor DNA may have three fates inside the recipient bacterium (Fig. 6.9):
  - **Abortive transduction:** About 70–90% of the transferred DNA is not integrated with the recipient bacterial chromosome, but often is able to survive and express itself. Such bacteria containing this non-integrated, transduced DNA are called abortive transductants.



Bacteriophage
Phage DNA enters inside the host bacterium
Destruction of host DNA
Synthesis of virus DNA and coat proteins
Virus caspid synthesis and virus assembly
Transducing particle
Cell lyses, phages infect another cell
Survival of donor DNA
Abortive transduction
Integration of donor DNA into recipient chromosome
Degradation
Stable gene transfer
Unstable gene transfer

Normal bacterial cell
Integration as prophage
Crossover to integrate bacterial genes
Bacterial chromosome containing both virus and donor DNA
Bacterial chromosome containing donor DNA

Fig. 6.10: Restricted transduction

- **Stable gene transfer:** The donor DNA gets integrated with recipient bacterial chromosome.
- **Unstable gene transfer:** In some cases, the donor DNA gets disintegrated by the host call enzymes.

Restricted or Specialized Transduction

In contrast to generalized transduction, the restricted transduction is capable of transducing only a particular genetic segment of the bacterial chromosome that is present adjacent to the phage DNA.

It occurs as a result of defect in the disintegration of the lysogenic phage DNA from the bacterial chromosome.

- Restricted transduction has been studied intensively in the 'lambda' phage of *E. coli*.
- When a prophage (i.e. lysogenic bacteriophage is integrated with the bacterial chromosome) leaves the host chromosome, portions of the bacterial chromosome present adjacent to the phage DNA may get wrongly excised along with it.
- Such transducing phages carrying a part of bacterial DNA in addition to their own DNA, when infect another bacterium, the transfer of the donor DNA takes place in two ways (Fig. 6.10).
  - Crossover between the donor DNA and a part of recipient DNA—leads to integration of the donor DNA into the recipient chromosome and a part of recipient DNA into the phage DNA.
  - The entire transducing genome (i.e. phage DNA + donor DNA) acts as a prophage and gets integrated to the recipient chromosome. This occurs if the recipient bacterium is already infected by another helper bacteriophage.

Role of Transduction

In addition to chromosomal DNA, transduction is also a method of transfer of episomes and plasmids.

- **Drug resistance:** Transduction may be a mechanism for the transfer of bacterial genes coding for drug resistance; for example, plasmid coded penicillin resistance in staphylococci.
- **Treatment:** Transduction has also been proposed as a method of genetic engineering in the treatment of some inborn metabolic defects.

LYSOGENIC CONVERSION

During the temperate or lysogenic life cycle, the phage DNA remains integrated with the bacterial chromosome as prophage, which multiplies synchronously with the bacterial DNA.

- The prophage acts as an additional chromosomal element which encodes for new characters and is transferred to the daughter cells. This process is known as lysogeny or lysogenic conversion.
- **Imparts toxigenicity to the bacteria:** Phage DNA may be responsible for bacterial virulence by coding for their toxins production. For example, in *Corynebacterium diphtheriae*, the diphtheria toxin is coded by a lysogenic phage DNA which is integrated with the bacterial chromosome. Elimination of the phage from a toxigenic strain renders the bacterium nontoxigenic.

Phage Coded Toxins

- Bacterial toxins that are coded by lysogenic phages include
  - Diphtheria toxin
  - Cholera toxin
  - Verocytotoxin of *E. coli*
  - *Streptococcus* pyrogenic exotoxin (SPE)— A and C
  - Botulinum toxin C and D

- In lysogenic conversion, the phage DNA itself behaves as the new genetic element, in contrast to transduction where the phage acts only as a vehicle carrying bacterial genes.

CONJUGATION

Conjugation refers to the transfer of genetic material from one bacterium (donor or male) to another bacterium (recipient or female) by mating or contact with each other and forming the conjugation tube. It was discovered first by Lederberg and Tatum (1946).

F^+ X F^- Mating

The F+ cell (also called as the donor or the male bacterium) contains a plasmid called as F factor or fertility factor. The bacteria lacking the F factor are called as female or recipient bacteria or F^- cell.

- F factor is a conjugative plasmid; carries genes that encode for the formation of sex pilus (that helps in conjugation) and self plasmid transfer.
- The F pilus brings the donor and nearby recipient cells close to each other and form a conjugation tube that bridges between the donor and recipient cells (Fig. 6.11A).
- During conjugation, the plasmid DNA replicates by the rolling-circle mechanism, and a copy moves to the recipient bacterium through the conjugation tube. Then, in the recipient, the entering strand is copied to produce complete F factor with ds DNA.
- As a result, recipient (F^-) becomes (F^+) cell and can in turn conjugate with other (F^-) cells. Therefore, it is said that this character of maleness (F^+) in bacteria is transmissible or infectious.
- During F^+ X F^- conjugation, chromosomal genes from donor bacterium may rarely be transferred along with F factor. Here, though the donor chromosomal gene may undergo recombination with the recipient chromosome; but with a lower frequency.

HFR Conjugation

F factor being a plasmid, it may integrate with bacterial chromosome and behave as episome.

- Such donor cells are able to transfer chromosomal DNA to recipient cells with high frequency in comparison to F^+ cells, therefore, named as HFr cells (high frequency of recombination).
- During conjugation of HFr cell with an F^- cell, only few chromosomal genes along with a part of the F factor get transferred. Connection between the cells usually breaks before the whole genome is transferred.
- As the entire F factor does not get transferred, hence following conjugation, F^- recipient cells do not become F^+ cells (Fig. 6.11B).

F' Conjugation

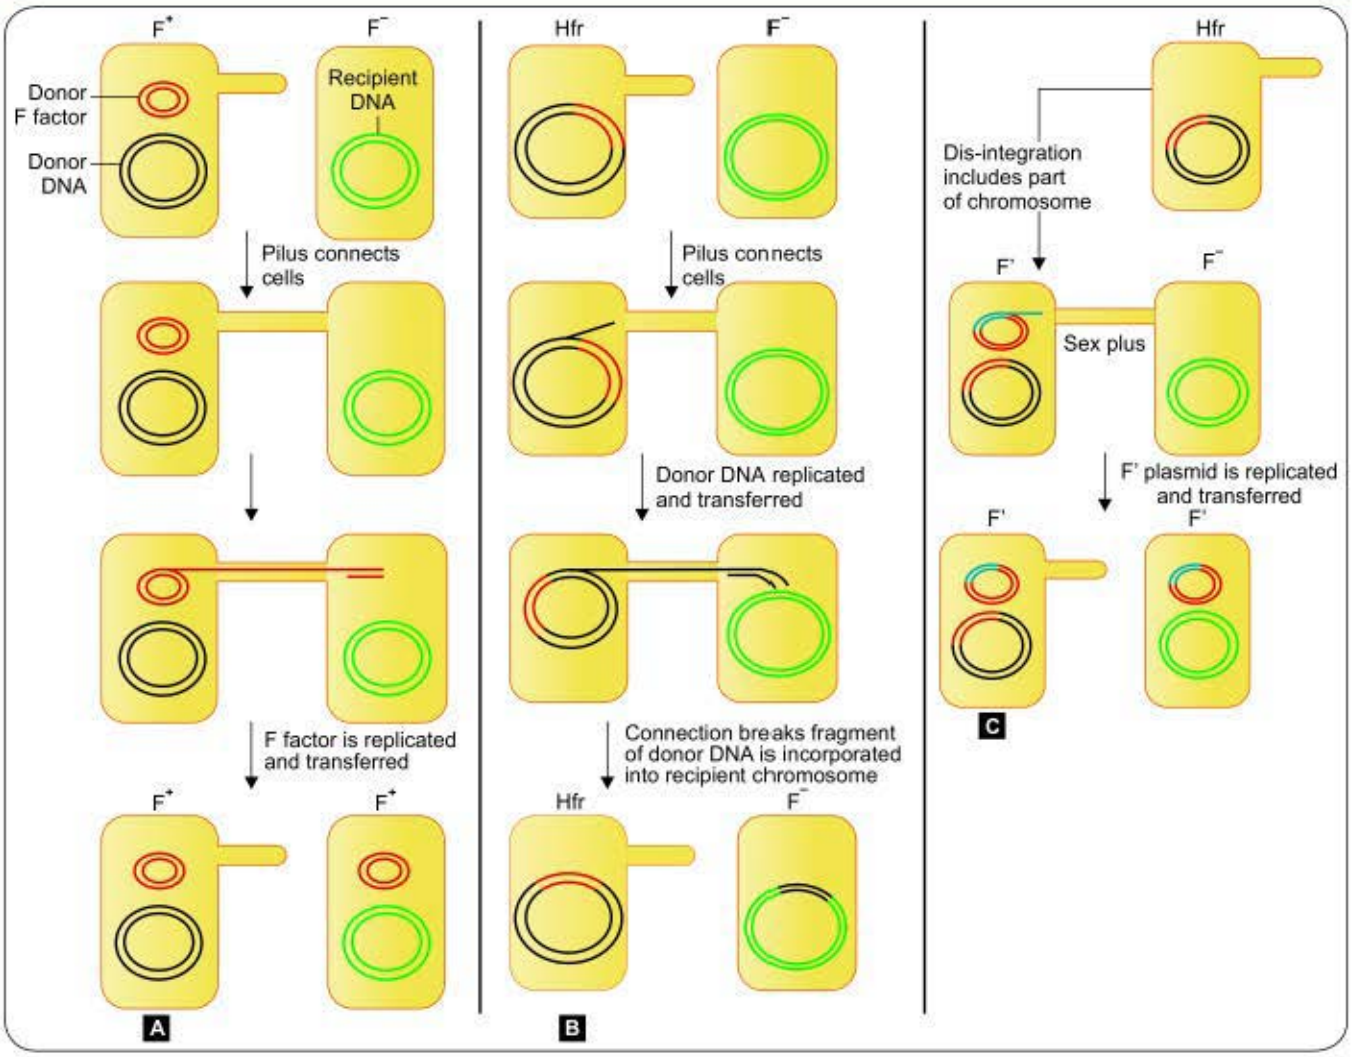
The conversion of a F^+ cell into a Hfr cell is reversible.

- When the F factor reverts from the integrated to free-state, it may sometimes carry with it some chromosomal DNA from adjacent site of its attachment. Such an F factor carrying some chromosomal DNA is named as F' factor (F prime factor).
- When F' cell conjugates with a recipient (F^-), it transfers the host DNA incorporated with it along with the F factor. The recipient becomes F' cell. This process is called sexduction (Fig. 6.11C).

Conjugation plays an important role in the transfer of plasmids coding for antibacterial drug resistance [resistance transfer factor (RTF), see the box in the proceeding text] and bacteriocin production [Colicinogenic (Col) factor].

Colicinogenic (Col) Factor

The bacteriocin production in bacteria is plasmid coded which may be transferred by conjugation. Such plasmids are called as the col factors. Bacteriocins are the antibiotic-like substances produced by one bacterium that inhibit other bacteria. Bacteriocins produced by coliform bacteria are called as colicin. Bacteria other than coliforms also produce similar kind of substances e.g. pyocin by *Pseudomonas*, diphthericin by *Corynebacterium diphtheriae*.



Figs 6.11A to C: Bacterial conjugation. **A.** F^+ X F^- mating; **B.** Hfr X F^- mating; **C.** F' X F^- mating

Resistance Transfer Factor (RTF)

Conjugation is also an important method of transfer of plasmids coding for multiple drug resistance among bacteria.

- R factor (or the resistance factor) is a plasmid which has two components. (R factor = RTF+ r determinants).
  - Resistance transfer factor (RTF): It the plasmid responsible for conjugational transfer (similar to F factor)
  - Resistance determinant (r): R factor can have several r determinants and each r determinant coding for resistance to one drug.
- Sometimes, the R factor dissociates and both RTF and the r determinants exist as separate plasmids. In such cases, the resistance is not transferable though the host cell remains drug resistant.
- In addition to r determinants, the RTF can also attach to other genes; for example, genes coding for enterotoxin and hemolysin production in some enteropathogenic *E.coli*.

Mutational and transferrable drug resistance have been discussed in Chapter 7.

Fate of the Donor DNA Following Horizontal Transfer

Following horizontal gene transfer by any of the methods described above, the donor DNA enters inside the recipient cell, and remains in the cytoplasm temporarily. At this stage, the recipient cell is called **merozygote**. The donor DNA has one of the following fate inside the recipient cell (Fig. 6.12).

- **Recombination:** The donor DNA integrates with the recipient chromosome either as a replacement piece (usually occurs in transformation) or as an extrapiece.
- **Partially diploid cells:** The donor DNA persists outside the host chromosome and the host cell becomes partially diploid for a portion of the genome that is homologous to the donor DNA. Such cells may or may not replicate to produce a clone of partially diploid cells.

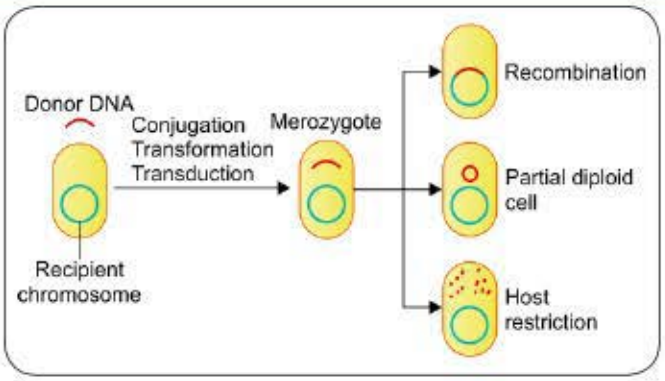


Fig. 6.12: Fate of the donor DNA following horizontal transfer

- **Host restriction:** The host cell nucleases may degrade the donor DNA if it is not homologous to any part of bacterial chromosome.

BACTERIAL RECOMBINATION

Recombination takes place between the donor DNA and recipient chromosome in two ways—general recombination and site specific recombination.

General or Homologous Recombination

It is the most common form, can occur at any place on the recipient's chromosome in general, and occurs between DNA of similar sequences (homologous).

- *Rec genes:* The *rec* genes present in recipient's chromosome and their products, such as the *recA* proteins are crucial to bring out recombination.
- **Crossing-over:** The donor and recipient DNA strands breakage takes place followed by their reunion by crossing-over of strands.
- The **Holliday model** has been put forward (named after Robin Holliday, 1964), to describe the process of reunion.

Reciprocal vs Nonreciprocal General Recombination

Most of the donor DNA fragments entering into the recipient cell by horizontal gene transfer are double stranded; except those transferred by transformation which are single stranded. General recombination can be of two types:

- **Reciprocal exchange:** In most cases (except in transformation), the general recombination usually involves a reciprocal exchange between a pair of homologous DNA sequences between donor and recipient strands.
- **Nonreciprocal exchange:** In bacterial transformation, a nonreciprocal form of general recombination takes place. The single strand of donor DNA is inserted into the host chromosome (by replacing a piece of host chromosome) to form a stretch of heteroduplex DNA.

Site Specific Recombination

In restricted transduction, the integration of bacteriophage DNA into bacterial chromosome is site-specific.

- The donor DNA is not homologous with the chromosome it joins, and
- The enzymes responsible for this event are specific for the particular bacteriophage and its host bacterium.

TRANSPOSITION

Transposons or transposable elements are the bacterial genes that are capable of intracellular transfer between chromosome to chromosome, plasmid to plasmid, and chromosome to plasmid or vice versa and the process of such intracellular transfer of transposons is called as transposition. As transposons move around the genome in a cut-and-paste manner, they are also called **jumping genes** or **mobile genetic elements**.

- Transposition does not require any DNA homology between transposon and the site of insertion. It is, therefore, different from recombination.
- Unlike plasmids, transposons are not self replicating and are dependent on chromosomal or plasmid DNA for replication.
- Transposons were first discovered in the 1940s by Barbara McClintock during her studies on maize genetics for which she won the Nobel prize in 1983.
- Transposons are also discovered in the virus and in eukaryotic genome.

Types of Transposons

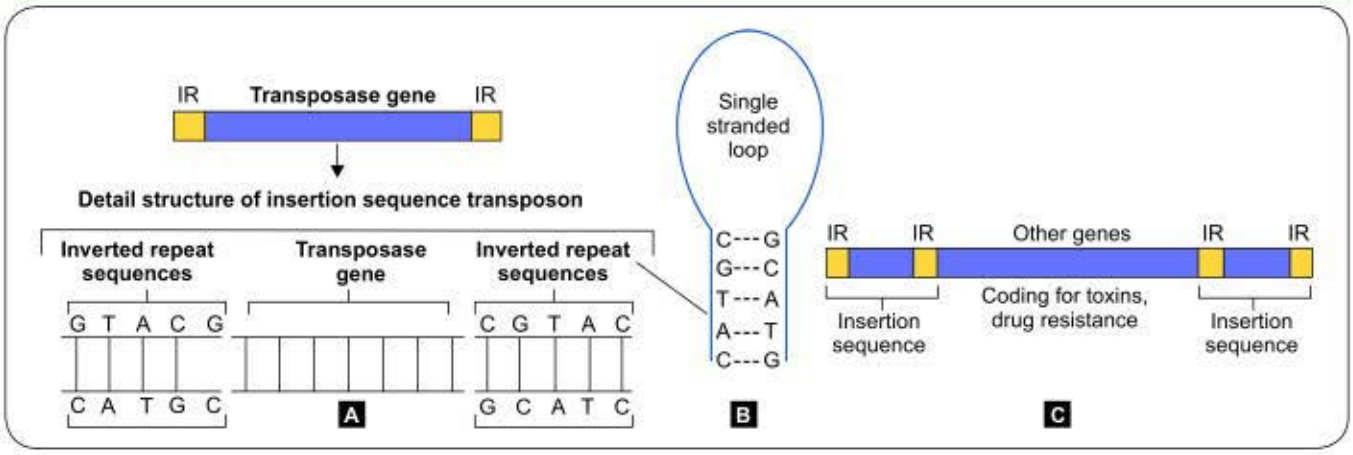
Insertion Sequence Transposon

The simplest form of transposon is an insertion sequence. It is about 1–2 kilo basepairs (kbp) in length and consists of a **transposase gene** (that helps in transposition) which is flanked at both the ends by **inverted repeat sequences** of nucleotides, i.e. nucleotide sequences complementary to each other but in the reverse order (Figs 6.13A and B).

Because of this feature, each strand of the transposon can form a single-stranded loop carrying the transposase gene, and a double stranded stem formed by hydrogen bonding between the terminal inverted repeat sequences.

Composite Transposon

They are larger transposons carrying additional genes, such as genes coding for antibiotic resistance or toxin production in the center and both the ends are flanked by insertion sequences that are identical or very similar in sequence (Fig. 6.13C).



Figs 6.13A to C: Transposons. **A.** Insertion sequence transposon; **B.** Hairpin loop structure of transposons; **C.** Composite transposon

GENE TRANSFER BY ARTIFICIAL METHODS

GENETIC ENGINEERING

Genetic engineering refers to deliberate modification of an organism's genetic information by directly altering its nucleic acid genome. Genetic engineering is accomplished by a precise mechanism known as recombinant DNA technology.

The gene coding for any desired protein is isolated from an organism, and then inserted into suitable vector, which is then cloned in such a way that it can be expressed in the formation of specific (desired) protein.

Recombinant DNA Technology

The procedure of recombinant DNA technology involves the following steps:

1. **Treatment with restriction enzyme:** The DNA from the microorganism is extracted and then is cleaved by enzymes called restriction endonucleases to produce mixture of DNA fragments.
2. **Southern blot:** The fragment containing the desired gene is isolated from the mixture of DNA fragments. This is done by:
   - Electrophoresis: DNA fragments are electrophoretically separated by subjecting to agar gel electrophoresis.
   - Transfer to nitrocellulose membrane: The separated DNA fragments are transferred from the gel to a nitrocellulose membrane.
   - Detection of desired gene: The DNA fragment containing the desired gene is detected adding a specific DNA probe, complementary to the gene of interest.
   - Isolation: The band containing the desired gene is isolated by DNA extraction and then, is subjecting to electrophoresis in a different gel.
3. **Recombination with a vector:** The isolated DNA fragment is annealed with a vector by DNA ligase enzyme.
4. **Introduction of the vector into bacteria:** The vector is introduced into bacteria usually by transformation (injecting by electroporation) and rarely by phage vector by transduction.
5. **Cloning:** Culture of the bacteria containing the desired gene followed by expression of the gene products yields a large quantity of desired protein.

Applications of Genetic Engineering

- **Production of vaccines:** Preparation of certain vaccines is done by DNA recombination technology by producing the desired antigen that can be used as immunogen in vaccine, against which the protective antibody will be produced, e.g. vaccines for hepatitis B and human papilloma virus.
- **Production of antigens used in diagnostic kits:** The antigens used in diagnostic techniques for antibody detection (e.g. ELISA) are prepared by DNA recombinant technology.
- **Production of proteins used in therapy:** Genetic engineering has also been used for the production of proteins of therapeutic interest. These include human growth hormone, insulin, interferons, interleukin-2, tumor necrosis factor, and factor VIII.
- **Transgenic animals:** Recombinant DNA technology can be used to artificially introduce a foreign DNA into the genome of animals. The process is called transfection and the recombinant animals produced in this way are named transgenic or genetically modified

organisms. Transgenic mice are available for a variety of biotechnological applications.

- **Gene therapy:** Genetic diseases can be cured by replacing the defective gene by introducing the normal gene into the patient.

Vector

A vector is a small piece of DNA, into which a foreign DNA fragment can be inserted and that can be stably maintained in an organism and used for cloning purposes. There are four major types of vectors, such as:

- Plasmids
- Bacteriophages
- Cosmids
- Artificial chromosomes, such as bacterial/yeast artificial chromosomes

NUCLEIC ACID PROBE

Nucleic acid probes are radiolabeled or fluorescent labeled pieces of single stranded DNA or RNA, which can be used for the detection of homologous nucleic acid by hybridization.

- Hybridization is the technique in which two single-strands of nucleic acid come together to form a stable double stranded molecule.
- There are two types of nucleic acid probes—DNA probes (hybridizes with DNA) and RNA probes (hybridizes with RNA)

Nucleic acid probes are used to detect the specific nucleic acid either—

- Directly in the clinical sample or
- Following amplification of small quantity nucleic acid present in the clinical sample (e.g. in real time PCR) or
- Following enzymatic digestion of the extracted nucleic acid—so that it detects only the specific DNA fragment from the mixture (e.g. in Southern blot).

BLOTTING TECHNIQUES

A blot, in molecular biology refers to a method of transferring DNA , RNA, or proteins, from gel onto a carrier (e.g. nitrocellulose membrane), followed by their detection by using specific nucleic acid probes (for DNA or RNA detection) or enzyme immunoassay (for protein detection). There are various blotting techniques:

- Southern blot is used to detect DNA
- Northern blot is used to detect RNA
- Western blot is used to detect proteins
- Eastern blot: It is a modification of Western blot, used to analyze proteins for post-translational modifications using probes that may detect lipids, carbohydrate, phosphorylation or any other protein modification.

Sothern blotting technique is described above, under genetic engineering. The methodology of Northern blot is similar to Southern blot, but uses a RNA probe to detect the specific RNA fragment. Western blot is described in Chapter 12.

EXPECTED QUESTIONS

I. Essay:

1. Name various methods of horizontal gene transfer? Discuss in detail about mechanism of conjugation.

II. Write short notes on:

1. Transformation
2. Mutation
3. Transposition
4. Transduction
5. Plasmid

III. Multiple Choice Questions (MCQs):

1. **Mechanism of direct transfer of free DNA:**
   a. Transformation
   b. Conjugation
   c. Transduction
   d. Transposition
2. **Phage mediated transfer of DNA from one bacterium to another bacterium is known as?**
   a. Transformation
   b. Transduction
   c. Transmission
   d. Conjugation
3. **Northern blotting is used for separation of?**
   a. DNA
   b. RNA
   c. Proteins
   d. None
4. **Horizontal transmission of 'R' factor is by:**
   a. Transduction
   b. Transformation
   c. Conjugation
   d. Fusion
5. **F factor carrying some chromosomal DNA is called as:**
   a. F factor
   b. Hfr
   c. RTF
   d. F' factor

Answers

1. a **2.** b **3.** b **4.** c **5.** d

CHAPTER 7

Antimicrobial Agents, Antimicrobial Resistance and Antimicrobial Susceptibility Testing

Chapter Preview

- Antimicrobial agents
- Antimicrobial resistance
  - Intrinsic and acquired
  - Mutational and transferable
  - Mechanism of resistance
- Antimicrobial susceptibility testing
  - Disk diffusion method
  - Dilution tests
  - Other methods

ANTIMICROBIAL AGENTS

Antimicrobials are the agents that kill or inhibit the growth of microorganisms.

Classification

Antimicrobial agents are classified in various ways:

1. According to microorganisms against which they are used—antibacterial, antifungal, antiparasitic, antiviral agents, etc.
2. According to their ability to kill (ends with suffix cidal) or inhibit (ends with suffix static) the microorganism, e.g. bactericidal and bacteriostatic.
3. According to the source:
   - Antibiotics: These are natural substances, produced by certain groups of microorganisms.
   - Chemotherapeutic agents: These agents are chemically synthesized.
4. According to their site of action and usage:
   - Disinfectants destroy a wide range of microbes on non-living surfaces to prevent their spread.
   - Antiseptics (which are applied to the living tissues and help to reduce infection during surgery), and
   - Antibiotics (which destroy microorganisms within the body).
5. According to the chemical structure and mechanism of action—the antimicrobial agents can be further divided into many classes, as described in Table 7.1.

Though incorrect, the word 'antibiotics' is loosely used to describe antimicrobial agents.

ANTIMICROBIAL RESISTANCE

Antimicrobial resistance refers to development of resistance to an antimicrobial agent by a microorganism. It can be of two types— acquired and intrinsic.

Acquired Resistance

This refers to the emergence of resistance in bacteria that are ordinarily susceptible to antimicrobial agents, by acquiring the genes coding for resistance. Most of the antimicrobial resistance shown by bacteria belong to this category.

The emergence of resistance is a major problem worldwide in antimicrobial therapy. Infections caused by resistant microorganisms often fail to respond to the standard treatment, resulting in prolonged illness, higher healthcare expenditures, and a greater risk of death.

- Overuse and misuse of antimicrobial agents is the single most important cause of developme85nt of acquired resistance.
- The evolution of resistant strains is a natural phenomenon, which can occur among bacteria especially when an antibiotic is over used.
- Use of the particular antibiotic poses selective pressure in a population of bacteria which in turn promotes resistant bacteria to thrive and the susceptible bacteria to die off (Fig. 7.1).
- Thus the resistant bacterial populations flourish in areas of high antimicrobial use, where they enjoy a selective advantage over susceptible populations.
- The resistant strains then spread in the environment and transfer the genes coding for resistance to other unrelated bacteria.

Other factors favouring the spread of antimicrobial resistance include—

- Poor infection control practices in hospitals- e.g. poor hand hygiene practices can facilitate transmission of resistant strains.
- Inadequate sanitary conditions.
- Inappropriate food-handling.
- Irrational use of antibiotics by doctors, not following antimicrobial susceptibility report.
- Uncontrolled sale of antibiotics over the counters without prescription.

TABLE 7.1: Antimicrobial agents—classification, indication, and mechanism of resistance

Class/mechanism	Drugs	Spectrum of activity	Resistance
A. Inhibit Cell Wall Synthesis			
β-Lactam Antibiotics (Bactericidal: block cross linking via competitive inhibition of the transpeptidase enzyme i.e. penicillin binding protein)			
Penicillins			
Penicillin	Penicillin G Aqueous penicillin G Procaine penicillin G Benzathine penicillin G Penicillin V	Mostly gram-positive bacteria: ▪ *Streptococcus pyogenes* ▪ Pneumococcus ▪ *Corynebacterium diphtheriae* (diphtheria) ▪ *Clostridium tetani* (tetanus) ▪ *Clostridium perfringens* (gas gangrene)	1. **Drug inactivation** (by producing β-lactamase enzyme): Seen in both gram-positive and gram-negative bacteria
		▪ Meningococcal infection ▪ Gonococcus (resistance has been reported) ▪ *Treponema pallidum* (syphilis)	2. **Alteration of target site-PBP** (penicillin-binding protein) is altered to PBP2a, seen in gram-positive bacteria 3. **Decreased permeability** as in gram-negative bacteria- due to altered outer-membrane porins.
Penicillinase-resistant-penicillins	Methicillin, cloxacillin, oxacillin, dicloxacillin	**Same as penicillin *plus*** Penicillinase producing *Staphylococcus aureus*	
Aminopenicillins (extended spectrum)	Ampicillin Amoxicillin	**Same as penicillin *plus*** ▪ *Enterococcus faecalis* ▪ *Escherichia coli, Klebsiella* ▪ *Helicobacter pylori* ▪ *Salmonella* (resistance reported) ▪ *Shigella* (bacillary dysentery)	
Antipseudomonal penicillins	Carbenicillin Ticarcillin, piperacillin	**Same as aminopenicillins *plus*** *Pseudomonas aeruginosa*	
β lactam + β lactamase inhibitors	Aminopenicillins or antipseudomonal penicillins plus ▪ Clavulanic acid ▪ Sulbactam, tazobactam	Same as aminopenicillins or anti-pseudomonal penicillins spectrum plus β lactamase producing bacteria	
Cephalosporins			
1st generation	Cefazolin Cephalexin	▪ *Staphylococcus aureus* ▪ *Staphylococcus epidermidis* ▪ Some gram-negative bacteria like *Escherichia coli* and *Klebsiella*	
2nd generation	Cefoxitin Cefaclor Cefuroxime	▪ Same as 1st generation *plus* ▪ ↑ Gram-negative activity	
3rd generation	Ceftriaxone Cefotaxime Ceftazidime	▪ Decreased activity against gram-positives compared to the above. ▪ ↑ Gram-negative activity ▪ Some are active against *Pseudomonas* (Ceftazidime)	
4th generation	Cefepime Cefpirome	▪ Good activity against gram-positive and negative bacteria including *Pseudomonas*	
5th generation	Ceftobiprole	▪ Same as 4th generation *plus Pseudomonas* and MRSA (only β lactam to be effective against Methicillin resistant *Staphylococcus aureus, i.e.* MRSA)	
Carbapenems	Imipenem Meropenem Doripenem Ertapenem	▪ Broadest range of activity against most bacteria, which include gram-positive cocci, Enterobacteriaceae, *Pseudomonas, Listeria,* anaerobes like *Bacteroides fragilis* and *Clostridium difficile;* except-MRSA, *Mycoplasma,* etc.	
Aztreonam	Aztreonam	▪ Gram-negative rods	

Contd...

Contd...

Class/mechanism	Drugs	Spectrum of activity	Resistance
Other cell wall inhibitors			
Glycopeptides (bactericidal: disrupt peptidoglycan cross-linkage)	Vancomycin Teicoplanin	Active against most gram-positive bacteria MRSA (drug of choice), and indicated if the patient is allergic to β lactam drugs	Alteration of target (substitution of D-alanine D-alanine side chain peptidoglycan)
Polymyxins	Polymyxin B (topical) Colistin or Polymyxin E (topical and systemic use)	Gram-negative infections (disrupt both the outer and inner membranes in gram-negative cell wall)	Not defined
Bacitracin	Bacitracin	Topical gram-positive cocci infections	Not defined
B. Protein Synthesis Inhibition			
Anti-30S ribosomal subunit			
Aminoglycosides (bactericidal: irreversible binding to 30S)	Gentamicin Neomycin Amikacin Tobramycin Streptomycin	Aerobic gram-negative bacteria, such as—Enterobacteriaceae and some are active against *Pseudomonas* (gentamicin and amikacin) Often used for empirical therapy in adjunct with third generation cephalosporins in respiratory infections, meningitis and subacute bacterial endocarditis	1. Drug inactivation by aminoglycoside-modifying enzyme 2. Decreased permeability through Gram-negative outer membrane 3. Decreased influx of drug
Tetracyclines (bacteriostatic: bind to 30S subunit of ribosome and block tRNA attachment)	Tetracycline Doxycycline Minocycline Demeclocycline	Rickettsiae, Chlamydiae, *Mycoplasma*, Spirochetes *Yersinia pestis, Brucella, Haemophilus ducreyi, Campylobacter, Vibrio cholerae*	1. Decreased intracellular drug accumulation (active efflux) 2. Ribosomal target site alteration
Anti-50S ribosomal subunit			
Chloramphenicol (bacteriostatic: binds to 50S ribosomal subunit and interfere with peptide bond formation)	Chloramphenicol	*Haemophilus influenzae* Pyogenic meningitis Brain abscess Anaerobic infection Enteric fever (*Salmonella*)—not used now due to development of resistance	1. Drug inactivation by producing chloramphenicol acetyltransferase enzyme 2. Altered membrane transport (active efflux)
Macrolides (bacteriostatic: binds 50S ribosomal subunit and prevent translocation of elongated peptide	Erythromycin Azithromycin Clarithromycin	*Streptococcus* *Haemophilus influenzae* *Mycoplasma pneumoniae*	1. Alteration of ribosomal target 2. Active efflux of antibiotic
Linezolid (Inhibitit protein synthesis by binding to 50S)	Linezolid	Resistant gram-positives like MRSA	Alteration of target site
Streptogramins (Inhibit protein synthesis by binding to 50S	Quinupristin Dalfopristin	*Streptococcus pyogenes* and *Staphylococcus aureus* skin infections MRSA infections VRE (Vancomycin resistant enterococci) infections	1. Alteration of target (dalfopristin) 2. Active efflux (quinupristin) 3. Drug inactivation (quinupristin and dalfopristin)
Mupirocin (Inhibits isoleucyl-tRNA synthetase)	Mupirocin	Topical ointment is given for- Skin infections Nasal carriers of MRSA	Mutation of gene for target site protein
C. Nucleic Acid Synthesis Inhibitors			
DNA synthesis inhibitors			
Fluoroquinolones	Inhibit DNA gyrase (A subunit) and topoisomerase IV, thus inhibiting DNA synthesis		
Nalidixic acid		Coliform gram-negative bacilli	1. Alteration of target (mutation of DNA gyrase genes)

Contd...

Contd...

Class/mechanism	Drugs	Spectrum of activity	Resistance
Fluoroquinolones 1st generation	Norfloxacin, ciprofloxacin ofloxacin	**Enterobacteriaceae:**, such as *E.coli, Klebsiella, Enterobacter, Salmonella, Shigella, Proteus, Yersinia*	2. Poor transport across cell membrane
Fluoroquinolones 2nd generation	Levofloxacin, lomefloxacin, moxifloxacin, sparfloxacin	**Others:** *Neisseria, Haemophilus, Campylobacter, Vibrio cholerae, Pseudomonas, Staphylococcus aureus*	
Metronidazole	Intracellularly generates metabolic by-products that damage DNA	Anaerobic organisms	Not defined
RNA synthesis inhibitors			
Rifampin	Inhibits RNA polymerase	*Staphylococcus* *Mycobacterium tuberculosis*	Alteration of target (mutation of *rpoB* gene)
Mycolic acids synthesis inhibitors			
Isoniazid	Inhibits mycolic acid synthesis	Tuberculosis Latent TB	Mutations in enzyme processing isoniazid into active metabolites (KatG enzyme)
Folic acid Synthesis Inhibitors *Bacteriostatic*: Competitively inhibit enzymes involved in two steps of folic acid biosynthesis **PABA**(para-amino-benzoic acid) —Folate synthase / Sulfonamide blocks→ **Dihydrofolic acid** —Dihydrofolate reductase / Trimethoprim blocks→ **Tetrahydrofolic acid**			
Sulfonamides and trimethoprim	Sulfadiazine Sulfacetamide Cotrimoxazole (Trimethoprim + Sulfamethoxazole)	**Sulfadiazine:** Used topically in burn wound surface **Cotrimoxazole** is indicated in: ▪ Urinary tract and respiratory tract infections- Active against *Serratia, Klebsiella, Enterobacter* ▪ *Shigella* dysentery, *vibrio cholerae* ▪ *Toxoplasma gondii, haemophilus ducreyi,* ▪ *Pneumocystis jirovecii*	Production of insensitive targets [dihydropteroate synthetase (sulfonamides) and dihydrofolate reductase (trimethoprim)] that bypass metabolic block
Antimicrobial agents that act on cell membrane			
Gramicidin	Forms pores	Topical use against cocci (gram-positive and negative)	Not defined
Daptomycin	Forms channels that disrupt membrane potential	Bactericidal against gram-positive bacteria including VRE and MRSA	Not defined

Final population of resistant bacteria

Fig. 7.1: Mechanism of development of acquired resistance

Intrinsic Resistance

It refers to the innate ability of a bacterium to resist a class of antimicrobial agents due to its inherent structural or functional characteristics, (e.g. gram-negative bacteria are resistant to vancomycin). This imposes only little threat to the world as very few organisms show intrinsic resistance (Table 7.2).

Mutational and Transferable Drug Resistance

In presence of selective antibiotic pressure, bacteria acquire new genes mainly by two broad methods:

Mutational Resistance

Resistance can develop due to mutation of the resident genes.

TABLE 7.2: Intrinsic antimicrobial resistance

Organism	Intrinsic resistance against
Anaerobic bacteria	Aminoglycosides
Aerobic bacteria	Metronidazole
Gram-negative bacteria	Vancomycin
Klebsiella species	Ampicillin
Pseudomonas	Sulfonamides, trimethoprim, tetracycline or chloramphenicol
Enterococci	Aminoglycosides, all cephalosporins

- It is typically seen in *Mycobacterium tuberculosis*, developing resistance to anti-tubercular drugs.
- Mutational drug resistance differs from transferable drug resistance in many ways (Table 7.3).
- Usually, it is a low level resistance, developed to one drug at a time; which can be overcome by using combination of different classes of drugs.
- That is why multidrug therapy is used in tuberculosis using 4–5 different classes of drugs, such as isoniazid, rifampicin, pyrazinamide, ethambutol and streptomycin.

Transferrable Drug Resistance

In contrast, transferrable drug resistance is plasmid coded and usually transferred by conjugation or rarely by transduction, or transformation (refer Chapter 6).

- The resistance coded plasmid (called R plasmid) can carry multiple genes, each coding for resistance to one class of antibiotic.
- Thus, it results in a high degree of resistance to multiple drugs, which cannot be overcome by using combination of drugs.

TABLE 7.3: Mutational vs transferable drug resistance

Mutational drug resistance	Transferable drug resistance
Resistance to one drug at a time	Multiple drug resistance at the same time
Low-degree resistance	High-degree resistance
Resistance can be overcome by combination of drugs	Cannot be overcome by drug combinations
Virulence of resistance mutants may be lowered	Virulence not decreased
Resistance is not transferable to other organisms but spread to off springs by vertical spread only	• Resistance is transferable to other organisms. • Spread by: Horizontal spread (conjugation, or rarely by transduction/transformation)

Mechanism of Antimicrobial Resistance

Bacteria develop antimicrobial resistance by several mechanisms.

1. Decreased Permeability across the Cell Wall

Certain bacteria modify their cell membrane porin channels; either in their frequency, size, or selectivity; thereby preventing the antimicrobials from entering into the cell. This strategy has been observed in many gram-negative bacteria, such as *Pseudomonas, Enterobacter* and *Klebsiella* species against drugs, such as imipenem, aminoglycosides and quinolones.

2. Efflux Pumps

Certain bacteria possess efflux pumps which mediate expulsion of the drug(s) from the cell, soon after their entry; thereby preventing the intracellular accumulation of drugs. This strategy has been observed in:

- *Escherichia coli* and other Enterobacteriaceae against tetracyclines, chloramphenicol.
- Staphylococci against macrolides and streptogramins.
- *Staphylococcus aureus* and *Streptococcus pneumoniae* against fluoroquinolones.

3. By Enzymatic Inactivation

Certain bacteria can inactivate the antimicrobial agents by producing various enzymes, such as:

- **β lactamase** enzyme production (observed in both gram-positive and gram-negative bacteria): It breaks down the β lactam rings, there by inactivating the β lactam antibiotics (see the highlight box).
- **Aminoglycoside modifying enzymes** like (acetyltransferases, adenyltransferases, and phosphotransferases, produced by both gram-negative and gram-positive bacteria)—they destroy the structure of aminoglycosides.
- **Chloramphenicol acetyl transferase:** It is produced by members of Enterobacteriaceae; it destroys the structure of chloramphenicol.

By Modifying the Target Sites

Modification of the target sites of antimicrobial agent (which are within the bacteria) is a very improtant mechanism. It is obserevd in:

- MRSA (Methicillin-resistant *Staphylococcus aureus*): In these strains, the target site of penicillin i.e. penicillin binding protein (PBP) gets altered to PBP-2a. The altered PBP do not sufficiently bind to β-lactam antibiotics and therefore prevent them from inhibiting the cell wall synthesis. (Described in detail in Chapter 21).
- Streptomycin resistance in *Mycobacterium tuberculosis*: It is due to modification of ribosomal proteins or 16S rRNA.

- Rifampicin resistance in *Mycobacterium tuberculosis*—due to mutations in RNA polymerase.
- Quinolone resistance seen in many gram-positive bacteria, particularly *S. aureus* and *S. pneumoniae*—due to mutations in DNA gyrase enzyme.

Vancomycin resistance in enterococci (VRE): These strains have a change in the target site of vancomycin (i.e. D-alanine D-alanine side chain peptidoglycan) (Chapter 22).

Beta Lactamase Enzymes

β lactamase enzymes are capable of hydrolysing the β-lactam rings (the active site) of β lactam antibiotics; thereby deactivating their antibacterial properties.

- They can be produced by both gram-positive and gram-negative organisms.
- They are plasmid coded, and transferred from one bacterium to other mostly by conjugation, (except in *Staphylococcus aureus* where they are transferred by transduction).

Beta-lactamases can be classified in two ways:

- Ambler's classification (structural or molecular classification): According to this, β lactamases are classified into four classes (Table 7.4)
- Bush Jacoby Medeiros classification or functional (phenotypic) classification: This is the most advanced and complex classification.

TABLE 7.4: Ambler classification of beta lactamases

Class A: Extended spectrum β lactamases (ESBL)
Organisms producing ESBL enzymes are resistant to all penicillins and 1st, 2nd and 3rd generation cephalosporins and monobactam, however remain sensitive to carbapenems and cephamycins. ▪ Resistance can be overcome by use of β lactam along with β lactamase inhibitor (e.g. sulbactum or clavulanic acid) ▪ Detected by-Combination disk test (Ceftazidime and cetftazidime + clavulinic acid), Three dimensional test (best method)
Class B: Metallobetalactamase (MBL)
These organisms are resistant to all those antibiotics to which AmpC beta-lactamase producers are resistant. In addition, they are also resistant to carbapenems. ▪ Resistance cannot be overcome by β lactam + β lactamase inhibitor combination ▪ Detected by EDTA disk synergy test, modified Hodge test
Class C: AmpC beta-lactamase
These organisms are resistant to all those antibiotics to which ESBL producers are resistant plus they are resistant to cephamycins (e.g. cefoxitin and cefotetan). But they are sensitive to carbapenems. Resistance cannot be overcome by β lactam + β lactamase inhibitor combination
Class D: oxacillinase
Resistance can be overcome by β lactam + β lactamase inhibitor combination

ANTIMICROBIAL SUSCEPTIBILITY TESTING

Bacteria exhibit great strain variations in susceptibility to antimicrobial agents. It is, therefore, essential to determine the susceptibility of pathogenic bacteria isolated from the clinical specimens to antibiotics that are likely to be used in the treatment.

Antimicrobial susceptibility test (AST) is performed only for pathogenic bacteria isolated from the specimen, and not for the commensal bacteria (Table 7.5). For example, *E. coli* isolated from urine specimen should be subjected to AST, whereas *E. coli* isolated from stool is a commensal; hence, AST is not performed.

Disk Diffusion Method

Disk diffusion tests are the most widely used method. They are suitable for rapidly growing pathogenic bacteria; however, they are unsuitable for slow growing bacteria.

The disk diffusion method is so named because:

- It uses filter paper disks impregnated with appropriate concentration of the antibiotic solution.
- The test bacterium is inoculated (as lawn culture) on the solid medium and then the antibiotic disks are applied.
- The antibiotic in the disks diffuses through the solid medium, so that the concentration is highest near the site of application of the antibiotic disk and decreases gradually away from it.
- Sensitivity to the drug is determined by the zone of inhibition of bacterial growth around the disk.

Medium (Mueller–Hinton Agar)

Mueller–Hinton agar (MHA) is considered as the best medium to use for routine susceptibility testing of non-fastidious bacteria for the following reasons:

- It shows acceptable batch-to-batch reproducibility for susceptibility testing.
- It supports satisfactory growth of most nonfastidious pathogens.

TABLE 7.5: Classification of antimicrobial susceptibility testing methods

▪ Disk diffusion methods:
  • Kirby–Bauer disk diffusion method
  • Stokes disk diffusion method

▪ Dilution tests:
  • Broth dilution method
  • Agar dilution method

▪ E-test
▪ Automated methods
▪ Molecular methods (PCR detecting drug resistant genes)

- It has minimal inhibitory effect on sulfonamide and trimethoprim. Hence, these antibiotics are better tested in MHA than any other media.

Modifications of MHA

- Lysed horse blood is added to MHA to support the growth of fastidious organisms, such as *H. influenzae*.
- Sodium chloride (2–4% NaCl) should be added to the medium for testing MRSA isolates.

Inoculum

Isolated pure colonies of the test organism are inoculated in a suitable liquid medium (peptone water broth) and incubated at 35–37°C for 4–6 hours.

- The density of the organisms in broth is adjusted to approximately 1.5×10^8 cfu/mL by comparing its turbidity with that of 0.5 McFarland opacity standard tube.
- **Lawn culture:** The broth is then inoculated on the medium by spreading with sterile swabs.
- The ideal inoculum after overnight incubation gives an even semiconfluent growth. Too heavy inoculum reduces the size of inhibition zones.
- **Control strains:** Similar to the test isolate, the inoculum of control strain should also be made and tested for AST. The following ATCC (American Type Culture Collection) strains are used as standard control strains.
  - *Escherichia coli* ATCC 25922
  - *Pseudomonas aeruginosa* ATCC 27853
  - *Staphylococcus aureus* ATCC 25923
  - *Enterococcus feacalis* ATCC 29212

Antibiotic Disk

Antibiotic disks are available commercially or prepared in in-house. Sterile filter paper (Whatman number 1) disks of 6 mm diameter are impregnated with standard quantity of antibiotic solution.

Choice of Antibiotic Disk

It is neither possible nor desirable to test the susceptibility against all the drugs. The panel of the drugs to be tested against an isolate depends upon various factors:

- Antibiotics should likely to be used for therapy.
- Organism against which the drug has to be tested.
- Local prescribing habits of the antimicrobial agents.
- Resistant pattern of the locally prevalent pathogens
- Cost, toxicity, pharmacokinetics, and spectrum of activity of an antimicrobial agent for the management of illness in a particular patient.

First-line and Second-line Drug Testing

- **First-line drugs:** Those antibiotics that are commonly used in a locality with respect to the organism isolated should be tested first. First-line should also include the antibiotic currently being administered to the patient, their spectrum should be relevant to the organism isolated.
- **Second-line drugs** include the panel of those antibiotics for which the prescription is restricted only to special circumstances. They are reserved for testing later if the organism is found to be resistant to all the first-line antibiotics tested before.

Kirby–Bauer Disk Diffusion Method

A cotton swab is dipped into inoculum and squeezed to drain out the excess fluid. Then the swab is inoculated on to the Mueller–Hinton agar plate by streaking the swab three times over the entire agar surface.

- After drying the surface of agar plate for 3–5 minutes the antibiotic disks are applied using either sterile forceps or multidisk dispenser.
- Disks should not be placed closer than 20 mm (center to center) on the MHA plate.
- Ordinarily, maximum up to 6 disks can be applied on a 100 mm plate (five in the periphery and one in the center) (Fig. 7.2).
- The plates are then incubated at 37°C for 16–18 hours. When tested for MRSA, result should be read only after 24 hours of incubation.
- The zones of complete growth of inhibition around each of the disks are measured using a ruler or Vernier caliper. The diameter of the disk is also included in this measurement. (Fig. 7.3)
- The interpretation of zone size into sensitive, intermediate or resistant is based on the standard zone size interpretation chart (Table 7.6).
- Control strains should be tested each time when a new batch of disks or Mueller-Hinton agar is used.

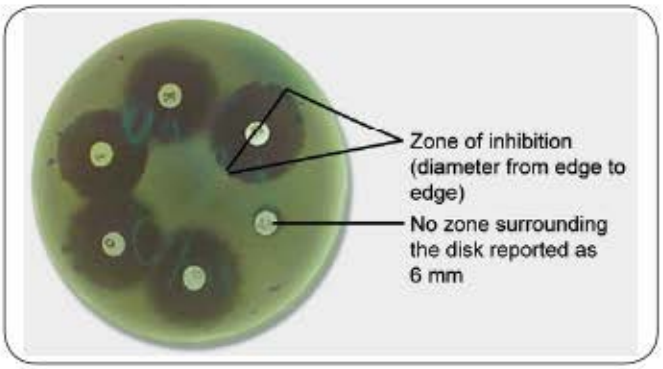

Fig. 7.2: Kirby–Bauer disk diffusion method

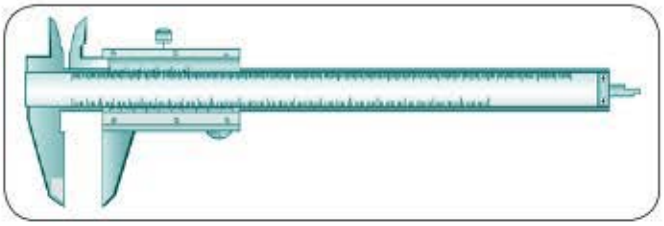

Fig. 7.3: Vernier caliper

TABLE 7.6: Commonly used disk concentrations and interpretation of disk diffusion test

Antimicrobial agents	Disk (µg) strength	Diameter of zone of inhibition (in mm)		
		Resistant	Intermediate	Sensitive
Benzyl penicillin (*S. aureus*)	10 units	≤28	–	≥29
Cefoxitin (*S. aureus*)	30	≤21	–	≥22
Gentamicin (G)	10	≤12	13–14	≥15
Amikacin (Ak)	30	≤14	15–16	≥17
Erythromycin (E)	15	≤13	14–22	≥23
Tetracycline (T)	30	≤14	15–18	≥19
Nitrofurantoin (Nf)	300	≤14	15–16	≥17
Ciprofloxacin (Cf)	5	≤15	16–20	≥21
Ceftriaxone (Ci)	30	≤19	20–22	≥23
Imipenem (I)	10	≤19	20–22	≥23
Vancomycin (for *Enterococcus*)	30	≤14	15–16	≥17

Stokes Disk Diffusion Method

Here, the MHA plate is divided into three parts. The test organism is inoculated on the central one third and the control strain on upper and lower thirds of the plate.

- In modified Stokes disk diffusion method, the test bacterium is inoculated over the upper and lower thirds of the plate and control on central one third.
- An Uninoculated gap of 2–3 mm wide should separate the test and the control area on which the antibiotic disks are applied.
- The plates are then incubated at 37°C for 16–18 hours.

Reporting in Stokes Method

The sensitivity report is prepared by comparing the zones of inhibition of control and test bacterium (Fig. 7.4). The radius of the inhibition zone from the edge of the disk to the edge of the zone is measured. Result is interpreted as follows:

- **Sensitive (S):** Zone radius is wider than or equal to, or not more than 3 mm smaller than the control.
- **Intermediate (I):** Zone radius is >2 mm but smaller than the control by >3 mm.
- **Resistant (R):** No zone of inhibition or zone radius measures 2 mm or less.

Primary Disk Diffusion Test

The primary disk diffusion test may be performed when results are required urgently and single pathogenic bacterium is suspected in the specimen (for sterile fluid). Here, the clinical specimen is directly inoculated uniformly on the surface of a agar plate and the antibiotic disks are applied. The results of the primary test should be verified by testing the isolates subsequently. This test is of no use when mixed growth of different bacteria is suspected to be there in the specimen, e.g. pus, stool, sputum, etc.

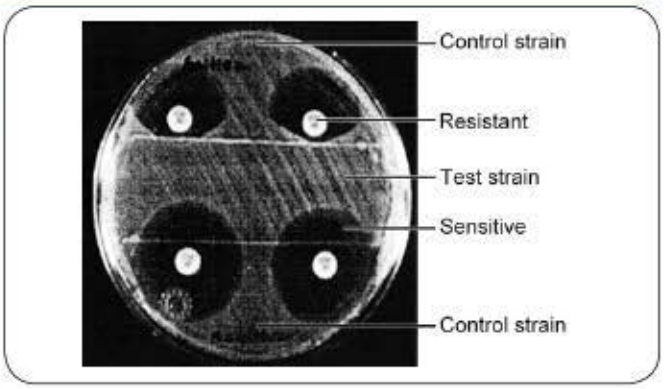

Fig. 7.4: Stokes disk diffusion method

Dilution Tests

Here, the antimicrobial agent is serially diluted, each dilution is tested with the test organism for antimicrobial susceptibility test and the MIC is calculated.

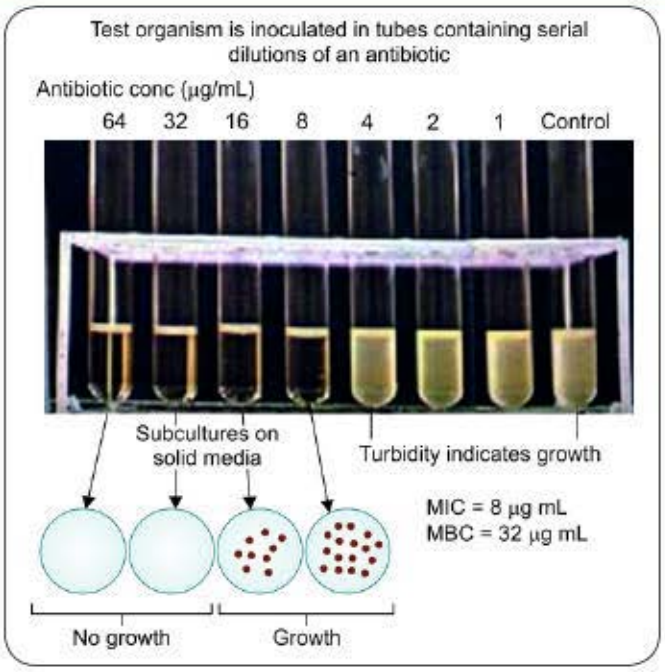
- MIC (minimum inhibitory concentration) is the lowest concentration of an antimicrobial agent that will inhibit the visible growth of a microorganism after overnight incubation.
- Depending upon whether the dilutions of the antimicrobial agent are made in agar or broth, there are two types of dilution tests.

Broth Dilution Method

- Serial dilutions of the antimicrobial agent in Mueller-Hinton broth are taken in tubes and each tube is inoculated with a fixed amount of suspension of the test organism. A control organism of known sensitivity should also be tested. Tubes are incubated at 37°C for 18 hours.
- The MIC is determined by noting the lowest concentration of the drug at which there is no visible growth, i.e. broth appears clear. (Fig. 7.5).
- The minimum bactericidal concentration (MBC) can be obtained by subculturing from each tube (showing no growth) onto a nutrient agar plate without any antimicrobial agent. The tube containing the lowest concentration of the drug that fails to show growth, on subculture, is the MBC of the drug for that test strain (Fig. 7.5).
- Broth dilution test can also be done using microtiter plates, such method is called as micro dilution method.

The MIC determination is useful in the following situations:

- For confirming the antimicrobial susceptibility test results obtained by disk diffusion tests.
- For testing antimicrobial sensitivities of—
  - Slow growing bacteria, such as tubercle bacilli.
  - Bacteria for which diffusion test is not standardized.
- When a very small degree of resistance has to be demonstrated.
- When the therapeutic dose of the drug has to be regulated accurately as in the treatment of bacterial endocarditis.



Test organism is inoculated in tubes containing serial dilutions of an antibiotic
Antibiotic conc (µg/mL)

Fig. 7.5: Broth dilution method

Agar Dilution Method

Here, the serial dilutions of the drug are prepared in molten agar and poured into Petri dishes. The test strain is spot inoculated. This method is more convenient than broth dilution and has the added advantage of:

- Several strains can to be tested at the same time by using the same plate
- It directly measures the MBC; there is no need of subculturing as it is done with broth dilution method.

Antibiotic Assays in Body Fluids

Antibiotic assay in body fluids is done to assess the toxic level and therapeutic level of the drug in blood and other body fluids. Both dilution and diffusion methods can be followed; by testing against a standard suspensions of bacteria with known MIC or zone of inhibition, respectively.

Fig. 7.6: Epsilometer or E-test

Epsilometer or E-test

This is a quantitative method of detecting MIC by using the principles of both dilution and diffusion of antibiotic into the medium.

- It uses an absorbent strip containing predefined gradient (serial dilution) of antibiotic concentration immobilized along its length.
- It is applied to a lawn inoculum of a bacterium. Following incubation of the test organism, an elliptical zone of inhibition is produced surrounding the strip.
- The antibiotic concentration at which the ellipse edge intersects the strip, is taken as MIC value (Fig. 7.6).

Automated Antimicrobial Susceptibility Tests

Several automated systems are available now, such as:

- VITEK 2 bacterial identification and antimicrobial sensitivity system (bioMerieux)
- Phoenix System (Becton Dickinson)
- Micro Scan Walk Away system

Most systems are computer assisted and have sophisticated softwares to analyze the growth rates and determine the antibiotic susceptibility report. They use commercially available panels that contain added growth factors to speed organism growth, thereby providing more rapid results compared with traditional methods.

Molecular Methods

PCR based assays are available targeting specific drug resistant genes; for example *mecA* gene for MRSA detection.

EXPECTED QUESTIONS

I. Write short notes on:

1. Mechanism of antibiotic resistance
2. Mutational and transferable drug resistance
3. Antimicrobial susceptibility testing method

II. Multiple Choice Questions (MCQs):

1. MRSA is mediated due to
a. Plasmid b. Chromosome
c. Transposons d. None

2. All of the following are diffusion methods for antimicrobial susceptibility except:
a. Kirby Bauer b. Stokes
c. Broth Dilution Method d. E test

3. Which of the following uses both diffusion and dilution methods for antimicrobial susceptibility:
a. Kirby Bauer b. Stokes
c. Broth Dilution Method d. E-test

Answers

1. b **2.** c **3.** d

CHAPTER 8

Microbial Pathogenicity

Chapter Preview

- Infection
- Sources and reservoir of infection
- Mode of transmission
- Mechanism of microbial pathogenicity

Depending upon the relationship of microbes with respect to humans, microorganisms may be of following types:

- **Saprophytes:** They are the free-living microbes that live on dead or decaying organic matter. They are usually found in soil and water and are generally unable to invade the living host.
- **Parasites:** They are the microbes that live on a living host, derive nutrition from the host and also cause harm to the host. They are of two types—microparasites (which include bacteria, viruses, fungi and protozoa) and macroparasites (which include helminths).
- **Commensals:** They are harmless microbes that harbor on a living host as normal flora of the host without causing any injury to the host.
- **Pathogens:** They are the microbes capable of causing disease. However, they represent only a very small proportion of the microbial world.
- **Opportunistic pathogens:** They are capable of causing disease only in immunocompromized people; when the usual defense mechanisms of humans are reduced or altered by accident, surgery, or by an underlying metabolic or an infectious disorder (e.g. AIDS).

INFECTION

Following the entry of the microorganism into the body, it may lead to either infection or colonization; both the terms need to be distinguished.

- **Infection:** It is a process in which a pathogenic organism enters, establishes itself, multiplies and invades the normal anatomical barrier of the host resulting in disease. When infection becomes apparent results in clinical manifestation and it is referred as 'infectious disease'.
- **Colonization:** Here, the pathogenic organism enters, multiplies but does not invade, and neither causes disease or nor elicits specific immune response.
  - Colonizers are different from normal flora. They have pathogenic potential and may invade and cause disease in another host or the same host later.
  - However commensals are limited to a particular anatomical site, e.g. intestine, respiratory and genital tract. When they enter through other routes, they may behave as pathogen.

For example, *Escherichia coli* is a normal flora in intestine, but it may result in either colonization or infection when enters through respiratory tract.

- **Infestation:** It is distinct from infection in that it applies specifically to parasites of macroscopic size, such as parasitic worms in intestine or arthropods (e.g. lice, itch mite, etc.) on the body surface.

Classification of Infections

Infections may be classified in various ways:

- **Primary infection:** It refers to the initial infection with a pathogenic microorganism in a host.
- **Reinfection:** It results following subsequent infection by the same microbe.
- **Secondary infection:** Here, a new pathogen sets up an infection in a host whose immunity is already lowered by a preexisting infection.
- **Focal infection** (or focal sepsis): It indicates a condition where, due to infection or sepsis at localized sites (such as in the appendix or tonsils), generalised effects are produced.
- **Superinfection:** It is defined as a second infection superimposed on an earlier one, by a different microbial agent of exogenous or endogenous origin, that is resistant to the treatment used against the first infection.
- **Cross-infections:** When in a patient already suffering from a disease a new infection sets up from another host or another external source, it is termed as cross-infection.

- **Nosocomial infections:** Cross-infections occurring in hospitals are called nosocomial infections. They are distinct from the patient's primary condition.
- **Iatrogenic (or physician induced) infection:** This refers to the infections induced by the professional activity of the physician or other health care workers resulting from preventive, diagnostic, treatment or other procedures.
- **Depending on the source of infection:**
  - Endogenous infections: The source of infection is within the body, either normal flora if breeches the anatomical barrier, or endogenous reactivation of a latent infection.
  - Exogenous infections: The source is outside the host's own body.
- **Based on the clinical manifestation produced:**
  - Asymptomatic or inapparent or subclinical infection: It is an infection that is active but does not produce noticeable symptoms.
  - Symptomatic or apparent infections: It may be classified into:
    - Acute infection: The symptoms last for a short term period, and
    - Chronic infection: The symptoms persist for a long period.
  - Latent infection: It refers to an infection that is inactive or dormant or in hidden form; but capable of reactivating later.
  - Atypical infection: Here, the usual manifestations of the disease are not present. Instead, atypical symptoms may be present.

Epidemiological Pattern of Infection

Four epidemiological terms are often used to describe infection—endemic, epidemic, pandemic and sporadic.

- **Endemic:** The infections that occur at a persistent, usually low level in a certain geographical area are called endemic.
- **Epidemic:** The infections that occur at a much higher rate than usual in a particular geographic area is known as epidemic.
- **Pandemic:** Infection that spreads rapidly over large areas of the world is known as pandemic.
- **Sporadic:** Infections occur at irregular intervals or only in a few plances; scattered or isolated.

SOURCES AND RESERVOIR OF INFECTION

The starting point for the occurrence of an infectious disease is known as a source or/and reservoir of infection. Source and reservoir are not always synonymous.

- **Source:** The source of infection refers to the person, animal, or object from which a microorganism is transmitted to the host.
- **Reservoir:** A reservoir is the natural habitat in which the organism lives, multiplies. Reservoir may be a person, animal, arthropod, plant, soil or substance (or combination of these) on which the organism is dependent for its survival; where it reproduces in, such a way that it can be transmitted to susceptible hosts.

The term source and reservoir may be same for many organisms but are not always synonymous. For example,

- In tetanus infection, the reservoir and source of the agent (*Clostridium tetani*) are same, i.e. the soil.
- In hook worm infection, the reservoir is man, but the source of infection is the soil contaminated with the larva of hook worm.
- In typhoid fever, the reservoir may be a case or carrier, but the source of infection is usually contaminated food and water.

Thus, the term 'source' refers to the immediate source of infection and may or may not be a part of reservoir.
The reservoir (and/or source) may be of three types.

Human Reservoir

By far the most important reservoir and/or source of infection for humans is man himself. Man is often described as his own enemy because most of the infectious diseases are contracted from human sources. The diseases that can be spread from one person to another are called **communicable diseases**. Human sources may be either cases or carriers.

- **Cases or patients:** They are the persons in a given population identified as having a particular disease. Cases may of various types depending upon the appearance of symptoms—subclinical, clinical and latent cases.
- **Carrier:** It refers to the persons/animals that harbor the infectious agent in the absence of any clinical symptoms and shed the organism from the body via contact, air or secretions.
  - It results due to inadequate treatment or immune response occurring in some diseases, which leads to incomplete elimination of the organism from the body.
  - Though, carriers are less infectious than cases, but are more dangerous as they often go undetected and continue to transmit the infection for a long period.

Types of Carriers

Carriers can be of various types:

- Incubatory carriers are those who shed the organism during the incubation period of disease. This usually occurs in the last few days of incubation period, e.g. measles, mumps, polio, diphtheria, pertussis, hepatitis B, influenza, etc.

Contd...

Contd...

- Healthy carriers refers to the subclinical cases who develop into carriers without suffering from overt disease, e.g. polio, cholera, salmonellosis, diphtheria, meningococcal meningitis, etc.
- Convalescent carrier is the one who has recovered from the disease and continues to harbor and shed the pathogen from his body.

Depending on the duration of carriage:

- Temporary carriers: They shed the organisms for less than six months. Incubatory, healthy and convalescent carriers are actually the types of temporary carriers.
- Chronic carriers: They shed the organisms for indefinite period, e.g. in hepatitis B, typhoid fever, malaria, gonorrhea, etc.

Depending on the source:

- Contact carrier is a person who acquires the pathogen from a patient.
- Paradoxical carrier refers to a carrier who acquires the pathogen from another carrier.

Animal Reservoir

The source of infection may sometime be animals and birds. The disease and the infections which are transmitted to man from vertebrates are called zoonoses. Common examples include:

- **From animals:** Rabies (from dog), leptospirosis (from rodents), influenza (from pigs), etc.
- **Birds** may be source of infection for various diseases like influenza, *Chlamydophila psittaci* infection (psittacosis), histoplasmosis, etc.

Amplifying host: It refers to the vertebrate reservoir in which the organism multiplies exponentially, e.g. pigs in Japanese B encephalitis.

Nonliving Things as Reservoir

Soil and inanimate matter can also act as reservoir/source of infection, for example soil may harbor the agents of tetanus, anthrax and some intestinal helminths.

MODE OF TRANSMISSION

Microorganisms may be transmitted from the reservoir or source to a susceptible host in different ways.

Contact

Infection may be transmitted by direct or indirect contact:

- **Direct contact** is via skin and mucosa of an infected person, e.g. through unclean hand, kissing, or sexual contact. Organisms transmitted by direct contact include agents of common cold, skin and eye infections and agents of sexually transmitted diseases (STD), such as HIV, *Neisseria gonorrhoeae*, *Chlamydia trachomatis* and *Treponema pallidum*, etc.
- **Indirect contact** is through the agency of fomites, which are inanimate objects, such as clothing, toys, etc. These may be contaminated by a pathogen and act as a vehicle for its transmission, e.g. face towels shared by various persons may lead to spread of trachoma.

Inhalation

Agents causing respiratory infections are acquired by inhalational route. These organisms are shed into the environment by patients in secretions from the nose or throat during sneezing, coughing or speaking in the form of droplets.

Air-borne Transmission

Droplet nuclei (<10 μm size) can remain suspended in air for long periods, and can act as source of infection.

- **Droplet (dust) transmission:** Larger droplets (>10 μm size) travel for a short distance, settle down on clothing and other objects and become a part of the dust. They can infect only those persons who come in contact with the source. Organisms transmitted through this route include respiratory viruses (e.g. influenza, parainfluenza virus, adenovirus, respiratory syncytial virus) and *Bordetella pertussis*.
- **Air-borne (droplet nuclei) transmission:** When the droplet is small (1–10 μm), it can travel a long distance; can infect any person it finds on its way. Primary contact with the source is not necessary. Organisms transmitted through this route include agents causing tuberculosis, measles and chickenpox.

Ingestion

Intestinal infections like cholera, dysentery, food poisoning and most of the parasitic infections are acquired by ingestion of food or drink contaminated by pathogens. Food-borne infections occur mostly through carriers engaged in handling or preparation of food and contaminating the food stuffs. The water supply may get contaminated with the feces of the patients or carriers. All these may transmit infection.

Inoculation

Pathogens, in some instances, may be inoculated directly into the skin or tissues of the host:

- Animal bite—for example, rabies virus is inoculated directly by the bite of a rabid animal.
- Inoculated directly into tissues. Spores of *Clostridium tetani* present in the soil, get deposited directly into the host tissues following severe wounds leading to tetanus.

Transmission of Blood-borne Infections

Blood-borne infections, such as hepatitis B, hepatitis C and HIV may be transmitted by:

- Needle prick and other sharp injuries

- Blood transfusion
- Intravenous drug abuse (contaminated needles)

Vector Borne (Mechanical or Biological)

Arthropod vectors, such as mosquitoes, flies, fleas, ticks, mite and lice are the vectors that transmit many diseases (Table 8.1). Vector may be of two types:

- **Mechanical vectors:** These carry the microorganisms (which do not multiply) and transmit them to the eatables.
- **Biological vectors:** The pathogen multiplies in the body of the vector, often undergoing part of a development cycle in it, such vectors are named biological vectors (e.g. female *Anopheles* mosquito in malaria; *Culex* mosquito in filariasis).

Extrinsic incubation period: After the entry of pathogen into the vector, the time required for the vector to become infective is called extrinsic incubation period.

Vertical Transmission

It refers to transmission of infection from mother to the fetus. It may be categorized into:

- **Transplacental transmission:** Infection occurs via the placental barrier; leads to abortion, miscarriage or stillbirth. If babies are born, they suffer from congenital malformations., such infections are known as teratogenic infections. Examples include TORCH infections:
  - *Toxoplasma*,
  - Others (*Treponema pallidum* and varicella-zoster virus)
  - Rubella virus
  - Cytomegalovirus
  - Herpes simplex virus
- **Transmission via the birth canal** without causing congenital malformation in the baby, Examples include: Group B *Streptococcus, N. gonorrhoeae, C.trachomatis, Listeria* and viruses (e.g. Hepatitis B, C and HIV).

TABLE 8.1: Arthropod vectors transmitting human infections

Vectors	Human infections transmitted
Mosquito	Malaria, filariasis, yellow fever, Japanese encephalitis, dengue fever,
Sandfly	Kala-azar, oriental sore, sandfly fever, Oroya fever
Hard tick	Tick typhus, Kyasanur forest disease (KFD), babesiosis, tularemia,
Soft tick	Q fever, endemic relapsing fever
Rat flea	Bubonic plague, endemic typhus, *Hymenolepis diminuta*
Trombiculid mite	Scrub typhus, rickettsial pox
Tsetse fly	Sleeping sickness
House fly	Typhoid fever, paratyphoid fever, cholera, gastroenteritis, trachoma
Louse	Epidemic typhus, epidemic relapsing fever, trench fever
Reduvild bug	Chagas disease
Cyclops	Guinea worm disease, fish tape worm

MECHANISM OF MICROBIAL PATHOGENICITY

Ability of a microbe to produce disease or tissue injury is often referred to as two closely related but not synonymous term 'pathogenicity' and 'virulence'.

- 'Pathogenicity' is generally employed to refer to the ability of a microbial species to produce disease.
- While the term 'virulence' is used more specifically to describe the relative degree of pathogenesis (tissue damage), which may vary between different strains of the same organism depending upon the expression of the virulence factors.
- Virulence is a relative term; it changes depending upon the expression of virulence factors which cause tissue damage. Different strains of same species may exhibit varying degrees of virulence. Some strains are highly virulent; while some strains are low and some are avirulent (vaccine strains).

The virulence of a strain may undergo spontaneous or induced variation.

- **Exaltation:** Enhancement of virulence is known as exaltation, which can be induced experimentally by serial passage into susceptible hosts.
- **Attenuation:** It refers to the reduction of virulence, which can be achieved by passage through unfavorable hosts, repeated cultures in artificial media, growth in high temperature or in the presence of weak antiseptics, desiccation or prolonged storage in culture.

Pathogenicity of viral, fungal and parasitic diseases are explained in the respective sections. Bacterial pathogenesis is described below.

Bacterial pathogenicity depends upon the sum total of several factors as described below.

Route of Transmission of Infection

Route of transmission of infection plays a crucial role in the pathogenicity of certain bacteria.

- Some bacteria, such as streptococci, can initiate infection whatever be the mode of entry.
- Others can survive and multiply only when introduced by the optimal routes. Cholera vibrios are infective orally but are unable to cause infection when introduced subcutaneously.
- This difference is probably related to the modes by which different bacteria are able to initiate tissue damage and establish themselves.

Infective Dose of the Organism

Infective dose of the organism is referred to as the minimum inoculum size that is capable of initiating an infection. Infective dose plays a major role in determining whether the disease is going to set in or not.

- **Low infective dose:** Certain organisms require a relatively small inoculum to initiate infection.
  - *Shigella*: Very low (as low as 10 bacilli)
  - *Cryptosporidium parvum:* Very low (10–30 oocysts)
  - *Escherichia coli* O157: H7 (<10 bacilli)
  - *Entamoeba coli and Giardia*: few cysts
  - *Campylobacter jejuni* (500 bacilli)
- **Large infective dose:** In contrast, organisms with high infective dose can initiate the infection only when the inoculum size exceeds a particular critical size.
  - *Escherichia coli* (10^6–10^8 bacilli)
  - *Salmonella* (10^2–10^5 bacilli)
  - *Vibrio cholerae* (10^6–10^8 bacilli)

Infective dose varies depending upon the factors, such as:

- Virulence of the organism: Higher the virulence, lower is the infective dose.
- Host's age and overall immune status
- Ability of the organism resisting the gastric acidity: *Shigella* has an ability to survive in gastric acidity, even a low infective dose can initiate the infection. In contrast *Vibrio* is extremely acid labile, hence requires a heavy inoculum to bypass the gastric barrier.

Adhesion

Adhesion of the bacteria to body surfaces is the initial event in the pathogenesis of the disease. It is mediated by specialized molecules called adhesins which bind to specific host cell receptors. Adherence prevents the bacteria from being flushed away in secretions and also facilitates bacterial invasion into the host cells.

- **Fimbriae or pili:** They are the most important adhesins present in some bacteria. They directly bind to the sugar residues (glycolipids or glycoproteins) on host cells.
- **Non pilus adhesins:** Apart from pili, there are other adhesins found in certain bacteria, such as M protein (*Streptococcus pyogenes*), lipoteichoic acid (gram-positive cocci), cell surface lectin (*Chlamydia*), etc.
- **Biofilm formation:** It is another mechanism by which certain bacteria mediate strong adherence to certain structures, such as catheters, prosthetic implants, and heart valves. Biofilm is a group of bacterial cells which stick to each other on a surface and are embedded within layer (called slime layer) of a self-produced matrix of extracellular polymeric substance called glycocalyx.

Invasion

Invasion refers to entry of bacteria into host cells, leading to spread within the host tissues.

- Highly invasive pathogens produce spreading or generalized lesions (e.g. streptococcal infections), while less invasive pathogens cause localized lesions (e.g. staphylococcal abscess).
- Some pathogens though capable of causing fatal diseases, lack invasiveness but remain confined to the site of entry and produce disease by elaborating a potent toxin, e.g. *Clostridium tetani*.

Important virulence factors that help in invasion include:

- Virulence marker antigen or invasion plasmid antigens in *Shigella*.
- Enzymes: Invasion of bacteria is enhanced by many enzymes such as: hyaluronidase, collagenase, streptokinase, IgA proteases.

- **Antiphagocytic Factors:** Bacteria are rapidly killed once they are ingested by phagocytes, such as polymorphonuclear cells (neutrophils) or macrophages. Some pathogens develop strategies to evade phagocytosis by several antiphagocytic factors, the most important ones being—
- **Capsule:** It prevents phagocytosis of bacteria by preventing the phagocytes from adhering to the bacteria. Capsules are produced by—
  - *Neisseria meningitidis*
  - *Streptococcus pneumoniae*
  - *Haemophilus influenzae*
  - *Klebsiella pneumoniae*
  - *Cryptococcus neoformans* (fungus)
- **Cell wall proteins** may help in invasion, such as—
  - Protein A of *Staphylococcus aureus* binds to IgG and prevents the activation of complement.
  - M protein of *Streptococcus pyogenes*
- **Cytotoxins:** Certain bacteria produce cytotoxins that interfere with chemotaxis or killing of phagocytes. For example, *S. aureus* produces hemolysins and leukocidins that lyse and damage RBCs and WBCs.

Intracellular Survival

Some organisms survive in intracellular environment. They are grouped into obligate and facultative intracellular organisms (Table 8.2). Once engulfed, they develop strategies that inhibit various steps of phagocytosis (Table 8.3).

Toxins

Endotoxins

Endotoxins are the lipid A portion of lipopolysaccharide (LPS). They are present as an integral part of the cell wall of gram-negative bacteria. They are released from the bacterial surface by natural lysis of the bacteria and are responsible for various biological effects in the host (Fig. 8.1).

- **Macrophage activation:** Endotoxin binds to specific receptors on macrophages and stimulates the release of

TABLE 8.2: Intracellular organisms

Facultative intracellular organism	Obligate intracellular organism
Bacteria	
Salmonella Typhi, *Brucella* *Legionella, Listeria, Nocardia,* *Neisseria meningitidis, Yersinia* *Mycobacterium tuberculosis*	*Mycobacterium leprae* *Rickettsia* *Chlamydia* *Coxiella burnetii*
Viruses	
	All viruses
Fungi	
Histoplasma capsulatum *Cryptococcus neoformans*	*Pneumocystis jirovecii*
Parasites	
	Toxoplasma, Cryptosporidium, *Plasmodium, Leishmania,* *Babesia, Trypanosoma*

TABLE 8.3: Mechanisms used by organisms for intracellular survival

Mechanism of intracellular survival	Organism
Inhibition of phagolysosome fusion	*Legionella* species, *Mycobacterium tuberculosis,* *Chlamydia* species
Resistance to lysosomal enzymes	*Salmonella* Typhimurium, *Coxiella* species, *Mycobacterium leprae,* *Leishmania* species
Adaptation to cytoplasmic replication	*Listeria, Rickettsia* *Francisella tularensis*

acute-phase cytokines, such as interleukin (IL)-1, tumor necrosis factor-α, IL- 6, nitric oxide and prostaglandins which cause fever and inflammation and activation of immune system (T cells and B cells).

- **Complement activation:** High concentrations of endotoxin can activate the alternative pathway of complement → release C3a and C5a → promote inflammatory cells chemotaxis, high grade fever, hypotension, shock produced by vasodilatation and capillary leakage.
- **Endothelial activation:** Leads to ↑ vascular permeability.
- **Coagulation pathways activation:** It activates Hageman factor and other coagulation factors, leads to thrombosis, and disseminated intravascular coagulation (DIC).
- **Platelet activation:** Leads to release of mediators that cause ↑ vascular permeability, thrombosis, and DIC.
- **Mast cell activation:** Leads to release of mediators (e.g. histamine) that causes muscle contraction and ↑ vascular permeability.
- **In gram-negative septicemia:** Endotoxins are released in large quantity, causing high fever, petechiae (skin lesions resulting from the capillary leakage) and DIC which may result in shock and possibly death.

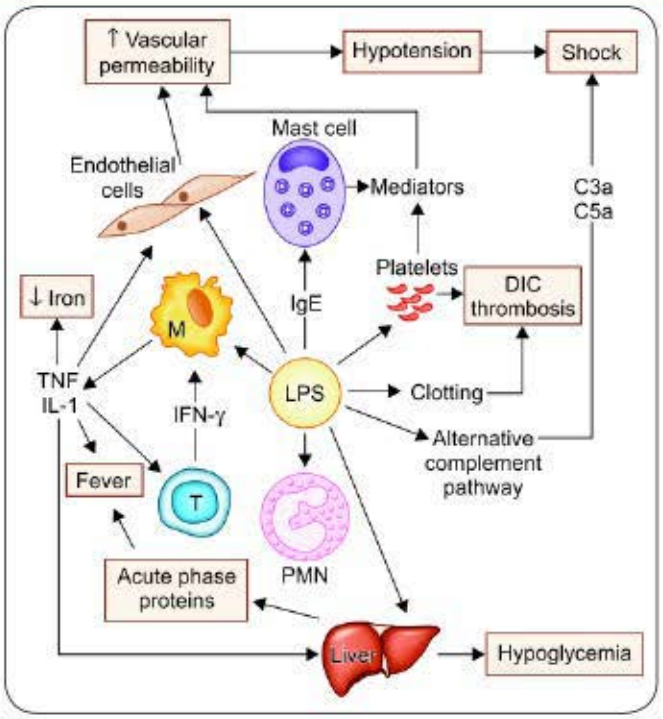

Fig. 8.1: Effects of bacterial endotoxins (cell wall lipopolysaccharide)

Abbreviations: DIC, disseminated intravascular coagulation; LPS, lipopolysaccharide; IL-1 interleukin-1; IFN-γ, interferon gamma; PMN, polymorphonuclear leukocyte; IgE, immunoglobulin E

Exotoxins

They are heat labile proteins; secreted by certain species of both gram-positive and gram-negative bacteria and diffuse readily into the surrounding medium.

- **High potency:** Exotoxins are highly potent even in minute amounts. Botulinum toxin is the most potent, it has been estimated that 39.2 g of botulinum toxin would be sufficient to eradicate the entire humankind.
- **Used for vaccine:** Exotoxins can be converted into toxoids by treatment with formaldehyde. Toxoids lack toxicity but retain antigenicity and thus induce protective immunity when used as vaccines.
- **Specific action:** They are highly specific for a particular tissue, e.g. tetanus toxin for CNS. They have specific pharmacological activities (Table 8.4).

Exotoxins differ from endotoxins in several ways (Table 8.5).

Pathogenicity Islands

Pathogenicity islands (PAIs) are large genomic islands located in the chromosomal regions of some bacteria containing sets of genes encoding numerous virulence factors, such as adhesins, secretion systems, toxins, invasins, iron uptake system, etc.

- Genes encoded in a pathogenicity island are expressed in a coordinated way to initiate the virulence process.

TABLE 8.4: Bacterial exotoxins and their mechanism of action

Organisms	Toxins (Exotoxins)	Mechanism
Staphylococcus aureus	Enterotoxin, Toxic shock syndrome toxin	Act as super antigen; stimulate T cell nonspecifically, to release large amounts of cytokines
Streptococcus pyogenes	Streptococcal pyrogenic exotoxin	
Corynebacterium diphtheriae	Diphtheria toxin (DT)	Inhibits protein synthesis (by inhibiting elongation factor-2)
Bacillus anthracis	Anthrax toxin	↑cAMP in target cell, edema
Clostridium perfringens	α toxin and other major and minor toxins	Lecithinase and phospholipase activity → causes myonecrosis
Clostridium tetani	Tetanus toxin (tetanospasmin)	Decrease in neurotransmitter (GABA and glycine) release from the inhibitory neurons → spastic paralysis
Clostridium botulinum	Botulinum toxin BT)	Decrease in neurotransmitter (acetyl choline) release from neurons → spastic paralysis
Escherichia coli (diarrheagenic)	Heat labile toxin (LT)	Activation of adenylate cyclase, → cAMP in target cell → secretory diarrhea
	Heat stable toxin (ST)	↑cGMP in target cell → secretory diarrhea
	Verocytotoxin	Inhibit protein synthesis (by inhibiting ribosome)
Shigella dysenteriae type-1	Shiga toxin	
Vibrio cholerae	Cholera toxin (CT)	Activation of adenylate cyclas → cAMP in target cell → secretory diarrhea
Pseudomonas	Exotoxin-A	Inhibit protein synthesis (by inhibiting elongation factor-2)

TABLE 8.5: Differences between bacterial endotoxins and exotoxins

Feature	Endotoxins	Exotoxins
Nature	Lipopolysaccharides	Proteins
Source	Part of cell wall of gram-negative bacteria	Secreted both by gram-positive and negative bacteria; diffuse into surrounding medium
Released by	Cell lysis Not by secretion	Actively secreted by the bacteria
Heat stability	Highly stable	Heat labile destroyed at 60°C
Mode of action	↑IL-1 and TNF	Mostly enzyme like action
Effect	Nonspecific (fever, shock, etc.)	Specific action on particular tissues
Tissue affinity	No	Specific affinity for tissues
Fatal dose	Only large doses are fatal	More potent, even smaller doses–fatal
Antigenicity	Poorly antigenic	Highly antigenic
Neutralization by antibodies	Ineffective	Neutralized by specific antibodies
Used for vaccine	No effective vaccine is available using endotoxin	Toxoid forms are used as vaccine, e.g. tetanus toxoid

- These genes may be turned on by a single stimulus (e.g. the temperature of the gut) and can be transferred as a unit by horizontal gene transfer mechanisms to different sites within a chromosome or to other bacteria.
- Pathogenicity islands have been detected in some bacteria, such as *Shigella*, *Salmonella*, *Vibrio cholerae*, *Yersinia pestis*, *Staphylococcus aureus*, uropathogenic *E. coli*, *Helicobacter*.

Bacterial Secretory System

Secretion in bacteria refers to the translocation of effector molecules, such as proteins, enzymes or toxins (such as cholera toxin) across the cell membrane from cytoplasm to its exterior. Secretion is a very important mechanism for bacterial survival and pathogenesis. There are at least six specialized secretion systems described especially in gram-negative bacteria (type I to type VI).

EXPECTED QUESTIONS

I. Write short notes on:

a. Reservoirs of infection
b. Carriers
c. Various modes of transmission of infection
d. Mechanisms of microbial pathogenicity
e. Differences between endotoxins and exotoxins

II. Multiple Choice Questions (MCQs):

1. Chemical nature of endotoxin is:
a. Lipopolysaccharide b. Protein
c. Carbohydrate d. None

2. All of the following are exotoxins except:
a. Botulinum toxin b. Anthrax toxin
c. Diphtheria toxin
d. lipid A portion of lipopolysaccharide

3. All of the following are vector borne diseases except?
a. Malaria b. Fialriasis
c. Rubella d. Chagas disease

Answers

1. a **2.** d **3.** c **4.** d

CHAPTER 9

Immunity (Innate and Acquired)

Chapter Preview

- Innate immunity
- Acquired or adaptive immunity
  - Active immunity
    - Primary immune response
    - Secondary immune response
  - Passive immunity
- Bridges between innate and acquired immunity
- Other types of immunity
  - Local (or mucosal) immunity
  - Herd immunity
  - Adoptive immunity

The term "immunity" (Latin word "*immunitas*", means freedom from disease) is defined as the resistance offered by the host against microorganism(s) or any foreign substance(s). Immunity can be broadly classified into two types:

1. Innate immunity—present right from the birth
2. Acquired/adaptive immunity—acquired during the course of the life

INNATE IMMUNITY

Innate immunity is the inborn resistance against infections that an individual possesses right from the birth, due to his genetic or constitutional makeup.

Innate immunity has certain unique properties by which it can be differentiated from acquired immunity (Table 9.1).

- **Acts in minutes:** Innate immunity is the **first line of host defense** against infections; occurs immediately after the microbial entry.
- **Microbial exposure is not required:** Innate immunity is independent of prior exposure to the microbes; present even before the first entry of the microorganism.
- **Diversity is limited:** Innate immunity is active only against a limited repertoire of antigens; in contrast to acquired immunity which is more varied and involves specialized immune responses.
- **Non-specific:** Cells of innate immunity are non-specific in their action; can be directed against any microbial antigen(s).
- **No memory:** Innate immunity does not have a memory component. Response to a repeat infection is identical to the primary response.

Innate immunity may be confined to a particular species, race or individual.

- **Species immunity** is the innate immunity towards a microbe exhibited by all members of a given species. For example, frogs are resistant to *Bacillus anthracis*; while toads are susceptible.
- **Racial immunity:** Sometimes, innate immunity is confined to a particular race; may be absent in other communities. For example, Negroes of America are more susceptible to tuberculosis than the Whites.
- **Individual immunity** refers to the antimicrobial defense mechanisms that are confined to a particular individual; may not be exhibited by others.

Several factors determine the degree of innate immunity exhibited by the host, such as:

- **Age:** Certain infections are common in a particular age. For example, congenital infections like rubella is common in fetal life, chickenpox and measles occur in children, whereas urinary tract infection is common in adults.
- **Hormone:** Certain hormonal disorders (e.g. diabetes mellitus) or patients on hormone therapy (e.g. corticosteroids) are at increased risk of developing various infections.
- **Nutrition:** Malnutrition suppresses the host immunity, thereby predisposes to various infections.

TABLE 9.1: Differences between innate and acquired immunity

Innate immunity	Acquired / Adaptive immunity
Resistance to infection that an individual possesses from birth	Resistance to infection that an individual acquires during his lifetime
Immune response occurs in minutes	Immune response occurs in days
Prior exposure to the antigen is not required	Develops following the antigenic exposure
Diversity is limited, acts through a restricted set of reactions	More varied and specialized responses
Immunological memory responses are absent	Immunological memory responses are present
Microbial antigen: Innate immunity develops against antigens that are shared by many microbes (called microbes-associated molecular patterns)	Microbial antigen: Acquired immunity develops against antigens that are specific for each microbes.
Host cell receptors of innate immunity (called pattern recognition receptors) are non-specific, e.g. Toll-like receptor	Host cell receptors are specific, e.g. T cell receptors and B cell immunoglobulin receptors
Components of innate immunity ▪ Anatomical barriers such as skin and mucosa ▪ Physiological barriers (e.g. body temperature) ▪ Phagocytes (neutrophils, macrophages and monocytes) ▪ Natural killer (NK) cells ▪ Other classes of lymphocytes— • γδT cells, NK-T cells • B-1 cells and marginal-zone B cells ▪ Mast cells and dendritic cells ▪ Complement pathways—alternate and mannose binding pathways ▪ Fever and inflammatory responses ▪ Normal resident flora ▪ Cytokines: TNF-α, interleukins (IL-1, IL-6, IL-8, IL-12, IL-16, IL-18), IFN-α, β and TGF- β ▪ Acute phase reactant proteins (APRs)	**Components of acquired immunity** T cell B cell Classical complement pathway Antigen presenting cells Cytokines (IL-2, IL-4, IL-5, IFN-γ) **Types of acquired immunity** It can be classified in two ways: ▪ Active and passive immunity ▪ Artificial and natural immunity

Abbreviations: TNF, tumor necrosis factor; TGF-β, transforming growth factor. β; IFN, interferon

MECHANISMS OF INNATE IMMUNITY

Receptor Interaction

Following the exposure to microorganisms, several mediators of innate immunity are recruited to the site of infection (Table 9.1). The first step that takes place is **attachment,** which involves binding of the surface molecules of microorganisms to the receptors of cells of innate immunity.

Microbial Surface Molecules

They are the repeating patterns of conserved molecules which are common to most microbial surfaces; called **Microbes-associated molecular patterns (MAMPs).** Examples of MAMPs include peptidoglycan, lipopolysaccharides (LPS), teichoic acid and lipoproteins present on bacterial surface.

Pattern Recognition Receptors (PRRs)

These are the molecules present on the surface of host cells (e.g. phagocytes) that recognize MAMPs. They are generally conserved regions, encoded by germ line genes. **Toll-like receptors (TLRs)** are classical examples of pattern recognition receptors (see box below).

- Signals generated following binding of TLRs to MAMPs activate transcription factors that stimulate expression of genes encoding cytokines and enzymes, which are involved in several antimicrobial activities of cells of innate immunity.
- The most important transcription factors activated by TLR signals are:
  - **Nuclear factor κβ (NF-κβ),** which promotes production of various cytokines and
  - **Interferon regulatory factors (IRFs),** which stimulate expression of the antiviral interferons α and β.

Toll-like Receptors

They are so named because they are similar to Toll receptors present in the fruit fly (*Drosophila*), where it is the main receptor for induction of innate immunity.

There are **13 types** of Toll-like receptors (TLR 1 to 13) recognized so far which bind to particular **MAMP** molecules on microbial surfaces. Important ones are:

- TLR-2 binds to bacterial peptidoglycan
- TLR-3 binds to dsRNA of viruses
- TLR-4 binds to LPS of gram-negative bacteria
- TLR-5 binds to flagella of bacteria
- TLR-7 and 8 bind to ssRNA of viruses
- TLR-9 binds to bacterial DNA

Components of Innate Immunity

There are several mediators of innate immunity. They exert antimicrobial activities by various mechanisms as described below. More so, many mediators are not purely part of innate immunity; they often act as bridge between innate and acquired immunity (e.g. complements and macrophages).

Anatomical and Physiological Barriers

- Anatomical barriers such as skin and mucosal surfaces have a spectrum of antimicrobial activities (Table 9.2).
- Physiological barriers that contribute to the innate immunity are the body temperature, pH and various soluble secretory products of mucosa (Table 9.2).

TABLE 9.2: Role of barriers in innate immunity

Anatomical barrier	Function
Skin barrier	
	▪ Mechanically prevents entry of microbes ▪ Produces sebum containing antimicrobial peptides and fatty acids ▪ Killing of microbes by intraepithelial lymphocytes
Mucosal barrier	
Mucous membrane	Prevents entry of microbes mechanically and by producing **mucous** which entraps microbes
Cilia	Cilia present in the lower respiratory tract propel the microbes outside
Normal flora	Intestinal and respiratory mucosa are lined by normal flora
Physiological barrier	**Function**
Temperature	Normal body temperature inhibits the growth of some microbes
Low pH	Gastric acidity inhibits most of the microbes
Secretory products of mucosa	
Saliva	Enzymes in saliva damage the cell wall and cell membrane of bacteria
Tears	Contains lysozyme that destroys the peptidoglycan layer in bacterial cell wall
Gastric juice	HCl kills microbes by its low pH
Trypsin	Hydrolyses bacterial protein
Bile salts	Interfere with bacterial cell membrane
Fatty acids	Denature the bacterial proteins
Spermine	Present in semen, inhibits growth of gram-positive bacteria
Lactoferrin	Binds to iron, thus interferes with acquisition of iron by bacteria

Phagocytes

Phagocytes such as **neutrophils, macrophages** including **monocytes** are the main component of innate immunity. They are rapidly recruited to the infection site. Phagocytosis involves three sequential steps—(1) engulfment of microbes and subsequent hosting in phagosome, (2) fusion of lysosome with phagosome to form phagolysosome and (3) microbial killing (described in Chapter 14)

Natural Killer (NK) Cells

They are a class of lymphocytes that kill virus infected cells and tumor cells. NK cell mediated mechanism of killing microbes is desribed in Chapter 15.

Other Rare Classes of Lymphocytes

T and B lymphocytes are the chief mediators of acquired immunity. However, there are several rare types of lymphocytes that share the features of both acquired and innate immunity (Described in detail in Chapter 14), e.g.

- γδ **T cells** (also called intraepithelial lymphocytes): They are present in epithelial lining of skin and mucosa.
- **NK-T cells:** They are present in epithelium and lymphoid organs.
- **B-1 cells:** They are found mostly in the peritoneal cavity and mucosal tissues.
- **Marginal-zone B cells:** They are present at the edges of lymphoid follicles of spleen.

Mast Cells

They are present lining the respiratory and other mucosa.

- They are activated by microbial products binding to toll-like receptors or by IgE antibody dependent mechanism, following which;
- They release abundant cytoplasmic granules rich in histamine, prostaglandins and cytokines that initiate inflammation and proteolytic enzymes that results in killing of bacteria.

Dendritic Cells

They respond to microbes by producing numerous cytokines that initiate inflammation. They also serve as vehicle in transporting the antigen(s) from the skin and mucosal sites to lymph nodes where they present the antigen(s) to T cells. Hence, dendritic cells serve as a bridge between innate and acquired immunity.

Complement Pathways

Alternate and mannose binding pathways are the chief mediators of innate immunity.

- Alternate complement pathway is activated in response to bacterial endotoxin whereas the mannose binding pathway is stimulated by mannose carbohydrate residues on bacterial surface.

- Following activation, the complements mediate various biological functions such as (refer Chapter 13)
  - Lysis of the target microbes (by forming pores on the microbial surfaces)
  - Stimulate inflammation (by secreting inflammatory mediators)
  - Stimulate acquired immunity: Complements are another bridge between innate and acquired immunity.

Inflammatory Response

Inflammation is defined as the biological response of vascular tissues to harmful stimuli, such as microorganisms or other foreign substances. The major events that take place during an inflammatory response following a microbial entry are as follows (Fig. 9.1):

- **Vasodilation** due to release of vasoactive substances from the damaged tissues
- **Leakage** of plasma proteins through blood vessels
- **Recruitment** of phagocytes (e.g. neutrophils) to the site of inflammation—phagocytes undergo the following steps—(1) margination (adherence to the endothelium), (2) rolling on endothelium, (3) extravasation (moves out of the blood vessels), (4) chemotactic migration to the inflammation site
- **Engulfment** of microbes and dead material by the phagocytes
- **Destruction** of the microbes

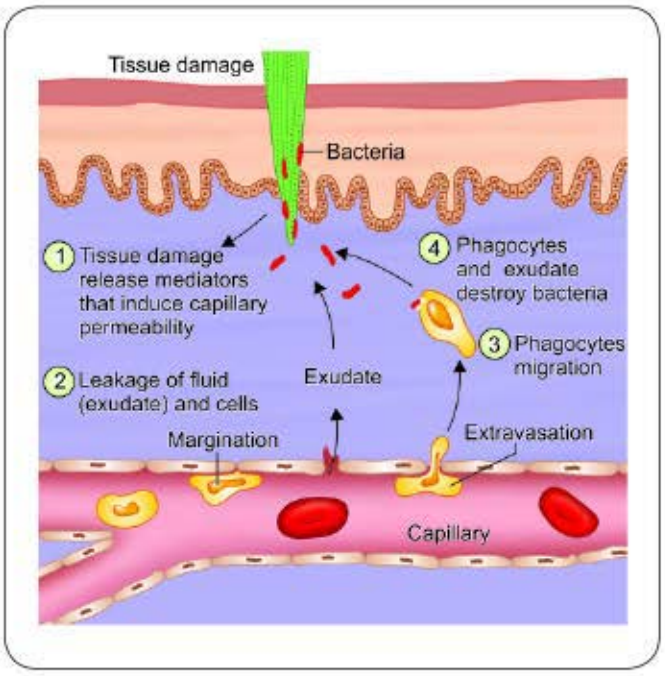

Fig. 9.1: Major events in an inflammatory response

Inflammation is not always protective in nature, sometime it may produce injurious consequences to host tissues called **hypersensitivity reactions**.

Normal Resident Flora

Normal resident flora lining intestinal, respiratory and genital tract exert several antimicrobial activities. (detail is described in chapter 53)

- They compete with the pathogens for nutrition .
- They produce antibacterial substances.

Cytokines

In response to the microbial antigens, dendritic cells, macrophages, and other cells secrete several cytokines that mediate many of the cellular reactions of innate immunity such as:

- Tumor necrosis factor-α (TNF-α),
- Interleukin-1 (IL-1), IL-6, IL-8, IL-12 and IL-16
- Interferons (IFN-α, β) and
- Transforming growth factor (TGF-β)

Acute Phase Reactant Proteins (APRs)

They are the proteins synthesized by liver at steady concentration, but their synthesis either increases or decreases exponentially during acute inflammatory conditions. Though liver is the primary site, APRs can also be synthesized by various other cells such as endothelial cells, fibroblasts, monocytes and adipocytes.

- **Positive APRs:** They are the proteins whose levels increase during acute inflammation. Examples include:
  - Serum amyloid A
  - C- Reactive protein
  - Complement proteins—complement factors (C1-C9), factor B,D, and properdin
  - Coagulation protein, e.g. fibrinogen, von Willebrand factor
  - Proteinase inhibitors, e.g. α1 antitrypsin
  - α1 acid glycoprotein
  - Mannose binding protein
  - Haptoglobin
  - Metal binding proteins, e.g. ceruloplasmin
- **Negative APRs:** They are the proteins whose levels are decreased during acute inflammation; thus creating a negative feedback that stimulates the liver to produce positive APRs. Examples of negative APRs include albumin, transferrin and antithrombin.
- **Role of APRs:** They have a wide range of activities that contribute to the host defense.
  - APRs have various antimicrobial and anti-inflammatory activities (e.g. complement factors).
  - Metal binding proteins can chelate various metals such as iron, copper, etc making them unavailable for the bacteria.

C- Reacting Protein (CRP)

C-reacting protein is an example of APR that rise in acute inflammatory conditions including bacterial infections. It belongs to beta globulin family.

- CRP is so named because it precipitates with C-carbohydrate (polysaccharide) antigen of pneumococcus. However, it is not an antibody against the C-carbohydrate antigen of pneumococcus; it is non-specific, can be raised in any inflammatory conditions.
- It is one of the most common markers of acute inflammation, used in most diagnostic laboratories.

CRP Level

The normal level of CRP is less than 0.2mg/dL. However, it increases by several folds in acute inflammatory conditions.

- **Insignificant increase** of CRP (<1 mg/dL): It occurs in conditions such as heavy exercise, common cold, and pregnancy.
- **Moderate increase** (1–10 mg/dL): It occurs in conditions such as bronchitis, cystitis, malignancies, pancreatitis, myocardial infarction.
- **Marked increase** of CRP (>10 mg/dL): It occurs in conditions such as acute bacterial infections, major trauma and systemic vasculitis.

CRP Can be Detected by

- Precipitation method using C-carbohydrate antigen (obsolete, not in use now)
- Latex (passive) agglutination test using latex particles coated with anti-CRP antibodies.
  - It is the most widely used method employed worldwide.
  - Detection limit of CRP by latex agglutination test is 0.6 mg/dL

Highly Sensitive CRP (hs-CRP) Test

Minute quantities of CRP can be detected by various methods (e.g. nephelometry, enzyme immunoassays). This is useful in assessing the risk to cardiovascular diseases.

ACQUIRED OR ADAPTIVE IMMUNITY

Acquired immunity is defined as the resistance against the infecting foreign substance that an individual acquires or adapts during the course of his life.

Acquired immunity has unique properties by which it can be differentiated from innate immunity (Table 9.1).

- **Mediators: T cells and B cells** are the chief mediators of acquired immunity. Other mediators include:
  - Classical complement pathway
  - Antigen presenting cells
  - Cytokines (IL-2, IL-4, IL-5)
- **Response occurs in days:** Acquired immunity involves activation of T and B cells against the microbial antigens; which takes several days to weeks to develop, following the microbial entry.
- **Requires prior microbial exposure:** Acquired immunity develops only after the exposure to the microbes. It is not present prior to the first contact with the microbes.
- **Specific:** Acquired immunity is highly specific; directed against specific antigens that are unique to the microbes.
- **Memory present:** Acquired immunity does have a memory component. A proportion of T and B cells become memory cells following primary contact of the microbe, which play an important role when the microbe is encountered subsequently.
- **Diversity is wide:** Acquired immunity though takes time to develop, is active against a wide range of repertoire of antigens.
- **Host cell receptors** of acquired immunity are specific for particular microbial antigen.
  - Examples include T cell receptors and B cell immunoglobulin receptors.
  - They are encoded by genes produced by somatic recombination of gene segments.

Types of acquired immunity: Acquired immunity can be classified in two ways:

- Active and passive immunity
- Artificial and natural immunity

ACTIVE IMMUNITY

Active immunity is the resistance developed by an individual toward an antigenic stimulus.

- Here, the host's immune system is actively involved in response to the antigenic stimulus; leading to the production of immunologically active T cells, B cells and production of specific antibodies.
- Active immunity may be induced naturally or artificially.
  - **Natural active immunity** occurs following an exposure to a microbial infection (e.g. measles virus infection)
  - **Artificial active immunity** develops following an exposure to an immunogen by vaccination (e.g. measles vaccine). Vaccines are discussed in Chapter 20.
- As host's immune apparatus is actively involved, active immunity often fails to develop when the host is immunocompromized.
- **Long-lasting:** Active immunity usually lasts for longer periods, but the duration varies depending on the type of pathogen.
  - It may last life long, e.g. following certain viral infections such as chickenpox, measles, smallpox, mumps and rubella.
  - It may last short, e.g. following influenza virus infection.
  - It may last for as long as the microbe is present. Once the disease is cured, the patient becomes susceptible to the microbe again. This is called

premunition or concomitant immunity. It is seen following some microbial infections like spirochetes and *Plasmodium*.

- Active immunity may not be protective at all, e.g. for *Haemophilus ducreyi*, the patient may develop genital lesions following reinfection even while the original infection is active.

Types of immune response in active immunity vary depending on the microbial exposure that occurs for the first time (called primary immune response) and subsequent time (called secondary immune response).

Primary Immune Response

When the antigenic exposure occurs for the first time, the following events take place:

- **Latent or lag period:** Active immunity develops only after a latent period following the antigenic exposure, which corresponds to the time required for the host's immune apparatus to become active.
- **Effector cells:** Majority of activated T and B cells against the antigenic stimulus become effector T and B cells
  - Effector T cells such as helper T cells and cytotoxic T cells
  - Effector B cells include plasma cells
- **Memory cells:** A minor proportion of stimulated T and B cells become memory cells, which are the key cells for secondary immune response.
- **Antibody surge:** Effector B cells produce antibodies (mainly IgM type). Antibodies appear in the serum in slow and sluggish manner; reach peak, maintain the level for a while and then fall down. Finally, a low titer of baseline antibodies may be maintained in the serum (Fig. 9.2).

Secondary Immune Response

When the same antigenic exposure occurs subsequently, the events which take place are as follows (Fig. 9.2).

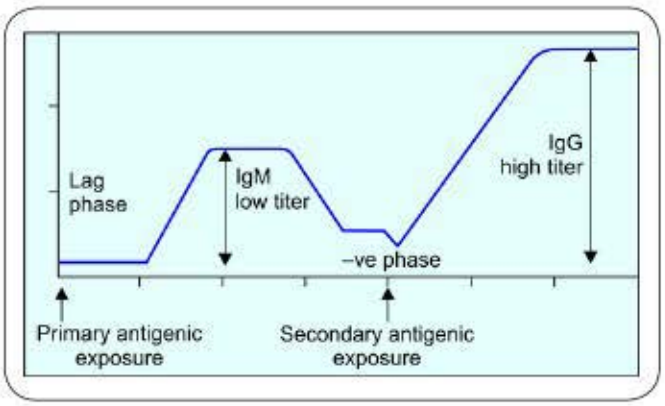

Fig. 9.2: Primary and secondary immune responses

TABLE 9.3: Differences between primary and secondary immune response

Primary immune response	Secondary immune response
Immune response against primary antigenic challenge	Immune response against subsequent antigenic challenge
Slow, sluggish (appear late) and short lived	Prompt, powerful and prolonged (long lasting)
Lag period is longer (4–7 days)	Lag period is absent or short (1–3 days)
No negative phase	Negative phase may occur
▪ Antibody produced in low titer and is of IgM type. ▪ Antibodies are more specific but less avid	Antibody produced in high titer and is of IgG type Antibodies are less specific but more avid
Antibody producing cells—Naive B cells	Antibody producing cells—Memory B cells
Both T dependent and T independent antigens are processed	Only T dependent antigens are processed

- **Latent period** is either absent or of short duration. This is because memory cells become active soon after the antigenic exposure.
- **Negative phase:** At the onset of secondary immune response, there may be a negative phase during which the antibody level may become lower than it was before the antigenic stimulus. This is because the exposed antigen combines with the pre-existing antibody and thus the antibody level in serum falls down.
- **Antibody surge:** Secondary antibody response is prompt, powerful, long-lasting and mainly of IgG type. Hence it is said that, the booster doses of vaccines are more effective than the first dose.

The differences between primary and secondary immune response are tabulated in Table 9.3.

PASSIVE IMMUNITY

Passive immunity is defined as the resistance that is transferred passively to a host in a "readymade" form without active participation of the host's immune system.

- Passive immunity can also be induced naturally or artificially.
  - **Natural passive immunity** involves the IgG antibody transfer from mother to fetus across the placenta.
  - **Artificial passive immunity** develops following readymade transfer of commercially prepared immunoglobulin (e.g, Rabies immunoglobulin).
- Passive immunity plays a very important role in:
  - Immunodeficient individuals (as host's immune apparatus is not effective) and;
  - Post exposure prophylaxis; when an immediate effect is warranted.

TABLE 9.4: Differences between active and passive immunity

Active immunity	Passive immunity
Produced actively by host immune system	Immunoglobulins received passively
Induced by: ▪ Infection (natural) ▪ Vaccination (artificial)	Acquired by: ▪ Mother to fetus IgG transfer (natural) ▪ Readymade antibody transfer (artificial)
Long lasting	Lasts for short time
Lag period present	No Lag period
Memory present	No memory
Booster doses—useful	Subsequent doses—less effective
Negative phase may occur	No negative phase
Not useful in immunodeficiency individuals	Useful in immunodeficient individuals

- Passive immunity **develops faster**; there is no lag phase or negative phase.
- There is no **immunological memory** as the memory cells are not involved.
- **Booster doses are not effective:**
  - As memory component is absent, the effect produced following subsequent immunoglobulin administration is same as the effect produced after the primary dose.
  - Some time, the booster doses of an immunoglobulin may be less effective because of its immunological clearance, which is mediated by the antibodies produced against the first dose of immunoglobulin.

The differences between active and passive immunity are listed in Table 9.4.

BRIDGES BETWEEN INNATE AND ACQUIRED IMMUNITY

The innate and acquired immunity do not work independently; rather they function in a highly interactive and collaborative manner, increasing each other's efficiency and producing a combined response, which is more effective than either branch could produce by itself. Certain immune components play important roles in both types of immunity and are considered as bridges between innate and acquired immunity. Examples include:

- **Macrophages** and **dendritic cells** belong to innate immune system, but as antigen presenting cells, they present the antigenic peptides to T cells. More so, cytokines secreted from macrophages (interleukin-1) are also involved in T cell activation.
- **ADCC** (antibody dependent cell-mediated cytotoxicity) is a type of cell-mediated immune response (CMI) described in chapter 15, which involves both innate and adaptive components. Cells of innate immunity such as NK cell, eosinophils and neutrophils destroy the target cells which are coated with specific antibodies.
- **Complements** (classical pathway) are also part of both innate and adaptive immunity. They destroy the target cells which are coated with specific antibodies. However, alternate and mannose binding pathways do not take help of antibodies (Described in chapter 13).
- **Cytokines** secreted from cells of innate immunity can activate cells of adaptive immunity and vice versa. For example IL-1 secreted from macrophage activates helper T cells and interferon-γ secreted by helper T cell can activate macrophage.
- **Rare classes of lymphocytes** such as $\gamma\delta$ T cells, NK-T cells, B-1 cells and marginal-zone B cells: These cells have many characteristics that place them in the border of innate and acquired immunity.
  - They function in the early defense against microbes as part of innate immunity.
  - Although their receptors are encoded by somatic recombination of genes (similar to that of classical T and B cells), but these receptors have limited diversity.
  - They develop a memory phenotype in contrast to the property of innate immunity.

OTHER TYPES OF IMMUNITY

Local (or Mucosal) Immunity

Local or mucosal immunity is the immune response that is active at the mucosal surfaces such as intestinal or respiratory or genitourinary mucosa.

- It is usually mediated by a type of IgA antibody called secretory IgA, which prevents the entry of microbes at the local site itself.
- Local immunity can only be induced by natural infection or by live vaccination (but not by killed vaccines).
- **Example:** Following administration of live oral polio vaccine (OPV) or following infection with poliovirus; secretory IgA antibodies are synthesized and coated on intestinal mucosa which prevent subsequent poliovirus infections. Such immunity does not develop following injectable killed polio vaccine (IPV).

Herd Immunity

Herd immunity is defined as the overall immunity of a community (or herd) towards a pathogen.

- Herd immunity plays a vital role in preventing epidemic diseases. If the herd immunity is good, that means large

population of the community are immune towards a pathogen. Hence, epidemics are less likely to occur and eradication of the disease may be possible.

- Elements that contribute to create a strong herd immunity are:
  - Occurrence of clinical and subclinical cases in the herd.
  - On-going immunization programme
  - Herd structure, i.e. type of population involved
  - Type of pathogen-Herd immunity may not be strong in a community against all the pathogens.
- Herd immunity develops following effective vaccination against some diseases like:
  - Diphtheria and pertussis vaccine
  - Measles, mumps and rubella (MMR) vaccine
  - Polio (oral polio vaccine)
  - Smallpox vaccine

Adoptive Immunity

Adoptive immunity is a special type of cell-mediated immune response (CMI) which develops following injection of immunologically competent T-lymphocytes known as **transfer factor**. It is useful for treatment when the CMI is low, e.g. in lepromatous leprosy.

EXPECTED QUESTIONS

I. Essay:

1. Define immunity. Describe in detail about the properties and mediators of innate immunity.

II. Write short notes on:

1. Herd immunity
2. Differences between innate and acquired immunity
3. Differences between active and passive immunity

III. Multiple Choice Questions (MCQs):

1. Which is not a mediator of innate immunity?
   a. T cells
   b. NK cell
   c. T/NK cells
   d. Neutrophil

2. Which of the following about innate immunity is wrong?
   a. Immune response occurs in minutes
   b. Non-specific
   c. First line of defense
   d. Need prior contact with the antigen

3. Which of the following about active immunity is correct?
   a. No lag phase
   b. Booster doses are useful
   c. Useful in immunodeficient people
   d. No memory cells

4. Primary immune response—the correct statement is:
   a. Involves IgG
   b. Antibody producing cells- Memory B cell
   c. No lag period
   d. Slow and sluggish

Answers

1. a **2.** d **3.** b **4.** d

CHAPTER 10

Antigen

Chapter Preview

- Antigen and hapten
- Antigen and host relationship
- Factors influencing immunogenicity
- Biological classes of antigens

ANTIGEN

Antigen is defined as any substance that satisfies two distinct immunologic properties—immunogenicity and antigenicity.

1. **Immunogenicity:** It is the ability of an antigen to induce immune response in the body (both humoral and/or cell mediated).
   - B cells + antigen → effector B cells (plasma cell) + memory B cells
   - T cells + antigen → effector T cells (helper T cell or cytotoxic T cell) + memory T cells
2. **Antigenicity (immunological reactivity):** It is the ability of an antigen to combine specifically with the final products of the above two responses (i.e., antibodies and/or T cell-surface receptors).

The substance that satisfies the first property, i.e. immunogenicity (inducing specific immune response) is more appropriately called **"immunogen"** rather than using the word "antigen".

All molecules having immunogenicity property, also show antigenicity, but the reverse is not true (e.g. haptens—which are antigenic, but not immunogenic).

Epitope

Epitope or antigenic determinant is the smallest unit of antigenicity.

- It is defined as a small area present on the antigen comprising of few (four to five) amino acids or monosaccharide residues, that is capable of sensitizing T and B cells and reacting with specific site of T cell receptor or an antibody.
- The specific site of an antibody that reacts with the corresponding epitope of an antigen is called **paratope**.

Epitopes may be grouped into two types:

1. **Sequential** or **linear epitope:** It presents as a single linear sequence of few amino acid residues.
2. **Conformational** or **non sequential** epitopes are found on the flexible region of complex antigens having tertiary structures. They are formed by bringing together the surface residues from different sites of the peptide chain during its folding into tertiary structure.

In general, T cells recognize sequential epitopes, while B cells bind to the conformational epitopes.

HAPTEN

Haptens are low molecular weight molecules that **lack immunogenicity** (cannot induce immune response) but **retain antigenicity or immunological reactivity** (i.e. can bind to their specific antibody or T cell receptor). Haptens can become immunogenic when combined with a larger protein molecule called **carrier**.

The hapten-carrier complex is capable of inducing immune response in the body. It is observed that animals immunized with such a hapten-carrier conjugate produce antibodies specific for:

- Epitopes of hapten
- Unaltered epitopes on the carrier protein
- New epitopes formed by combined parts of both the hapten and carrier (Fig. 10.1).

Haptens may be classified as complex or simple:

- **Complex haptens** contain two or more epitopes; they can react with specific antibodies and the hapten-antibody complex can be visualized by various methods such as precipitation reaction.
- **Simple haptens** usually contain only one epitope (univalent). Such haptens can bind to the antibodies but the hapten antibody complex cannot be visualized, as it is believed that precipitation to happen, it requires the antigen to have at least two or more epitopes.

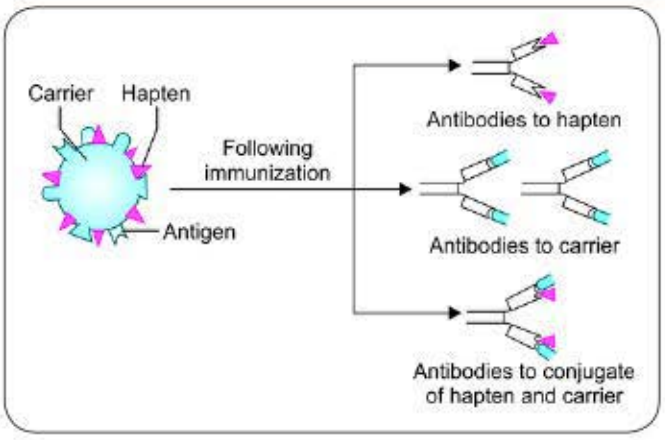

Fig. 10.1: Types of antibodies produced against a hapten-carrier conjugate

ANTIGEN-HOST RELATIONSHIP

Based on the antigen-host relationship, antigens can be grouped into two groups as follows:

1. **Self or auto antigens:** They belong to the host itself; hence they are not immunogenic. Hosts do not react to their own antigens by exhibiting a mechanism called **immunological tolerance** (chapter 17). However, sometimes, the self-antigens are biologically altered (e.g. as in cancer cells) and can become immunogenic.
2. **Non-self or foreign antigens:** They are immunogenic and are of three types based on their phylogenetic distance to the host.
   - **Alloantigens** are species specific. Tissues of all individuals in a species contain species-specific antigens.
   - **Isoantigens** are type of antigens which are present only in subsets of a species, e.g. blood group antigens and histocompatibility antigens. The histocompatibility antigens are highly specific as they are unique to every individual of a species.
   - **Heteroantigens:** Antigens belonging to two different species are called heteroantigens, e.g. antigens of plant or animal or microorganisms, etc. A **heterophile antigen** is a type of heteroantigen that exists in unrelated species (explained below).

Heterophile Antigens

Heterophile antigens are a type of heteroantigens that are present in two different species; but they share epitopes with each other. Antibody produced against antigen of one species can react with the other and vice versa.

Contd...

Contd...

Diagnostic Application

Heterophile antigens can be used in various serological tests. Antibody against one antigen can be detected in patient's serum by employing a different antigen which is heterophile (cross reactive) to the first antigen. For example-

- **Weil-Felix reaction** is done for typhus fever. Antibodies against rickettsial antigens are detected by using cross reacting *Proteus* antigens.
- **Paul-Bunnell test** is done for infectious mononucleosis (caused by Epstein-Barr virus). Here, sheep red blood cell (RBC) antigens are used to detect cross-reacting antibodies in patient's sera.
- **Cold agglutination test** and *Streptococcus* MG test are done for primary atypical pneumonia. Here, antibodies against *Mycoplasma pneumoniae* are detected by using human O blood group RBC and *Streptococcus* MG antigens respectively.

FACTORS INFLUENCING IMMUNOGENICITY

There are various factors that influence immunogenicity of an antigen.

- **Size of the antigen:** Larger is the size; more potent is the molecule as an immunogen. It is found that molecules of more than 10,000 Dalton molecular weight only can induce immune response (e.g. hemoglobin). Substances of molecular weight between 5000-10,000 Dalton are poor immunogens (e.g. insulin).
- **Chemical nature of the antigen:** Proteins are stronger immunogens than carbohydrates followed by lipids and nucleic acids.
- **Susceptibility of antigen to tissue enzymes:** Only substances that are susceptible to the action of tissue enzymes are immunogenic. Degradation of the antigen by the tissue enzymes produces several immunogenic fragments having more number of epitopes exposed. Molecules that are not susceptible to tissue enzymes such as polystyrene latex or synthetic polypeptides composed of **D-amino acids** are not antigenic; while polypeptides consisting of **L-amino acids** are antigenic as they are degradable by tissue enzymes. However, substances very rapidly broken down by tissue enzymes may not be immunogenic as that may denature the epitopes.
- **Structural complexity:** Simple homopolymers made up of single amino acid lack immunogenicity. Polymers made up of two or more amino acids are immunogenic. More so, addition of aromatic amino acids increases immunogenicity. Complex proteins containing 20 amino acids and with four level of structural organization are strongly immunogenic; e.g. hemoglobin.

- **Foreignness to the host:** This is one of the key factor which determines immunogenicity. Higher is the phylogenetic distance between the antigen and the host; more is the immunogenicity.
  - Self-antigens are not immunogenic; whereas, heteroantigens and alloantigens are immunogenic; the degree of immunogenicity increases with the distance.
    - Plant antigens are more immunogenic than animal antigens to humans.
    - Bovine serum albumin is more immunogenic to chicken than to goat.
  - Isoantigens are not immunogenic to those individuals who possess these antigens; but for other individuals they are immunogenic.
- **Genetic factor:** Different individuals of a given species show different types of immune responses towards the same antigen. This is believed to be due to the genetic differences between the individuals.
  - Responders are the individuals who produce antibody faster.
  - Slow responders are the individuals who produce antibody slowly and may need repeated antigenic exposures.
  - Non-responders are the individuals who do not produce antibody in spite of repeated antigenic exposures.
- **Optimal dose of antigen:** An antigen is immunologically active only in the optimal dose range. A too little dose fails to elicit immune response and a too large dose leads to development of immunological tolerance (chapter-17), a phenomenon previously designated by Felton as **immunological paralysis**.
- **Route of antigen administration:** In general, the immune response is better induced following parenteral administration of an antigen; however it also depends on the type of antibody produced.
  - Immunoglobulin A (IgA) are better induced following oral administration of antigens.
  - Inhalation of pollen antigens induces IgE synthesis; whereas the same antigens given parenterally lead to formation of IgG antibodies.
  - **Site of injection** may influence immunogenicity- The hepatitis B vaccine is more immunogenic following deltoid injection than gluteal injection. This may be due to the paucity of antigen presenting cells (APCs) in gluteal fat.
- **Repeated doses of antigens:** Repeated doses of antigens over a period of time are needed to generate an adequate immune response. This is due to the role of memory cells in secondary immune response. However, after a certain doses of antigens, no further increase in antibody response is seen.
- **Multiple antigens:** When two or more antigens are administered simultaneously, the effects may vary. The antibody response to one or the other antigen may be equal or diminished (due to antigenic competition) or enhanced (due to adjuvant like action, see below highlight box).

Adjuvant

The term "adjuvant" refers to any substance that enhances the immunogenicity of an antigen. They are usually added to vaccines to increase the immunogenicity of the vaccine antigen.

Examples of Adjuvant Activity

- **Alum** (aluminium hydroxide or phosphate)
- **Mineral oil** (liquid paraffin)
- **Freund's incomplete adjuvant:** It is a water-in-oil emulsion containing a protein antigen in the aqueous phase.
- **Freund's complete adjuvant** is the mixture of Freund's incomplete adjuvant and suspension of killed tubercle bacilli in the oil phase.
- **Lipopolysaccharide** (LPS) fraction of gram-negative bacilli- e.g. LPS of *Bordetella pertussis* acts as an excellent adjuvant for diphtheria and tetanus toxoids. This explains the reason for using combined immunization for diphtheria, pertussis and tetanus in the form of DPT vaccine.
- **Other bacteria or their products:**
  - *Mycobacterium bovis*
  - Toxoid (diphtheria toxoid and tetanus toxoid act as adjuvant for *Haemophilus influenzae*-type b vaccine)
- Nonbacterial products: Such as silica particles, beryllium sulfate, squalene and thimerosal.

Mechanism of Adjuvant Action

Adjuvants act through the following steps:

- **Delaying the release of antigen:** Adjuvant on mixing, precipitate the antigen which is then released slowly from the site of administration, thus prolonging the antigenic exposure.
- **By activating phagocytosis:** The adjuvant-antigen precipitate is of larger size, thus increases the likelihood of phagocytosis. The MDP (muramyl dipeptide) component of tubercle bacilli can activate the macrophages directly.
- **By activating T_H cells:** Activated macrophages release interleukin-11 (IL-11) and express higher level of MHC-II; thus promoting helper T (T_H) cell activation which in turn activates B cells to produce specific antibodies.
- **By granuloma formation:** Certain adjuvants such as Freund's complete adjuvant causes chronic inflammation and granuloma formation at the inoculation site (hence not suitable for human use). Activated phagocytes in granuloma continue to enhance T_H cell activation.

- **Effect of prior administration of antibody:** The immune response against a particular antigen is suppressed if its corresponding antibody was administrated prior to that.
  - The primary immune response is more susceptible to get suppressed than the secondary immune response.

- **Therapeutic application:** In Rh negative women carrying an Rh positive fetus, the anti-Rh globulin is administrated immediately following delivery (within 72 hours) which prevents the Rh sensitization in Rh negative women by a negative feedback mechanism.

BIOLOGICAL CLASSES OF ANTIGENS

Depending on the mechanisms of inducing antibody formation, antigens are classified as T cell dependent (TD) and T cell independent (TI) antigens (Table 10.1).

T Dependent (TD) Antigens

Most of the normal antigens are T cell dependent, they are processed and presented by antigen-presenting cells (APCs) to T cells which leads to T cell activation. The activated T cells secrete cytokines that in turn stimulate the B cells to produce antibodies.

T Independent (TI) Antigens

There are a few antigens such as **bacterial capsule, flagella** and **LPS** (lipopolysaccharide) that do not need the help of T cells and APCs. They directly bind to immunoglobulin receptors present on B cells and stimulate B cells polyclonally. It leads to increased secretion of non-specific antibodies hypergammaglobulinemia.

- TI antigens can activate both mature and immature B cells. B cells can only differentiate into activated cells. There is no memory cells formation.
- Activated B cells do not undergo affinity maturation and class switch over (both properties are unique to TD antigen stimulated B cells); thus such an activated B cell can produce only limited classes of antibodies such as IgM and IgG3.

Detailed mechanism of B cell activation against TD antigen is given in chapter15.

Superantigens

Superantigens are the third variety of biological class of antigens, recently described in the last decade. The unique feature of superantigens is, they can activate T cells directly without being processed by antigen-presenting cells (APCs).

- The variable β region of T cell receptor (vβ of TCR) appears to be the receptor for superantigens.
- They directly bridge non-specifically between major histocompatibility complex (MHC)-II of APCs and T cells (Fig. 10.2).
- Non-specific activation of T cells leads to massive release of cytokines which can activate B cell polyclonally, which leads to increased secretion of non- specific antibodies (hypergammaglobulinemia).

Examples of Superantigens

Various products of microorganisms behave as superantigens; the most important being staphylococcal and streptococcal toxins. (Table 10.2).

TABLE 10.1: Differences between T independent antigens and T dependent antigen

T Independent Antigen	T dependent Antigen
Structurally simple—LPS, capsular polysaccharide, flagella	Structurally complex—protein in nature
Dose dependent Immunogenicity	Immunogenic over wide range of dose
No memory	Memory present
No antigen processing	Antigen processing step is needed
Slowly metabolized	Rapidly metabolized
Activate B cells polyclonally	Activate B cells monoclonally
Activate both mature and immature B cells	Activate mature B cells only
B cells stimulated against T independent antigen do not undergo ▪ Affinity maturation ▪ Class switch over	B cells stimulated against T dependent antigen undergo ▪ Affinity maturation ▪ Class switch over
Antibody response is restricted to IgM and IgG3	Antibodies of all classes can be produced

Abbreviation: LPS, lipopolysacchrides; IgM, immunoglobin M

TABLE 10.2: Superantigens

Bacterial superantigen
Staphylococcal toxin: ▪ Toxic shock syndrome toxin-1 (TSST-1) ▪ Exfoliative toxin ▪ Enterotoxins
Streptococcal pyrogenic exotoxin (SPE)-A and C
Mycoplasma arthritidis mitogen-I
▪ *Yersinia enterocolitica* ▪ *Yersinia pseudotuberculosis*
Viral superantigen
Epstein-Barr virus associated superantigen
Cytomegalovirus associated superantigen
Rabies nucleocapsid
HIV encoded superantigen (nef- negative regulatory factor)
Fungal superantigen
Malassezia furfur

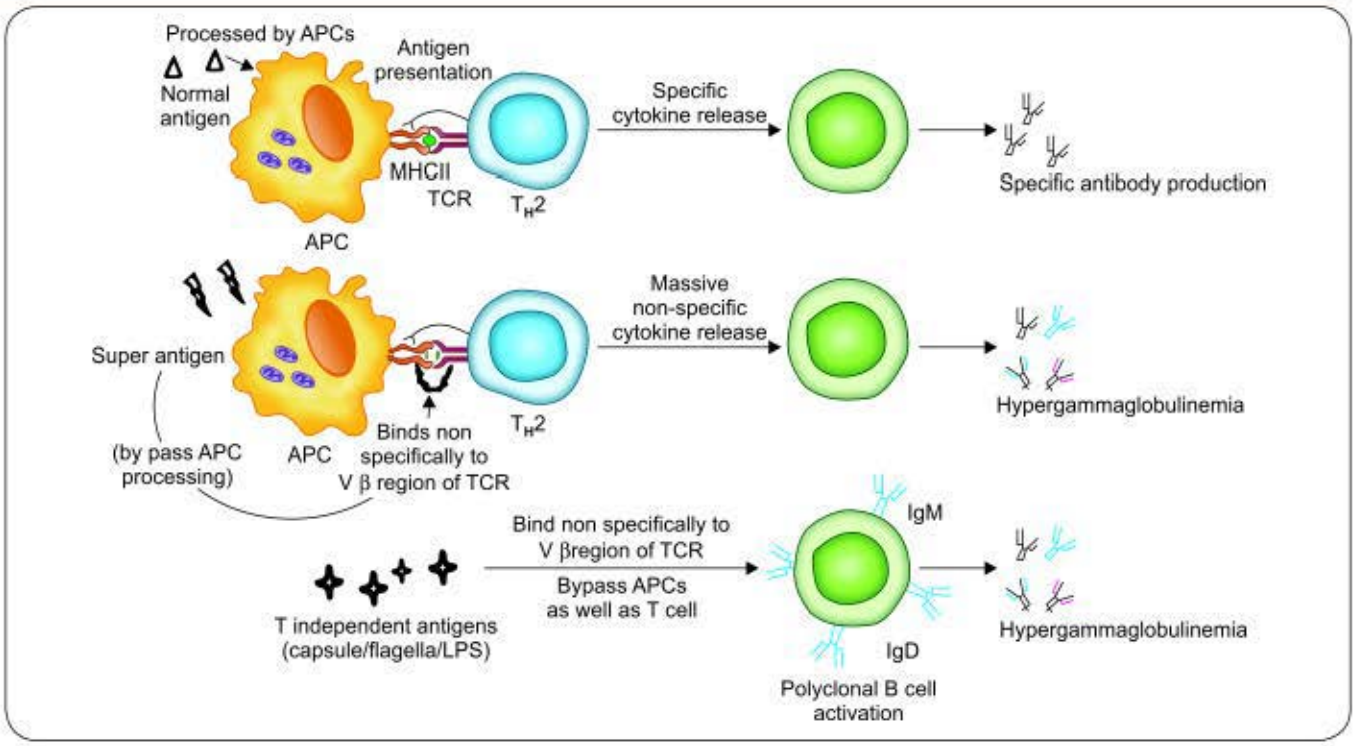

Fig. 10.2: Mechanism of action of superantigens

Abbreviation: APCs, antigen-presenting cells; TCR, T cell receptor; MHC, major histocompatibility complex

Disease Associated with Superantigens

Superantigens can cause a number of diseases. The conditions associated with staphylococcal toxins are as follows:

- Toxic shock syndrome
- Food poisoning
- Scalded skin syndrome
- Rare conditions such as—atopic dermatitis, Kawasaki syndrome, psoriasis, acute disseminated encephalomyelitis.

EXPECTED QUESTIONS

I. Write short notes on:

1. Epitope
2. Hapten
3. Heterophile antigens
4. Adjuvant
5. T independent antigen
6. Superantigens

II. Multiple Choice Questions (MCQs):

1. Superantigen causes:
   a. Enhancement of phagocytosis
   b. Polyclonal activation of B cells
   c. Antigen presentation by macrophage
   d. Activation of complement

2. Which part of the bacteria is mostly antigenic?
   a. Protein
   b. Carbohydrate
   c. Lipid
   d. Nucleic acid

3. Which of the following statements is true about hapten?
   a. It induces immune response
   b. It is a T independent antigen
   c. It needs carrier to induce immune response
   d. It has no association with MHC

Answers

1. b **2.** a **3.** c

CHAPTER 11

Antibody

Chapter Preview

- Structure of antibody
- Immunoglobulin classes
- Antigenic determinants of immunoglobulins
- Monoclonal antibody
- Genetics of antibody production

Antibody or immunoglobulin is a specialized glycoprotein, produced from activated B cells (plasma cells) in response to an antigen, and is capable of combining with the antigen that triggered its production.

- It was found that (*A. Tiselius,* 1939) when the serum is subjected to electrophoresis, the serum proteins are separated into four fragments—albumin, globulin α, β and γ (Fig. 11.1). Antibodies are located in the γ-globulin fraction. Because they immunologically react with the antigen, they were given the name as immunoglobulin.
- Both the terms, immunoglobulin (Ig) and antibody are used interchangeably, representing the physiological and functional properties of same molecule respectively.
- Immunoglobulin (Ig) constitutes 20–25% of total serum proteins.
- There are five classes (or isotypes) of immunoglobulins recognized—IgG, IgA, IgM, IgD and IgE.

STRUCTURE OF ANTIBODY

An antibody molecule is a 'Y-shaped' heterodimer, composed of four polypeptide chains (Fig. 11.2).

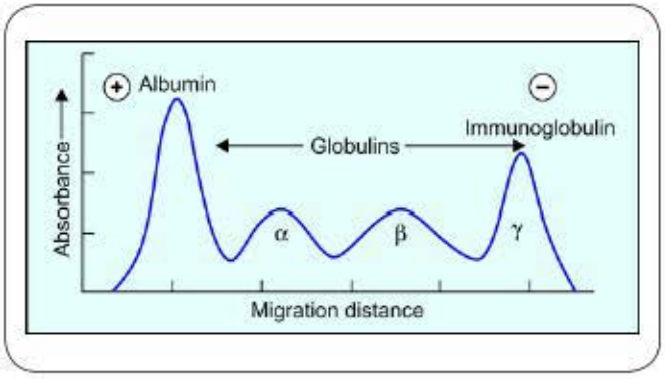

Fig. 11.1: Electrophoresis of human serum proteins

- Two identical light (L) chains, of molecular weight 25,000 Da each and
- Two identical heavy (H) chains each having molecular weight 50,000 Da or more.

H and L Chain

All four H and L chains are bound to each other by disulfide bonds, and by noncovalent interactions, such as salt linkages, hydrogen bonds, and hydrophobic bonds.

- All the chains have two ends—an amino terminal end (NH_3) and a carboxyl terminal end (COOH).
- There are five classes of H chains and two classes of light chains.

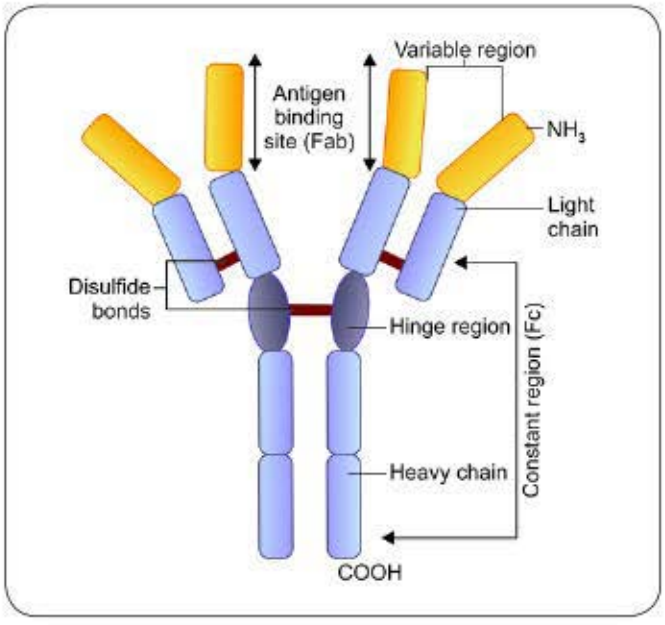

Fig. 11.2: General structure of antibody

TABLE. 11.1: Type of heavy chain in each immunoglobulin class

Immunoglobulin class	Heavy chain type
IgG	γ (gamma)
IgA	α (alpha)
IgM	μ (mu)
IgD	δ (delta)
IgE	ε (epsilon)

- The five classes of H chains are structurally and antigenically distinct; each is designated by the Greek letters γ, α, μ, δ and ε and is present only in a particular class of Ig.
- The five classes of immunoglobulins (lgG, IgA, IgM, IgD and IgE) are classified based on the amino acid sequences of the heavy chains (Table 11.1).
- The L chains are of two types—kappa (κ) and lambda (λ), named after Korngold and Lapari who originally described them.
  - In humans, 60% of the light chains are kappa and 40% are lambda type (ratio 3:2).
  - Both the light chains of an antibody molecule should be of same type, either κ or λ, but never both.
- L chains are composed of 214 amino acids; whereas the number of amino acids in the heavy chain varies—ranging from 446 (in α chain) to 576 (in μ chain).

Variable and Constant Regions

Each H and L chain comprises of two regions—variable and constant region, depending upon whether the amino acid sequences of the regions show variable or uniform pattern among different antibodies.

Variable Region

The first 110 amino acid residues near the amino terminal end (NH_3) of both L and H chains constitute the variable region—designated as V_L and V_H, respectively. It represents the antigen binding site of the antibody.

- **Hypervariable region:** Within the variable region, there are some zones (**hot spots**) that show relatively higher variability in the amino acid sequences. Such zones are called as hypervariable regions or complementarity determining regions (CDRs). They form the antigen—binding site. There are three hot spots in the L and four in the H chain, respectively.
- **Paratope:** The site on the hypervariable regions that make actual contact with the epitope of an antigen is called as paratope.

Constant Region

It constitutes the remaining part of an Ig molecule other than that of variable region. The length of the constant regions is approximately 104 amino acids for light chain, 330 amino acids for γ, α and δ heavy chains and 440 amino acids for μ and ε heavy chains. The amino acid sequence of constant region shows uniform pattern. A single antibody molecule has two identical heavy chains and two identical light chains; H_2L_2.

H and L Chain Domains

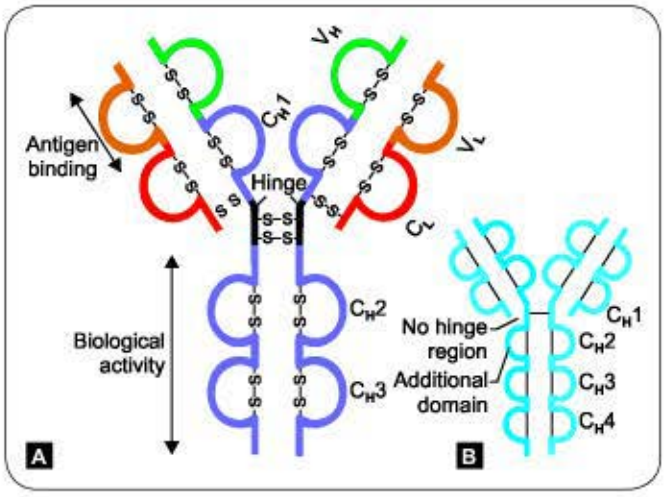
Heavy and light chains are further folded into domains, each containing about 110 amino acid residues. Within the domain, a loop like structure of 60 amino acids is present which is formed due to an intrachain disulfide bond. The number of domains in each chain varies:

- Light chain contains one variable domain (V_L) and one constant domain (C_L).
- Heavy chains possess one variable domain (V_H) and 3 or 4 numbers of constant domain (C_H):
  - Heavy chains γ, α and δ have three constant domains-C_H1, C_H2 and C_H3 (Fig. 11.3A).
  - Heavy chains μ and ε have four constant domains-C_H1 to C_H4 (Fig. 11.3B).

Hinge Region

In heavy chain (γ, α, and δ), the junction formed between C_H1 and C_H2 domain constitutes the hinge region (Fig. 11.3A).

- This region is rich in proline and cysteine. The hinge region is quite flexible, allowing the Ig molecule to assume different positions, thus helps the antibody in reaching towards the antigen.
- In IgE and IgM, the ε and μ heavy chains do not have hinge region; instead, their constant region has an additional domain (C_H4) (Fig. 11.3B).
- The hinge region is sensitive to various enzymatic digestions.



Figs 11.3A and B: Immunoglobulin domains. **A.** Ig with γ, δ and α heavy chains; **B.** Ig with μ and ε heavy chains

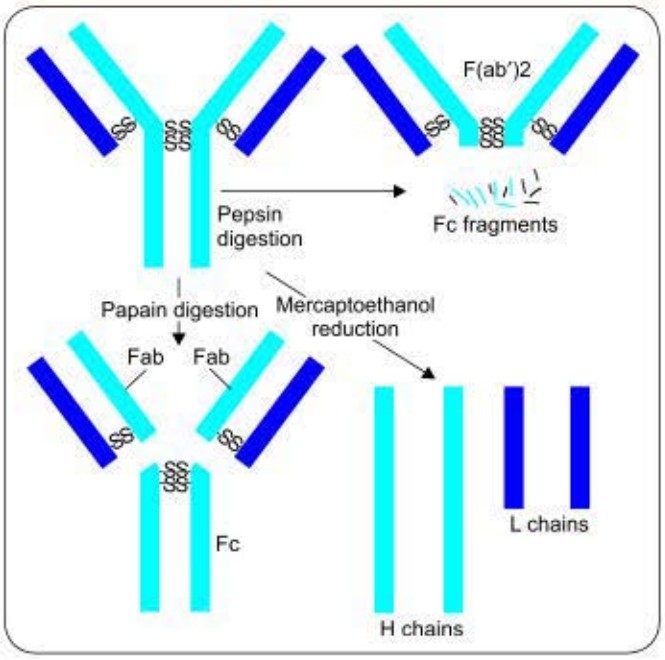


Fig. 11.4: Enzymatic digestion of immunoglobulin

Enzymatic Digestion

When an immunoglobulin molecule is subjected to enzymatic digestion, it generates various fragments (Fig. 11.4).

- **Papain digestion:** Papain cleaves the Ig molecule at a point above the disulfide bridge of hinge region; resulting in three fragments each having a sedimentation coefficient of 3.5 S:
  - **Two Fab fragments:** Soluble fragments which bind to the antigen (Fab for antigen binding fragment) and
  - **Fc fragment:** An insoluble fraction which gets crystallised in the cold (Fc for crystallisable fragment).
- **Pepsin digestion**: Pepsin cleaves the Ig molecule at a point below the disulphide bridge of hinge region; resulting in formation of:
  - **One F $(ab')_2$ fragment:** A fragment having a sedimentation coefficient of 5S; composed of two Fab subunits bound together.
  - **Many smaller fragments:** Due to digestion of Fc portion by pepsin into smaller fragments.
- **Mercaptoethanol** reduction of Ig molecule—generates four fragments (two H and two L chains) as it cleaves only disulfide bonds sparing the peptide bonds.

FUNCTIONS OF IMMUNOGLOBULINS

Antigen Binding (by Fab Region)

Binding to the antigen is the primary function of an antibody which can result in protection of the host.

- The Fab fragment bears the variable region and is involved in interaction with the antigen.
- The valency of an antibody refers to the number of Fab regions it possesses. Thus, a simple monomeric antibody molecule has a valency of two.

Effector Functions (by Fc Region)

Most of the times, the binding of an antibody to its antigen does not result in any direct biological effect. Rather, variety of secondary "effector functions" are produced; mediated by Fc region of the antibody. These effector functions include:

- **Fixation of complement:** Antibody coating the target cell binds to complement through its Fc receptor which leads to complement mediated lysis of the target cell.
- **Binding to various cell types:** Phagocytes, lymphocytes, platelets, mast cells, NK cell, eosinophils and basophils bear Fc receptors (FcR) that bind to Fc region of immunoglobulins. This binding can activate the cells to perform some biological functions (described with individual immunoglobulins and also in Chapter 15). Some immunoglobulins (e.g. IgG) also bind to receptors on placental trophoblasts, which results in transfer of the IgG across the placenta.

IMMUNOGLOBULIN CLASSES

Based on five types of heavy chains, there are five classes of immunoglobulins (IgG, IgA, IgM, IgD and IgE). Each class can also exist as two types due to presence of different light chain type—kappa or lambda. IgG and IgA are further divided into subclasses (four for IgG and two for IgA) due to minor differences in amino acid sequences in constant region of heavy chains. Important properties of different Ig classes are summarized in Table 11.2.

Immunoglobulin G (IgG)

It constitutes about 70–80% of total Ig in the body.

- Among all Ig, IgG has maximum daily production, longest half-life of 23 days and highest serum concentration.
- **IgG has four subclasses:** IgG1, IgG2, IgG3 and IgG4; all differ from each other in the amino acid sequences of the constant region of their γ-heavy chain.
- The subclasses vary in their biological functions, length of hinge region and number of disulfide bridges. IgG3 has longest hinge region with 11 interchain disulfide bonds.

Functions of IgG

- IgG can **cross placenta**; hence provide immunity to the fetus and new born. Among subclasses, IgG2 has the poorest ability to cross placenta.

TABLE 11.2: Properties of various immunoglobulins

Property	IgG	IgA	IgM	IgD	IgE
Usual form	Monomer	Monomer, dimer	Monomer, pentamer	Monomer	Monomer
Valency	2	2 or 4	2 or 10	2	2
Other chains	None	J chain, secretory component	J chain	None	None
Subclasses	G1, G2, G3, G4	A1, A2	None	None	None
Molecular weight (kDa)	150	150–600	900	150	190
Serum level (mg/mL)	9.5–12.5	IgA 1–3.0 IgA 2–0.5	1.5	0.03	0.0003
% of total serum Ig	75–85%	10–15%	5–10%	0.3%	0.019%
Half-life, days	23*	6	5	3	2.5
Daily production (mg/kg)	34	24	3.3	0.4	0.0023
Intravascular distribution (%)	45	42	80	75	50
Sedimentation coefficient	7	7	19	7	8
Complement activation					
Classical	++ (IgG3>1>2)	–	+++	–	–
Alternate	–	+	–	–	–
Binds to Fc receptors of phagocytes	++	–	?**	–	–
Placental transfer	Yes (except IgG2)	–	–	–	–
Mediates coagglutination	Yes (except IgG3)	–	–	–	–
Mucosal transport	–	Yes	–	–	–
Mast cell degranulation	–	–	–	–	yes
Marker for B cells	–	–	+	+	–
Heat stability	+	+	+	+	–

*Half-life of IgG3 is 8 days; **?- Questionable

- **Complement fixing:** Fc region of IgG can bind to complement factors; thus activates the classical pathway of complement system. The complement fixing ability of subclasses varies—IgG3> IgG1> IgG2. IgG4 does not fix complements.
- **Phagocytosis:** IgG1 and IgG3 bind to Fc receptors present on phagocytes (macrophages, neutrophils) with high affinity and enhances the phagocytosis (opsonization) of antigen bound to it. IgG2 has an extremely low affinity for Fc receptors of phagocytes.
- It mediates precipitation and neutralization reactions.
- IgG plays a major role in neutralization of toxins as it can easily diffuse into extravascular space.
- IgG is raised after long time following infection and represents chronic or past infection (recovery).
- **Coagglutination:** IgG subclasses (except IgG3) mediates coagglutination reaction by binding protein-A of *S. aureus* (Chapters 12 and 21).

Immunoglobulin M (IgM)

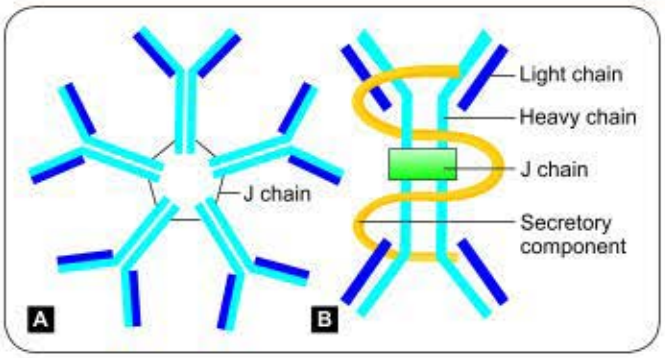
Among all Ig, IgM has highest molecular weight, and maximum sedimentation coefficient (19S). It is present only in intravascular compartment, not in body fluids or secretions.

IgM exists in both monomeric and pentameric forms:

- When present as membrane-bound antibody on B cells, it exists in monomeric form.
- When present in secreted form, it is pentameric in nature; i.e. five IgM monomeric units are joined with each other (by J chain) to form a complete IgM pentamer having 10 Fab regions and 10 valencies (Fig. 11.5A).

Functions of IgM

- **Acute infection:** IgM is the first antibody to be produced following an infection; represents acute or recent infection. It is also called as primary immune response antibody.
- **Complement fixing:** It is the most potent activator of classical complement pathway due to multiple complement binding sites (5 Fc regions) present in IgM pentamer.
- It is also present on B cell surface in monomeric form and serves as B cell receptor for antigen binding.
- It acts as an **opsonin**; binds to antigen which is then easily recognized and removed. IgM is 500–1000 times more potent in opsonization than IgG.



Figs 11.5A and B: **A.** Pentameric IgM; **B.** Dimeric IgA

- **Fetal immunity:** It is the first antibody to be synthesized in fetal life (20 weeks); thus provides immunity to the fetus. Presence of IgM in fetus or newborn indicates intrauterine infection and its detection is useful in diagnosis of congenital infections.
- **Protection against intravascular organisms:** IgM being intravascular, is responsible for protection against blood invasion by microorganisms. IgM deficiency is often associated with septicemia.
- **Mediate agglutination:** IgM is about 20 times more effective in bacterial agglutination than IgG.

Immunoglobulin A (IgA)

IgA is the second most abundant class of Ig next to IgG, constituting about 10–15% of total serum Ig. It exists in both monomeric and dimeric forms (Fig. 11.5B).

Serum IgA

- IgA in serum is predominantly in monomeric form.
- Functions: Serum IgA interacts with the Fc receptors expressed on immune effector cells, to initiate various functions such as antibody-dependent cell-mediated cytotoxicity (ADCC), degranulation of immune cells, etc.

Secretory IgA

Secretory IgA is dimeric in nature; the two IgA monomeric units are joined by **J chain.** In addition, there is another joining segment present between two IgA molecules called **secretory component**.

- **Location:** Secretory IgA is the predominant antibody found in body secretions like milk, saliva, tears, intestinal and respiratory tract mucosal secretions.
- The secretory component is derived from poly-Ig receptor present on the serosal surfaces of the epithelial cells.
- **Function:** The secretory IgA mediates **local or mucosal immunity**; provides protection against pathogens by cross-linking bigger antigens with multiple epitopes and preventing their entry through the mucosal surface.
- It is effective against bacteria like *Salmonella, Vibrio, Neisseria,* and viruses like polio and influenza.
- Breast milk is rich in secretory IgA and provides good protection to the immunologically immature infant gut.

Secretory IgA

The dimeric secretory IgA is synthesised by plasma cells situated near mucosal epithelium. The J chain is also produced in the same cell.

Whereas, the secretory component is synthesized by the mucosal epithelial cells.

- It is derived from the poly-Ig receptor present on the basolateral surfaces of the epithelial cells.
- It helps the dimeric IgA to cross the epithelial surface to reach the lumen.
- It also protects IgA from denaturation by bacterial proteases produced by intestinal flora.

Subclasses of IgA

Depending upon the amino acid sequences in the constant region of heavy chain, IgA exists in two isotypes:

1. IgA1 is the dominant subclass in serum. Serum IgA comprises of ~ 90% IgA1 and 10% IgA2.
2. IgA2 percentages are higher in secretions than in serum (ranging from 10% to 20% in nasal and male genital secretions, 40% in saliva, to 60% in colonic and female genital secretions).
   - IgA2 lacks the disulphide bonds between the heavy and light chains.
   - Polysaccharide antigens tend to induce more IgA2 synthesis than protein antigens.

Immunoglobulin E (IgE)

Among all Ig, IgE is having the lowest serum concentration, shortest half-life and minimum daily production. It is also the only heat labile antibody (inactivated at 56°C in one hour). It has affinity for the surface of tissue cells (mainly mast cells) of the same species (homocytotropism). It is mainly extravascular in distribution.

Functions of IgE

- IgE is highly potent and mediate **type I hypersensitivity** reactions by binding to the mast cells causing its degranulation. IgE response is seen in various allergic conditions, such as asthma, anaphylaxis, hay fever, etc. (Described in detail in Chapter 16).
- IgE is elevated in **helminthic infections**. By coating on the surface of eosinophils, IgE stimulates the release of the mediators on to the surface of helminths by a process known as antibody mediated cellular cytotoxicity or ADCC (Chapter 15).

Immunoglobulin D (IgD)

IgD is found as membrane Ig on the surface of B cells and acts as a B cell receptor along with IgM. It has the highest carbohydrate content among all the immunoglobulin. No other function is known for IgD so far.

ANTIGENIC DETERMINANTS OF IMMUNOGLOBULINS

Since antibodies are glycoproteins, they can themselves function as potent immunogens, having a number of antigenic determinants which can induce antibody responses in hosts other than the parent host. It is observed that the entire Ig molecule is not immunogenic, but it contains antigenic determinants at specific sites. Based on the location of antigenic determinants, the Ig molecules are divided into, isotypes, idiotypes and allotypes (Fig. 11.6).

Isotypes

The five classes of Ig (IgG, IgA, IgM, IgD and IgE) and their subclasses are called as isotypes; they vary from each other in the amino acid sequences of the constant region of their heavy chains. Such variation is called as isotypic variation.

- Isotypes that are present in all members of a given species are similar in nature.
- Hence, antibody against isotypes can be produced by injecting the Ig from one species into another.

Idiotypes

The unique amino acid sequence present in paratope region (in V_H and V_L regions) of one member of a species acts as antigenic determinant to other members of the same species.

- Such antigenic determinants are called as idiotopes and the sum total of idiotopes on an Ig molecule constitutes its idiotypes.

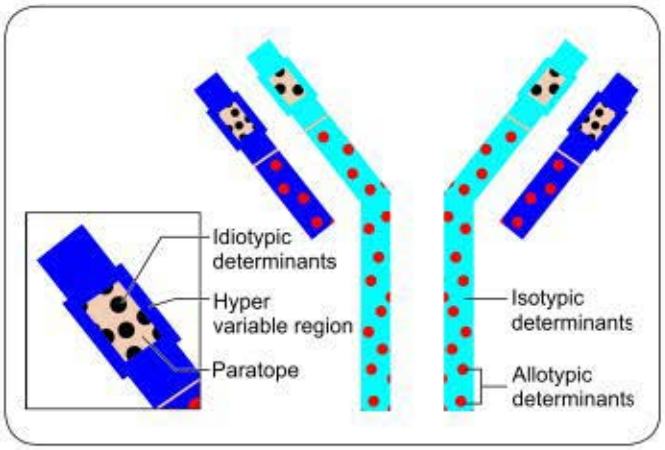


Fig. 11.6: Antigenic determinants of immunoglobulins

- Such variation between immunoglobulins due to differences in the amino acid sequences of the variable region is called as idiotypic variation.
- Idiotypes in an individual arise continuously from mutations (somatic hypermutations) in the genes of variable region. Hence, idiotypes may act as foreign to the host itself; however, do not evoke autoimmune response because they are present in small numbers.

Allotypes

The antigenic determinants present in the isotype genes in the constant region of H and L chains, encoded by multiple alleles are called as allotypes.

- Although all members of a species inherit the same set of isotype genes, multiple alleles exist for some of the allele genes.
- Hence, allotypes are present in the constant region of Ig molecules of the same class, in some, but not all, members of a species.
- The sum of the individual allotypic determinants displayed by an antibody determines its allotype.
- Allotypes differ in sequence of 1–4 amino acid from one another.
- **Allotype systems:** To date, three systems of allotypic markers have been characterized for humans:
  - For kappa light chain (Km system)—has three Km allotypes
  - For γ heavy chain (Gm system)—has 25 Gm types
  - For α heavy chain (Am system)

Antibody to allotype determinants can be produced by injecting antibodies containing these determinants from one member to another within a given species. Anti allotype specific antibodies may also be developed following blood transfusion or by maternal passage of IgG into the fetus.

ABNORMAL IMMUNOGLOBULINS

In addition to the five classes of normal antibodies, other structurally similar proteins are seen in sera of patients and sometimes even in healthy individuals.

Bence Jones Proteins

They are produced in a neoplastic condition of plasma cells called multiple myeloma.

- This condition is also called as light chain disease as the cancerous plasma cells produce excess of light chain (Bence Jones proteins) which are accumulated in patient's serum and excreted in urine.
- Such proteins have a unique property of getting coagulated at 50°C and redissolving again at 70°C.

Waldenstrom's Macroglobulinemia

It is a B cell lymphoma, producing excess IgM. It has been seen in multiple myeloma. Somatic mutations in MYD88 gene occur in over 90% of patients.

Heavy Chain Disease

It is characterized by an excessive production of heavy chains that are short and truncated. Four types of heavy chain disease have been recognized based on H chain involved:

1. α chain disease (Seligmann's disease)
2. γ chain disease (Franklin's disease)
3. μ chain disease
4. δ chain disease

Cryoglobulinemia

It is a condition where the blood contains cryoglobulins; a type of Ig that becomes insoluble (precipitate) at low temperatures but redissolves again if the blood is heated.

- Cryoglobulins usually consist of IgM directed against the Fc region of IgG.
- Cryoglobulins have been associated with multiple myeloma and hepatitis C infection.

MONOCLONAL ANTIBODY

Monoclonal antibodies (mAb) are defined as the antibodies derived from a single clone of plasma cell; all having the same antigen specificity, i.e. produced against a single epitope of an antigen.

Polyclonal vs Monoclonal Nature of Antibody

When an antigen having multiple epitopes enters the body, each epitope may stimulate one clone of B cells producing one type of antibody. Hence the resultant antibody mixture present in serum is said to be **polyclonal**, i.e. contains mixture of antibodies derived from different clones of B cells.

However, when only one clone of B cell is stimulated by a single epitope of an antigen and then is allowed to proliferate and produce antibodies; such antibodies are referred to as **monoclonal** antibodies (mAb).

Production of mAb (Hybridoma Technique)

Monoclonal antibodies are produced by Hybridoma technique, developed by G Kohler and C Milstein (1975), for which they were awarded Nobel prize in 1984.

Principle

A clone of B cell stimulated against a single epitope of antigen is fused with an immortal cell, e.g. myeloma cell (capable of multiplying indefinitely) to produce a hybridoma cell. This hybridoma cell has two unique properties:

1. Produces monoclonal antibody of same antigen specificity (due to B cell component).
2. Multiplies indefinitely producing clone of identical cells (due to immortal myeloma cell component).

Procedure

The steps of hybridoma technique are as follows (Fig. 11.7):

- **Mouse splenic B cells:** The mouse is injected with an antigen containing the desired epitope. After an interval, the mouse splenic B cells are obtained which are activated against the epitope of the antigen injected.
- **Myeloma cells** are used as a source of immortal cells. They are cancerous plasma cells. They closely

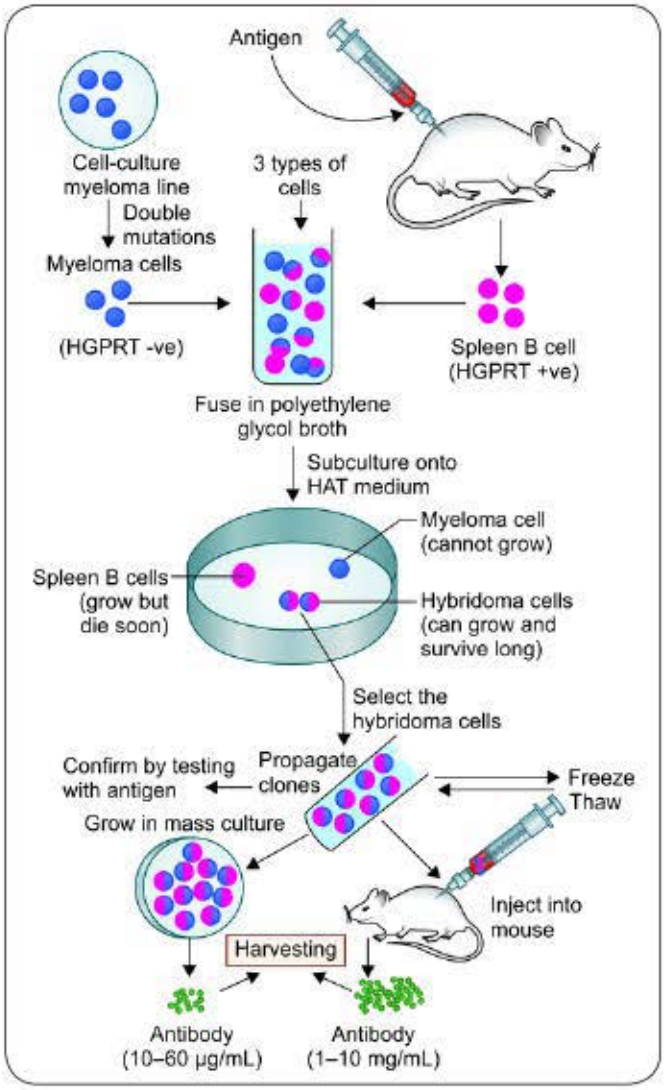

Fig. 11.7: Hybridoma technology

resemble mouse B cells; hence are compatible for fusion. However, myeloma cells also have the capacity to produce their own antibodies. Hence myeloma cells are genetically modified with two mutations (double mutated myeloma cells), so that they lose the ability to produce their own antibody but retain immortal property.

- **Fusion:** The mouse splenic B cells and mutated myeloma cells are fused in polyethylene glycol broth. In the reaction chamber, three types of cells will be generated:
  1. Unfused myeloma cells
  2. Unfused mouse splenic B cells
  3. Fused hybridoma cells
- **Purification** (by subculturing on HAT media): The next step is to remove the unwanted unfused cells and to propagate the clone of hybridoma cells. This is carried out by subculturing the cells in reaction chamber onto a special medium called HAT medium.
- **HAT medium:** It contains hypoxanthine, aminopterin and thymidine.
  - Purine synthesis in mammalian cell (e.g. splenic B cell) occurs by either *de novo* or salvage pathways.
  - Aminopterin blocks the *de novo* pathway so that the cell has to perform the salvage pathway to synthesize purines for its survival.
  - Salvage pathway requires two important enzymes-HGPRT (hypoxanthine guanine phosphoribosyl transferase) and thymidine kinase.
  - So any cell (e.g. myeloma cell) that lacks HGPRT cannot grow on HAT medium.
- **Fate of three type of cells on HAT media:**
  1. Unfused splenic B cells: They can grow, but do not survive long as they are not immortal.
  2. Unfused myeloma cells: They cannot grow as they lack HGPRT enzyme to perform the salvage pathway of purine synthesis.
  3. Hybridoma cells: They can grow and survive long.
- **Selection of individual hybridoma cells:** If the original antigen used has multiple epitopes, many B cells would fuse with myeloma cells to produce a mixture of hybridoma cells each having specificity for one epitope. The medium containing hybridoma cells is then diluted into multi-well plates to such an extent that each well contains only one cell. The hybridoma cells producing the desired monoclonal antibodies are selected by radioimmunoassay or ELISA techniques using the specific antigen fragments, and are selectively proliferated.
- **Maintenance of mAb:** The selected hybridoma cells can be maintained in two ways:
  1. Hybridoma cell is cultured to generate a clone of identical cells; producing pure form of monoclonal antibodies at a concentration of 10–60 µg/mL.
  2. Alternatively the desired hybridoma cell is injected into the peritoneal cavity of mouse where it can multiply and produce mAb in ascitic fluid at a concentration of 1–10 mg/mL. Such mAb obtained from mouse ascitic fluid and serum may not be in pure form, mixed with other antibodies; hence, it is purified by chromatography or by immunoprecipitation test.

Types of Monoclonal Antibodies

The above mentioned procedure would yield monoclonal antibodies whose 100% amino acids are mouse derived. The problem of mouse monoclonal antibody is that, the mouse proteins being foreign; can induce immune response in humans producing human anti-mouse antibodies (HAMA); that in turn eliminate the monoclonal antibodies faster from the body. Hence mouse derived monoclonal antibodies are not the best for human use. Since the discovery of hybridoma technique, various modifications have been attempted to produce monoclonal antibodies by recombining human and mouse proteins (Fig. 11.8).

- **Mouse mAb:** It contains 100% mouse derived proteins.
- **Chimeric mAb:** It is prepared by recombination of 34% mouse proteins (variable region) and 66% human proteins (constant region).
- **Humanized mAb:** Here, only the antigen binding site (i.e. CDR-complementarity determining region) is mouse derived (10%) and the remaining part of mAb is human derived.
- **Human mAb:** It contains 100% human derived aminoacids. It is the best accepted mAb in humans.

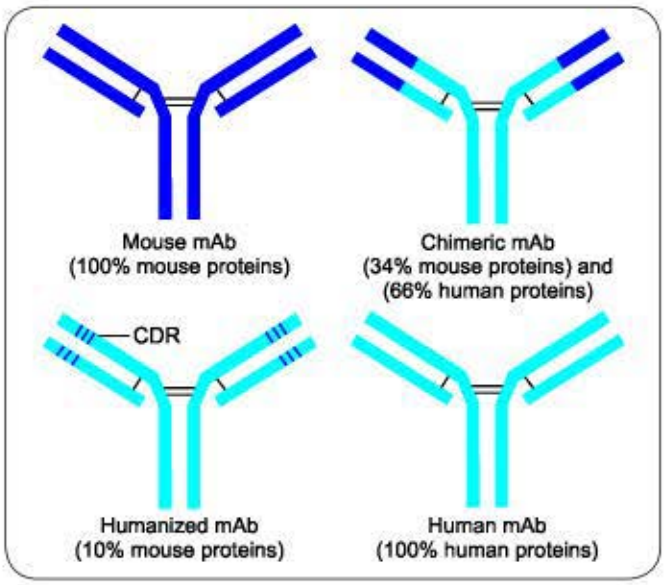

Fig. 11.8: Types of monoclonal antibodies

Applications of Monoclonal Antibodies

- **Isolation and purification:** Monoclonal antibodies can be used to purify individual molecule from a mixture even when they are present in low concentration, e.g. interferon and coagulation factor VIII.
- **Identification of cells and clones:** For example T_H and T_C cells are identified by using anti-CD4 and anti-CD8 mAb.
- **Diagnostic reagents:** The widest application of mAb is detection of antigen. The antigen detection kits employ various mAb tagged with detection molecules, such as fluorescent dye or enzyme to detect the specific antigens in the clinical specimen. Examples include:
  - Detection of infections, such as hepatitis B, serogrouping of streptococci, etc.
  - Pregnancy detection test—by using monoclonal antibody against human chorionic gonadotropin.
  - Blood grouping can be done by using anti-A and anti-B monoclonal antibodies.
  - Tumor detection and imaging: By using mAb specific for tumor antigens secreted by tumor cells (e.g. prostate specific antigen).
  - Tissue typing for transplantation can be done by using anti-HLA monoclonal antibodies.
- **Monitoring** proteins and drug levels in serum.
- **Passive immunity:** For post exposure prophylaxis against various infections, mAb targeting specific antigens of the infecting organism can be administered. Examples include—immunoglobulins against hepatitis B, rabies, and tetanus.
- **Therapeutic use:** Monoclonal antibodies are used in the treatment of various inflammatory and allergic diseases and cancers (Table 11.3). The mechanisms by which the mAb work as therapeutic agent are:
  - Suppress immune system
  - Kill or inhibit malignant cells
  - Inhibit angiogenesis
- **Used as immunotoxin:** mAb conjugated with bacterial/chemical toxins (e.g. diphtheria toxin) can be used to kill the target cells such as cancer cells. Here, mAb against surface receptors helps in binding to the target cells and the toxin helps in target cell killing.
- **Used as enzymes: Abzyme** is a monoclonal antibody with catalytic activity.

TABLE 11.3: Therapeutic uses of monoclonal antibodies

Monoclonal antibody	Targeted against	Used in treatment of
Suppress immune system		
Adalimumab and infliximab	TNF-α	Rheumatoid arthritis Crohn's disease
Omalizumab	IgE	Asthma
Daclizumab	IL-2 receptor	Rejection of kidney transplants
Muromonab	CD3	
Anticancer		
Trastuzumab	HER-2	Breast cancer
Rituximab	CD20	Lymphoma
Inhibit angiogenesis		
Bevacizumab	VEGF (vascular endothelial growth factor)	Colorectal cancers
Abciximab	Platelet receptor GpIIb/IIIa	Coronary artery disease

Note:
- Mouse mAb ends with suffix 'umab or onab'
- Chimeric mAb ends with suffix 'ximab'
- Humanized mAb ends with suffix 'zumab'
- Human mAb ends with suffix 'mumab'

GENETICS OF ANTIBODY PRODUCTION

The mechanism of organization of Ig gene is unique and different from the classical 'one gene-one polypeptide' genetic model. In contrast, Ig polypeptide chains are coded by more than one gene. This concept was first introduced by Dreyer and Bennett. Later it was proved by Tonegawa and Hozumi (1975) for which they were awarded Nobel prize (1987).

Multigene Organization of Immunoglobulin

There are three basic principles of this model which are summarized below:

1. **Ig molecule is not coded by a single gene:** The two H and two L chains of an Ig molecule are coded by separate gene segments which are then joined later.
   - Heavy chain is coded by four gene segments: V (variable), D (diversity) and J (joining) and C (constant) gene segments. C_H gene region further consists of nine segments. The V_H, D_H and J_H gene segments collectively code for the variable region and the C_H gene segment codes for the constant region of H chain.
   - Light chains are coded by three genes V, J and C gene segments. The D gene segment is absent. The V and J segments together code for variable region and C gene segment codes for the constant region of L chain. Kappa and lambda L chains are coded by two different sets of V, J and C genes.
2. **Ig genes are encoded in different chromosomes:**
   - H chain gene family is located on chromosome number 14.
   - Kappa light chain gene family is located on chromosome number 2.
   - Lambda light chain gene family is located on chromosome number 22.

3. **Multiple genes:** There are multiple genes existing for each genetic segment of Ig chain (described later under antibody diversity).

Rearrangement of Immunoglobulin Genes

The complete Ig molecule is formed by recombination between various gene segments. Gene rearrangement occurs at DNA and RNA levels.

Rearrangement at DNA Level

This involves rearrangement and splicing between the DNA segments of variable region of both H and L chains.

- H chain gene region undergoes rearrangement first followed by L chain gene region.
- In H chain, V-D joining occurs first followed by VD-J joining whereas in L chain, only V -J joining takes place. Recombination of gene segments occurs at the time of joining which is mediated by special **recombinase** enzymes, encoded by *RAG* (recombination activation genes).
- The C gene segments of both H and L chains are not joined at DNA level; but remain separate.

Rearrangement at RNA Level

The V, D, J and C gene segments are transcribed to generate primary RNA transcript. Then the C region RNA transcripts combine with variable region RNA transcripts to generate complete H and L chains.

- The whole C_H region is not transcribed simultaneously. First, the Cμ and Cδ genes are transcribed and combined with corresponding variable region RNA transcript to produce complete IgM and IgD respectively.
- Based on class switch over of B cell, other C_H region genes are transcribed, to produce Ig of other classes (described later).
- **Differential Ig RNA processing:** It is an important event which occurs at post translational level which is responsible for:
  - Directing the synthesis of immunoglobulin as membrane bound Ig or secretory Ig.
  - Simultaneous expression of membrane Ig (IgM and IgD) on surface of mature B cells.

Antibody Diversity

Human immune system is capable of producing vast number of antibodies (10^8 or even more) corresponding to various epitopes of different antigens. With the understanding of genetics of Ig genes and their rearrangement; many possible mechanisms have been put forward to explain this diversity.

Mechanism of Antibody Diversity

- **Multiple genes for each segment coding for Ig chain:** Large numbers of different genes are known to exist for each genetic segment of Ig gene (Table 11.4). For example, there are 51 V_H genes known to exist in nature and every H chain would have one out of 51 V_H genes
- **Many possible combinations of joining of variable region gene segments (Table 11.5):** As at each gene segment multiple genes exist, there are several combinations possible by which joining of V/D/J genes can occur.
- **Junctional flexibility:** It is postulated that V-DJ, D-J and V-J joining can take place at any level of several nucleotides present at the ends of V, D, J segments.
- **Junctional diversity:** The V/D/J joining is a highly inaccurate process that results in the addition or subtraction of variable number of nucleotides and, thus, generates junctional diversity.
- **Somatic hypermutation:** After formation of complete Ig molecule, still changes can occur in the nucleotide sequence of variable region. This usually occurs following antigenic stimulus to B cells in lymphoid follicles. The V region genes undergo point mutations (resulting from nucleotide substitutions) at a higher frequency (10^{-3} /bp/generation) than the normal (10^{-8} /bp/generation), hence named as hypermutation. This helps in affinity maturation of B cells.

TABLE 11.4: Multiple genes coding H and L chains of Ig

Gene segment	Number of genes		
	H chain	κ L chain	λ L chain
V	51	40	30
D	27	0	0
J	6	5	4
C	9	1	4

TABLE 11.5: Possible number of combinations of variable genes joining

Type of joining	Possible combinations
V-D-J combinations in heavy chain	51 V_H X 27 D_H X 6 J_H genes = 8262
V-J combinations in κ chain	40Vκ X 5Jκ genes = 200
V-J combinations in λ chain	30Vλ X 4Jλ genes = 120
Combinations of H and L chains	8262 X 200 X 120 = 2.64 X 10^6

Class Switch Over

Once B cell is stimulated by an antigen, heavy chain gene undergoes rearrangement where VDJ segment combines with one of the C_H gene segments; first with Cμ (forming IgM) followed by the others. This process is called class switching or isotype switching.

The classes and subclasses of Ig vary in their constant region of H chain. The C region of heavy chain contain nine segments each coding for a specific class or subclass of H chain. They are arranged in a specific sequence after the J chain. The sequence from the 5′ end is as follows—5′→ V → D → J → Cμ → Cδ → Cγ3 → Cγ1 → Cα1 → Cγ2 → Cγ4 → Cε → Cα2 → 3′

- Each C_H region genes except Cδ, contains a highly conserved DNA flanking sequence containing tandem repeats called as **switching site**.
- It is proposed that there are class specific and subclass specific recombinase which are capable of binding to these switching sites, following which the corresponding C_H region gene and VDJ segment are joined together.
- The class switch over helps the B cells to produce Ig of different class, retaining the same antigen specificity.
- Class switch over is not a random phenomenon, but regulated by specific cytokines secreted by helper T cells (Described in detail in Chapter 15).

EXPECTED QUESTIONS

I. Essay:

1. Define antibody. Describe in detail about the structure and functions of various types of antibodies?

II. Write short notes on:

1. Idiotypes
2. Monoclonal antibodies
3. Abnormal immunoglobulins

III. Multiple Choice Questions (MCQs):

1. Which antibody crosses placenta?
a. IgA b. IgG
c. IgE d. IgM

2. Which is an example of surface Ig?
a. IgA b. IgG
c. IgE d. IgM

3. Ig heavy chain is encoded in which chromosome?
a. 2 b. 14
c. 22 d. 23

4. What is the total valancies of IgM?
a. 10 b. 5
c. 2 d. 1

Answers
1. b **2.** d **3.** b **4.** a

CHAPTER 12

Antigen–Antibody Reaction

Chapter Preview

- General properties of antigen–antibody reactions
- Types of antigen–antibody reactions
- Conventional techniques
  - Precipitation reaction
  - Agglutination reaction
  - Complement fixation test
  - Neutralization test
- Newer techniques
  - Enzyme-linked immunosorbent assay (ELISA)
  - Immunofluorescence assay (IFA)
  - Radioimmunoassay (RIA)
  - Chemiluminescence-linked immunoassay (CLIA)
  - Rapid tests
  - Western blot
  - Immunoassays using electron microscope

The antigen antibody reaction is a bimolecular association where the antigen and antibody combine with each other specifically and in an observable manner similar to an enzyme-substrate interaction, the only difference is, it does not lead to an irreversible alteration in either antibody or in antigen.

GENERAL PROPERTIES OF ANTIGEN–ANTIBODY REACTIONS

Antigen (Ag)–antibody (Ab) reactions are characterized by the following general properties:

Specific

Ag-Ab reaction involves specific interaction of epitope of an antigen with the corresponding paratope of its homologous antibody. Exception is the cross reactions which may occur due to sharing of epitopes among different antigens. In such case, antibody against one antigen can cross react with a similar epitope of a different antigen.

Noncovalent Interactions

The union of antigen and antibody requires formation of large number of non-covalent interactions between them such as:

- Hydrogen bonds
- Electrostatic interactions
- Hydrophobic interactions
- Van der Waals forces

Strength

The strength or the firmness of the association is influenced by the affinity and avidity of the antigen–antibody interaction.

Affinity

It refers to the sum total of noncovalent interactions between a single epitope of an antigen with its corresponding paratope present on antibody. Affinity can be measured by two methods: (1) by equilibrium dialysis and (2) by surface plasmon resonance method.

Avidity

It is a term used to describe the affinities of all the binding sites when multivalent antibody reacts with a complex antigen carrying multiple epitopes.

- The total strength (i.e. avidity) would be much higher than the individual affinity at each binding site, but lower than the sum of all affinities. This difference is primarily due to geometry of Ag-Ab binding.
- The geometry of the multivalent antibody gets stretched when it reacts with a complex antigen, as it has to reach and accommodate all the epitopes, thus resulting in less optimal binding interactions.
- Avidity is a better indicator of strength of an antigen antibody reaction. Avidity of an antibody can compensate for its low affinity. For example, IgM has a low affinity than IgG but it is multivalent (10 valencies), therefore has a much higher avidity. Hence, it can bind to an antigen more effectively than IgM.

Diagnostic Use

Because Ag-Ab reactions are specific and observable, they are extensively used in the laboratories for the diagnosis of infectious diseases. The diagnostic tests based on antigen-Ag-Ab reactions are called as immunoassays. Most

immunoassays are also called serological tests as they are performed in serum samples. However, other samples can also be used such as urine, CSF, etc. Immunoassays can be broadly categorized into two types:

1. **Antigen detection assays:** Detect antigens in patient's sample by employing specific antibody.
2. **Antibody detection assays:** Detect antibodies in patient's sample by employing specific antigen.

Qualitative vs Quantitative Immunoassays

Immunoassays can be performed by both qualitative and quantitative methods.

Qualitative Assays

Here, the undiluted specimen containing the antibody is directly mixed with the suspension of antigen or vice versa. The result is read as 'positive' or 'negative' based on presence or absence of antigen or antibody in the clinical specimen. The exact amount of antigen or antibody present in the specimen will not be known.

Quantitative Assays

When the qualitative test turns positive, the exact amount of antibody in serum can be known by serial dilution of the patient's serum and mixing each dilution of the serum with a known quantity of antigen. The measurement of antibody is expressed in terms of titer.

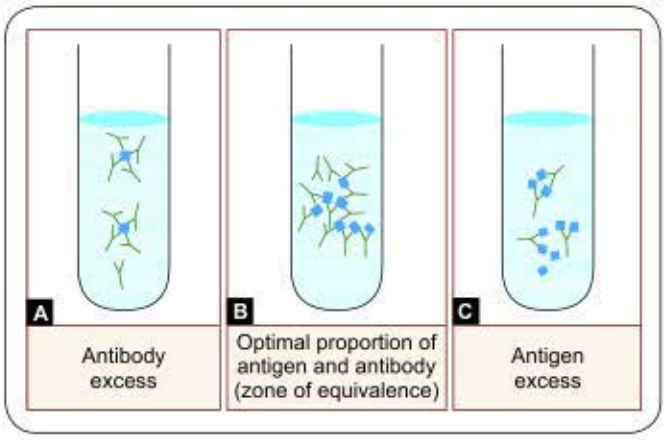
- The **antibody titer** of a serum is the highest dilution that shows an observable reaction with the antigen.
- Antigen titer can also be measured in the sera in similar fashion by testing the series of diluted sera against known quantity of antibody.

The problem with qualitative test is that if the number of antigen or antibody molecules in the reaction are disproportionate to each other and if either antigen or antibody are present in higher quantity, then the antigen antibody reaction does not take place and often the result turns negative (false-negative). To rule out a false negative result, it is ideal to test the series of diluted sera (quantitative test), instead of just testing the one specimen of undiluted serum. Quantitative tests are more reliable as they can differentiate between true negative and false-negative results. This can be explained by Marrack's Lattice hypothesis.

Marrack's Lattice Hypothesis

When the sera containing antibody is serially diluted (in normal saline), gradually the antibody level decreases. When a fixed quantity of antigen is added to such a set of test tubes containing serially diluted sera, then it is observed that the Ag-Ab reaction occurs at its best only in the middle test tubes where the amount of antigen and antibody are equivalent to

Contd...



Figs 12.1A to C: **A.** Prozone; **B.** Zone of equivalence; **C.** Post zone

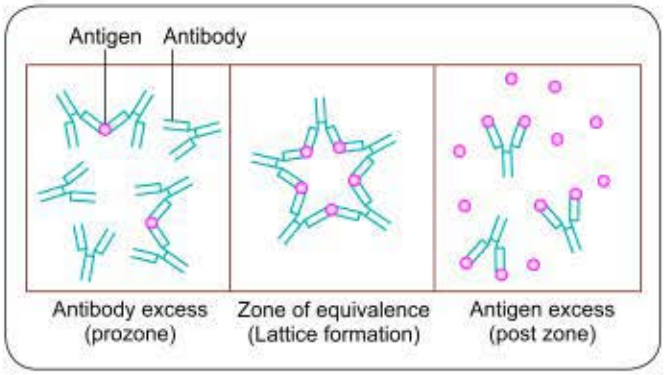


Fig.12.2: Lattice hypothesis

Contd...

each other (*zone of equivalence*). The Ag-Ab reaction is weak or fails to occur when the number of antigen and antibodies are not proportionate to each other (Figs 12.1 and 12.2).

- In the earlier test tubes, *antibodies are excess*, hence the Ag-Ab reaction does not occur: This is called as **prozone phenomenon**.
- In the later test tubes, *antigen is excess*, hence the Ag-Ab reaction fails to occur: This is called as **post zone phenomenon**.

Marrack (1934) proposed the **lattice hypothesis** to explain this mechanism. According to this concept the multivalent antigens combine with bivalent antibodies in varying proportions, depending on the antigen antibody ratio in the reacting mixture (Fig. 12.2).

- Ag-Ab reaction optimally occurs when a large lattice is formed consisting of alternating antigen and antibody molecules. This is possible only in the zone of equivalence.
- In the zones of antibody or antigen excess (prozone/post zone), the lattice does not enlarge, due to inhibition of lattice formation by the excess antibody or antigen respectively.

Contd...

Contd...

Lattice hypothesis was described first for precipitation reaction, but it also holds true for agglutination and other techniques of Ag-Ab reactions.
The prozone phenomenon is of great importance in clinical serology, as sera rich in high titer of antibody may sometimes give a false-negative result, unless serial dilutions of sera are tested.

Evaluation of Immunoassays

Evaluation of the performance of any diagnostic test including immunoassays can be done by calculating various statistical measures. Among all, sensitivity and specificity are the two most important statistical parameters.

Sensitivity is defined as ability of a test to identify correctly all those who have the disease, i.e. true-positives.

$$\text{Sensitivity is calculated as} = \frac{\text{True positives}}{\text{True positives} + \text{False negatives}}$$

Specificity is defined as ability of a test to identify correctly all those who do not have disease, i.e. true negatives.

$$\text{Specificity is calculated as} = \frac{\text{True negatives}}{\text{True negatives} + \text{False positives}}$$

TYPES OF ANTIGEN–ANTIBODY REACTIONS

The antigen–antibody reactions used in diagnostic laboratories are based on various techniques which are broadly classified as conventional or old techniques and newer techniques (Table 12.1).

TABLE 12.1: Types of antigen–antibody reactions

Conventional techniques
▪ Precipitation reaction
▪ Agglutination reaction
▪ Complement fixation test
▪ Neutralization test
Newer techniques
▪ Enzyme linked immunosorbent assay (ELISA)
▪ Immunofluorescence assay (IFA)
▪ Radioimmunoassay (RIA)
▪ Chemiluminescence-linked immunoassay (CLIA)
▪ Immunohistochemistry
▪ Rapid tests • Lateral flow assay (Immunochromatographic test) • Flow through assay
▪ Western blot
▪ Immunoassays using electron microscope

CONVENTIONAL IMMUNOASSAYS

PRECIPITATION REACTION

Definition

When a **soluble antigen** reacts with its antibody in the presence of optimal temperature, pH and electrolytes (NaCl), it leads to formation of the antigen–antibody complex in the form of:

- Insoluble precipitate band when gel containing medium is used or
- Insoluble floccules or precipitate ring when liquid medium is used.

Precipitation in Liquid Medium

- **Ring test:** In a narrow tube (e.g. capillary tube), antigen solution is layered over an antiserum; a precipitate ring appears at the junction of two liquids. Examples of ring tests are streptococcal grouping by Lancefield technique, and Ascoli's thermoprecipitin test done for anthrax.
- **Flocculation test:** When a drop of antigen is mixed with a drop of patient's serum, then the precipitate formed remains suspended as floccules. This test can be done on a slide or in a tube.
  - Examples of slide flocculation test: VDRL and RPR tests used for diagnosis of syphilis.
  - Examples of tube flocculation test: Kahn test used previously for syphilis.

Precipitation in Gel (Immunodiffusion)

Incorporation of 1% soft agarose gel in precipitation reaction has many advantages over liquid medium:

- It results in formation of clearly visible **bands** instead of floccules, which can be preserved for longer time.
- It can differentiate individual antigens from a mixture, as each antigen forms a separate band after reacting with specific antibody.

Immunodiffusion tests are based on two principles—

1. Whether only Ag diffuses (single diffusion) or both Ag and Ab diffuse (double diffusion).
2. Whether Ag or Ab diffuses in *one dimension* (i.e. vertical diffusion when test is done on a tube layered with gel) or **two dimensions** (i.e. diffusion in both X and Y axis, which occurs when the test is done on a slide or a petri dish layered with gel).

There are four types of immunodiffusions in gel:

1. **Single diffusion in one dimension (Oudin procedure):** When antigen solution is poured over a layer of gel containing antibody, only the antigen diffuses in one direction towards antibody to form a band (Fig. 12.3).

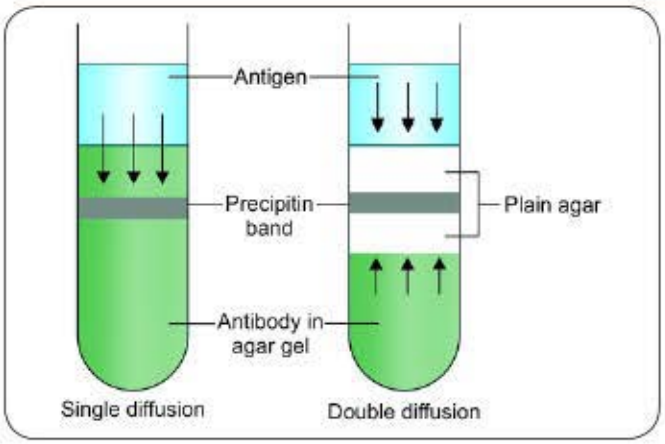

Fig. 12.3: Single and double diffusion in one dimension

2. **Double diffusions in one dimension (Oakley-Fulthorpe procedure):** In the above test, if a column of plain agar is placed between the antigen layer and the layer of gel incorporated with antibody; then both antigen and antibody move towards each other in opposite directions and the precipitate band is formed at the line they meet in the plain agar (Fig. 12.3).
3. **Single diffusion in two dimensions (Radial immunodiffusion):** Gel incorporated with antibody is placed on a slide and several wells are cut. When drops of antigen are placed in the wells, they diffuse radially in all directions to meet with antibody and ring-shaped bands are formed around the well (Fig. 12.4). The diameter of the ring is directly proportional to the concentration of the antigen in the well.
4. **Double diffusions in two dimensions (Ouchterlony procedure):** On a slide poured with agar gel, antibody is placed in a central well and the surrounding wells are filled with different antigens. Both antigen and antibody moves towards each other in all the directions and form bands (Fig. 12.5).

   The adjacent precipitate bands interact in 3 ways:
   - They may **fuse** with each other (indicates both antigens are identical).
   - They may **cross** one another (indicates antigens are unrelated).
   - They may cause **spur** formation (indicates cross reaction or partial identity) (Fig. 12.5).

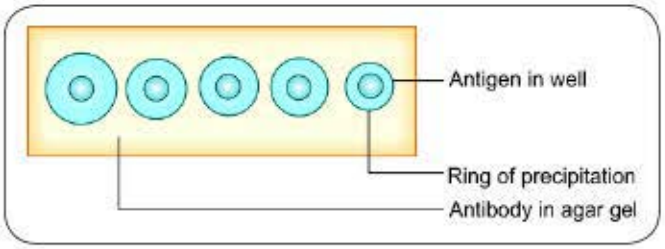

Fig. 12.4: Single diffusion in two dimensions

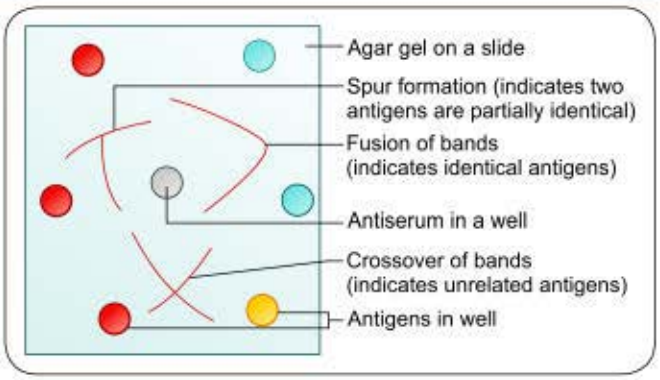


Agar gel on a slide
Spur formation (indicates two antigens are partially identical)
Fusion of bands (indicates identical antigens)
Antiserum in a well
Crossover of bands (indicates unrelated antigens)
Antigens in well

Fig. 12.5: Double diffusion in two dimensions

Examples of double diffusions in two dimensions include-Elek's test for detecting toxin of *Corynebacterium diphtheriae* and Eiken test to detect toxin of *Escherichia coli*.

Precipitation in Gel in Presence of Electric Current

The problem with immunodiffusion in gel is that, antigen and antibody move very slowly in a gel, hence it takes several days to finish the procedure. Their movement can be made faster if immunodiffusion is carried out in presence of electric current.

Electroimmunodiffusion (EID)

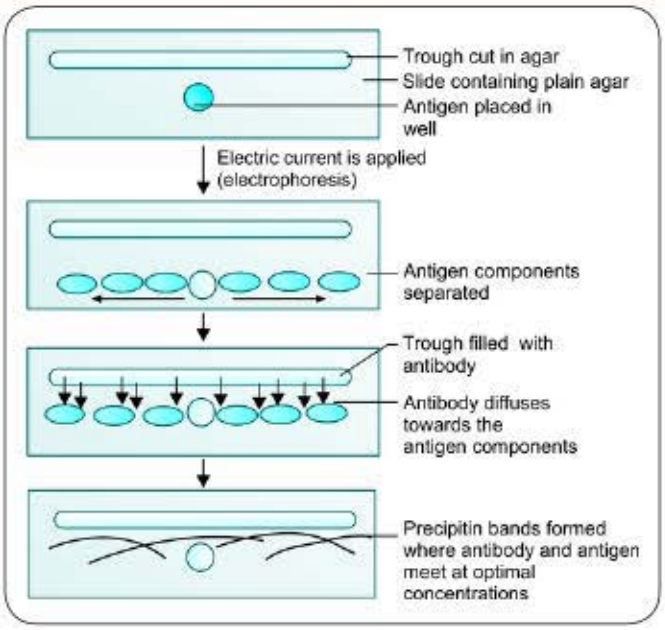
When electric current is applied to a slide layered with gel, the serum proteins(antigen mixture) placed in a well are separated into individual antigen components. Antiserum present in a trough moves towards the antigen components resulting in formation of separate precipitin lines in 18–24 hrs, each indicating reaction between individual proteins with its antibody (Fig. 12.6). This test helps in identification and approximate quantitation of various proteins present in the serum.

Countercurrent Immunoelectrophoresis (CIEP)

This test is even faster (takes 30 minutes) and more sensitive than EID because it involves simultaneous electrophoresis of the antigen and the antibody in gel in opposite directions resulting in band formation (Fig. 12.7). This test was very popular in the past, for detecting various antigens such as alpha fetoprotein in serum and capsular antigens of *Cryptococcus* and meningococcus in the cerebrospinal fluid.

Rocket Electrophoresis

This is an one-dimensional single electroimmunodiffusion test, mainly done in the past for quantitative estimation of antigens (Fig. 12.8).



Trough cut in agar
Slide containing plain agar
Antigen placed in well
Electric current is applied (electrophoresis)
Antigen components separated
Trough filled with antibody
Antibody diffuses towards the antigen components
Precipitin bands formed where antibody and antigen meet at optimal concentrations

Fig. 12.6: Immunoelectrophoresis

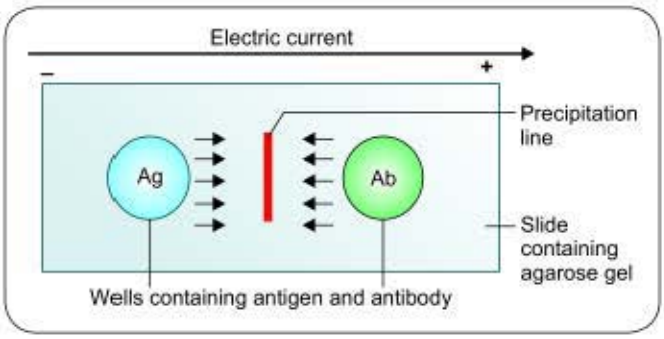


Fig. 12.7: Countercurrent immunoelectrophoresis

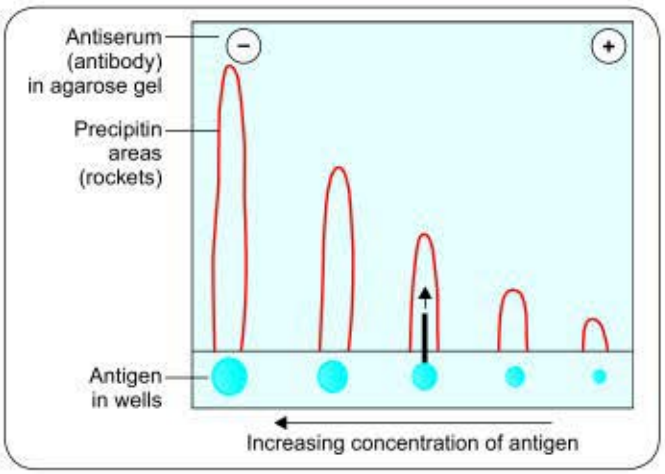

Fig. 12.8: Rocket electrophoresis

Once upon a time precipitation reactions were one of the widely used serological tests; however with the advent of simple and rapid newer techniques their application is greatly reduced, except the VDRL test which is still used for the diagnosis of syphilis.

AGGLUTINATION REACTION

Definition

When a **particulate** or **insoluble** antigen is mixed with its antibody in the presence of electrolytes at a suitable temperature and pH, the particles are clumped or agglutinated.

- **Advantage:** Agglutination is more sensitive than precipitation test and the clumps are better visualized and interpreted than bands or floccules. Hence, agglutination tests are widely used even in today's modern era of diagnosis.
- **Applications:** Agglutination reactions are classified as direct, indirect (passive) and reverse passive agglutination reactions. All these agglutination tests are performed either on a slide, or in tube or in card or some time in microtiter plates.

Direct Agglutination Test

Here, the antigen directly agglutinates with the antibody.

Slide Agglutination

It is usually performed to confirm the identification and serotyping of bacterial colonies grown in culture. It is also the method used for blood grouping and cross matching.

Bacterial colony is mixed with a drop of saline on a slide to form a uniform smooth milky white suspension

↓

To this, a drop of the antiserum (serum containing appropriate antibody) is added and the slide is shaken thoroughly (manually or by rotator) for few seconds

↓

A positive result is indicated by visible clumping with clearing of the suspension (Fig. 12.9)

or

If the milky white suspension remains unchanged, indicates a negative result (Fig. 12.9).

Tube Agglutination

This is a quantitative test done for estimating antibody in serum. The **antibody titer** can be estimated as the highest dilution of the serum which produces a visible agglutination.

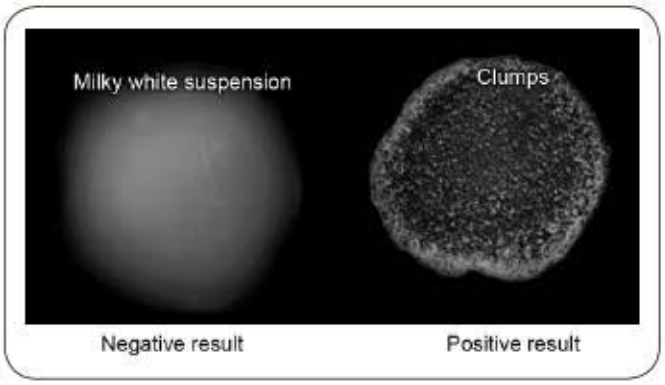

Fig. 12.9: Slide agglutination test

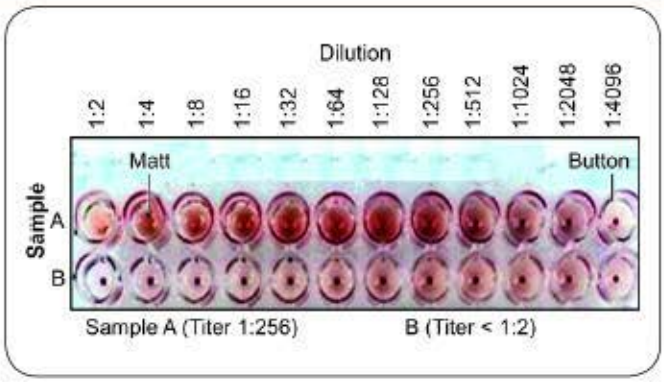

Fig. 12.10: Indirect hemagglutination test

A fixed volume of a particulate antigen suspension is added to an equal volume of serial dilutions of a serum sample (containing appropriate antibody) in test tubes

↓

Positive test indicates agglutination (clump formation at the bottom of the tube with clearing of the supernatant)

or

Negative test indicates agglutination has not occurred (Ag suspension forms button at the bottom of the tube)

Tube agglutination is routinely used for the serological diagnosis of various diseases, such as:

- Typhoid fever (Widal test): It detects antibodies against both H (flagellar) and O (somatic) antigens of *Salmonella* Typhi.
  - H antigen–antibody clumps appear as loose fluffy clumps
  - O antigen–antibody clumps appear as chalky white granular dense deposits
- Acute brucellosis (Standard agglutination test)
- Coombs antiglobulin test (see the proceeding text)
- Heterophile agglutination tests:
  - Typhus fever (Weil Felix reaction)
  - Infectious mononucleosis (Paul Bunnell test)
  - *Mycoplasma* pneumonia (Cold agglutination test).

Microscopic Agglutination

Here, the agglutination test is performed on a microtiter plate and the result is read under a microscope. The classical example is microscopic agglutination test (MAT) is done for leptospirosis.

Indirect or Passive Agglutination Test (for Antibody Detection)

As agglutination test is more sensitive and better interpreted than precipitation test, hence attempt has been made to convert a precipitation reaction into an agglutination reaction. This is possible by coating the soluble antigen on the surface of a carrier molecule (e.g. RBC, latex or bentonite), so that the antibody binds to the coated antigen and agglutination takes place on the surface of the carrier molecule.

Indirect Hemagglutination Test (IHA)

It is a passive agglutination test where RBCs are used as carrier molecules. It results in formation of matt or button which indicate presence or absence of agglutination respectively (Fig. 12.10). The test is performed on a microtiter plate. IHA was used widely in the past, but is less popular at present.

Latex Agglutination Test (LAT) for Antibody Detection

Here, polystyrene latex particles (0.8–1 μm in diameter) are used as carrier molecules which are capable of adsorbing several types of antigens. For better interpretation of result, the test is performed on a black color card.

- Drop of patient's serum (containing antibody) is added to a drop of latex solution coated with the antigen and the card is rotated for uniform mixing.
- Positive result is indicated by formation of visible clumps (Fig. 12.11). LAT is one of the most widely used tests at present as it is very simple and rapid.
- It is used for detection of ASO (antistreptolysin O antibody).

Reverse Passive Agglutination Test (for Antigen Detection)

In this test, the antibody is coated on a carrier molecule which detects antigen in the patient's serum.

- **Reverse passive hemagglutination assay (RPHA):** Here, the RBCs are used as carrier molecules. RPHA was used in the past for detection of hepatitis B surface antigen (HBsAg).
- **Latex agglutination test for antigen detection:** It is used widely for detection of CRP (C reactive protein),

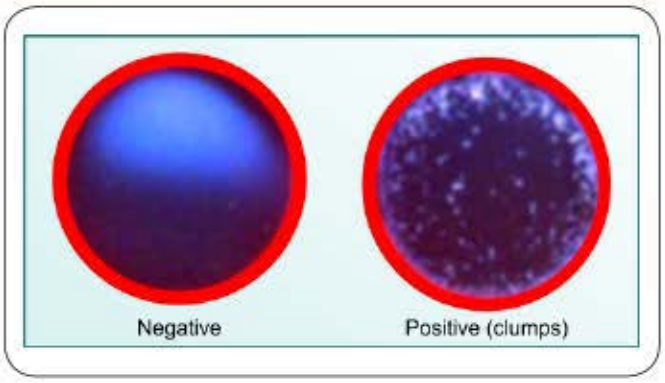

Fig. 12.11: Passive (latex) agglutination test

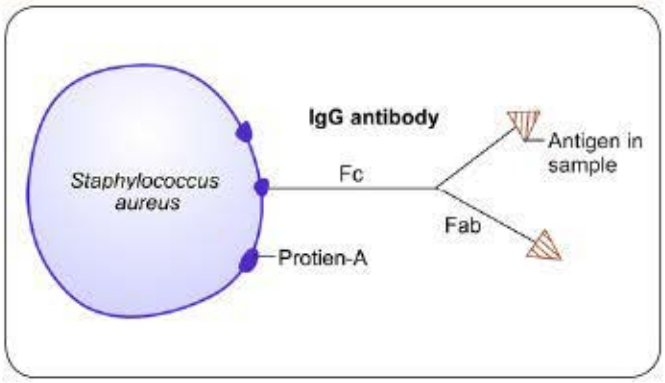

Fig. 12.12: Coagglutination test

RA (rheumatoid arthritis factor), capsular antigen detection in CSF (for pneumococcus, meningococcus and *Cryptococcus*) and streptococcal grouping.

- **Coagglutination test:** It is another example of passive agglutination test, where *Staphylococcus aureus* acts as carrier molecule.
  - Some strains of *S. aureus* (Cowan 1 strain) possess *protein A* on the surface, which has a property of binding to Fc portion of any IgG molecule (except IgG3) making the Fab portion free, which can agglutinate with the corresponding antigen present in the clinical sample (Fig. 12.12).
  - Coagglutination was a popular antigen detection test in the past (e.g. *Salmonella* antigen detection from blood and urine), but now it is almost replaced by latex agglutination test.

Hemagglutination Test

It refers to the agglutination tests that use RBCs as source of antigen. Various types of hemagglutination tests include:

Direct Hemagglutination Test

Serum antibodies directly agglutinate with surface antigens of RBCs to produce a matt. Examples include:

- **Paul Bunnell test:** It employs sheep RBCs as antigens to detect Epstein Barr virus antibodies in serum. The test is performed in tubes.
- **Cold agglutination test:** It uses human RBCs as antigens to detect *Mycoplasma* antibodies in serum. Test is performed in tubes.
- **Blood grouping** (ABO and Rh grouping)
- **Coombs test** or **Antiglobulin test:** It is performed to diagnose Rh incompatibility by detecting Rh antibody from mother's and baby's serum.
  - Rh incompatibility is a condition when an Rh negative mother (Rh Ag -ve and Rh Ab -ve) delivers a Rh positive baby (Rh Ag +ve and Rh Ab -ve). During birth, some Rh Ag +ve RBCs may pass from fetus to the maternal circulation and may induce Rh Ab formation in mother and affect future Rh positive pregnancies.
  - **Rh antibodies** are **incomplete** or **blocking** antibodies of IgG type. They can cross placenta and bind to Rh Ag on fetal RBCs. However, that does not result in agglutination; instead, they block the sites on fetal RBCs.
  - Such reaction can be visualized by adding **Coombs reagent** (antiglobulin or antibody to human IgG) which can bind to Fc portion of Rh Ab bound on RBCs, resulting in visible agglutination.

Coombs test may be of two types (Fig. 12.13):

1. **Direct Coombs test:** It detects Rh antibodies bound to RBCs *in vivo*, present in fetus/baby's serum by directly adding Coombs reagent.

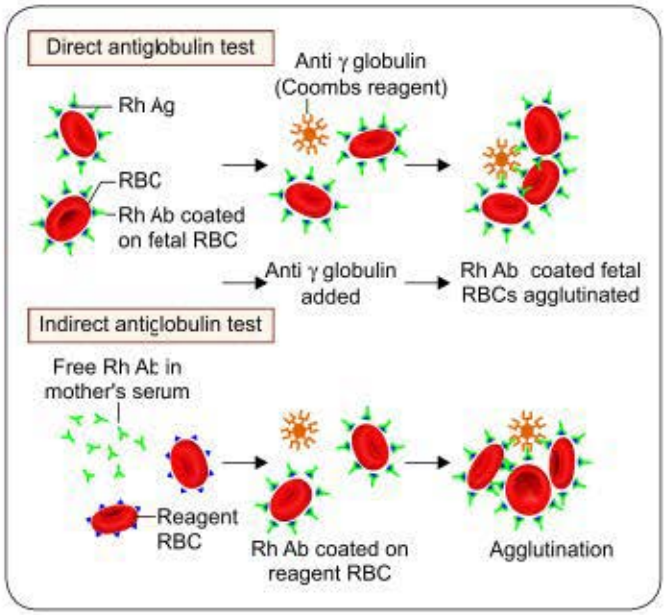

Fig. 12.13: Coombs or antiglobulin test

2. **Indirect Coombs test:** It detects free Rh antibodies present in maternal serum after the first delivery of an Rh +ve fetus/baby. The free Rh Abs are mixed with the reagent containing Rh +ve RBCs (*in vitro*), following which the Coombs reagent is added.

Indirect Hemagglutination Test

It is already described under indirect agglutination test.

Viral Hemagglutination Test

In strict sense, it is not an antigen antibody reaction. The hemagglutinin antigens (HA) present on surface of some viruses (hemagglutinating viruses, e.g. influenza virus) can agglutinate with the receptors present on the surface of RBCs.

Technical Issues in Agglutination Reactions

Two main problems pertaining to agglutination are prozone phenomenon and blocking antibody; both can cause false-negative agglutination test.

1. **Prozone phenomenon:** Serum containing excess antibodies may fail to agglutinate with its antigen. This can be obviated by serial dilution of the serum and testing the antigen with each dilution of the serum sample.
2. **Blocking antibodies** They are incomplete IgG antibodies. When they bind to antigens, they themselves cannot produce a visible agglutination; however, they can block the sites on antigens, thus prevent binding of any other antibodies to the antigens. Such blocking antibodies may be detected by performing the test in hypertonic (4%) saline or more reliably by adding antiglobulin or Coombs reagent.

COMPLEMENT FIXATION TEST

Complement fixation test (CFT) detects the antibodies in patient's serum that are capable of fixing with complements. It was once very popular, now is almost obsolete.

Principle

It is a two-step reaction. Before starting the test, serum inactivation (56°C for 30 min) is done to remove the non-specific inhibitors of complements present in serum.

In the First Step

[Antigen (soluble or particulate) + test serum + Guinea pig complement] → all added together.

- If the test serum is positive for antibody → Ag-Ab complex is formed. Complement gets fixed to the complex, so there will be no free complements in the serum.
- If the test serum is negative for antibody → there is no Ag-Ab complex. Complements are not fixed, hence remain free in the serum.

In the Second Step

A hemolysis indicator system is added. It consists of sheep RBCs coated with its antibodies called **amboceptor**s (prepared by injecting sheep RBCs into rabbit).

- If the test serum is positive for antibody → There is no free complement in serum to bind to amboceptors → There is no hemolysis.
- If the test serum is negative for antibody → The free complements are fixed to amboceptors bound on sheep RBCs → Results in hemolysis.

Applications

- **Wasserman test** was the most popular CFT, used for the diagnosis of syphilis.
- In addition, CFT was also widely used for detection of complement fixing antibodies in *Rickettsia, Chlamydia, Brucella, Mycoplasma* infections and some viral infections, such as arboviruses, rabies, etc.
- **Indirect complement fixation test** was used in the past to detect certain avian (e.g. duck, parrot) and mammalian (e.g. horse, cat) serum antibodies which cannot fix guinea pig complement.

Other Diagnostic Applications of Complements

Complements are also used for various serological tests other than CFT, such as:

- *Treponema pallidum* immobilization test (for detecting antibodies to *T. pallidum*).
- Sabin-feldman dye test for detecting *Toxoplasma* antibodies.
- Vibriocidal antibody test: When *V. cholerae* is mixed with serum containing specific antibody in presence of complement, the bacterium is killed and lysed.

NEUTRALIZATION TEST

Neutralization tests are also less commonly used in modern days. Various examples are as follows:

- **Viral neutralization test:** It detects the presence of neutralizing antibody in patient's serum. When the serum is mixed with a live viral suspension and poured onto a cell line, specific serum antibody neutralizes the surface antigen, making the virus unable to infect a cell line. Viral neutralization is of two types:
  1. **Reversible neutralization:** If virus-serum mixture is diluted, within 30 minutes the process of neutralization gets reversed and virus regains the ability to infect the cell line.
  2. **Stable neutralization:** Over the time, the process of neutralization becomes stable and does not get reversed even on dilution.
- **Plaque inhibition test:** This is a neutralization test done for bacteriophages.
- **Toxin-antitoxin neutralization test:** Examples include

- **Schick test:** It is a diphtheria toxin–antitoxin neutralization test. It was used in the past to know the susceptibility of individuals to *Corynebacterium diphtheriae*.
- **Nagler's reaction:** Opalescence on egg yolk agar produced by α-toxin of *Clostridium perfringens* is inhibited when anti-α-toxin is added to the medium, which neutralizes the α toxin.
- **ASO test:** Antistreptolysin O antibody was detected before by neutralization method; however, it is now replaced by latex agglutination.

- **Hemagglutination inhibition (HAI) test:** It is a popular test, used for detection of antibodies in patient's sera which agglutinate with the hemagglutinin antigens present on the surfaces of some viruses. This test is useful for the diagnosis of various viral diseases, e.g. influenza. The test principle is described in Chapter 44.

NEWER TECHNIQUES

The newer techniques use a detector molecule to label antibody or antigen which in turn detects the corresponding antigen or the antibody in the sample by producing a visible effect. Most of the newer techniques use the same principle, but they differ from each other by the type of labeled molecule used and the type of visible effect produced (Table 12.2).

ENZYME IMMUNOASSAY

Enzyme immunoassay (EIA) is a term used to describe all the tests that detect either antigen or antibodies or haptens in the specimen, by using enzyme–substrate system for detection. They can be classified into homogenous or heterogeneous EIA.

Homogeneous EIA

It is performed for detection of haptens such as drugs (e.g. opiates, cocaine), but not for microbial antigens and antibodies.

- **One step**: The test can be completed in one step, with all the reagents added simultaneously. There is no need to separate the bound and free fractions of haptens, hence there is no washing step needed.
- Example of homogeneous assay is enzyme multiplied immunoassay techniques (EMIT).

Heterogeneous Assays

They are used for detection of antigens and antibodies.

- **Multiple steps:** It requires the separation of the free and bound fractions which is carried out by absorption of the test Ag or Ab on to the solid surface followed by washing. It involves multiple steps with different reagents being added at every step.
- ELISA is a classical example of heterogeneous assay.

ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA)

ELISA is so named because of its two components:

- **Immunosorbent:** Here, an absorbing material is used (e.g. polystyrene, polyvinyl) that specifically absorbs the antigen or antibody present in serum.
- **Enzyme** is used to label one of the components of immunoassay (i.e. antigen or antibody).

Substrate-chromogen system: A substrate-chromogen system is added at the final step of ELISA.

TABLE 12.2: Immunoassays and the types of molecule used for labeling

Abbreviation	Immunoassay method	Molecules used for labeling	Type of visible effect
ELISA	Enzyme-linked immunosorbent assay	Enzyme	Color change is detected by spectrophotometer
IFA	Immunofluorescence assay	Fluorescent dye	Emits light, detected by fluorescence microscope
RIA	Radioimmunoassay	Radioactive isotope	Emits β and γ radiations, detected by β and γ counters
CLIA	Chemiluminescence-linked immunoassay	Chemiluminescent compounds	Emits light, detected by luminometer
IHC	Immunohistochemistry	Enzyme or fluorescent dye	Color change (naked eye) or fluorescence microscope
WB	Western blot	Enzyme	Color band (naked eye)
Rapid test	Immunochromatographic test	Colloidal gold or silver	Color band (naked eye)
	Flow-through assay	Protein A conjugate	Color band (naked eye)
IEM	Immunoferritin electron microscopy	Electron dense molecules (e.g ferritin)	Appears as black dot under electron microscope

TABLE 12.3: Enzymes used in ELISA and their substrate–chromogen system

Enzyme	Substrate	Chromogen
Horseradish Peroxidase	Hydrogen peroxide	Tetramethyl benzidine (TMB)
Urease	Urea	Bromocresol
β-Galactosidase	ONPG	ONPG
Alkaline Phosphatase	pNPP*	pNPP*

*para-Nitrophenyl phosphate is a chromogenic substrate, converted to para-Nitrophenol (color product)

- The enzyme reacts with the substrate, which in turn activates the chromogen to produce a color.
- Sometime, the substrate is chromogenic in nature (e.g. pNPP). On reaction with the enzyme, it changes its color (Table 12.3).
- The color change is detected by spectrophotometry in an ELISA reader. Intensity of the color is directly proportional to the amount of detection molecule (Ag or Ab) present in test serum.

(Ag-Ab complex)-enzyme + substrate → activates the chromogen → color change → detected by spectrophotometry

ELISA is usually performed on a microtiter plate containing 96 wells (micro-ELISA) (Fig. 12.14) or less commonly performed in tubes (macro-ELISA). The microtiter plate or the tubes are made up of polystyrene, polyvinyl or polycarbonate material.

ELISA kits are commercially available; contain all the necessary reagents (such as enzyme conjugate, dilution buffer, substrate/chromogen etc).The procedure involves a series of steps done sequentially; at each step, a reagent is being added, and then incubated followed by washing of the wells (manually or by an automated ELISA washer).

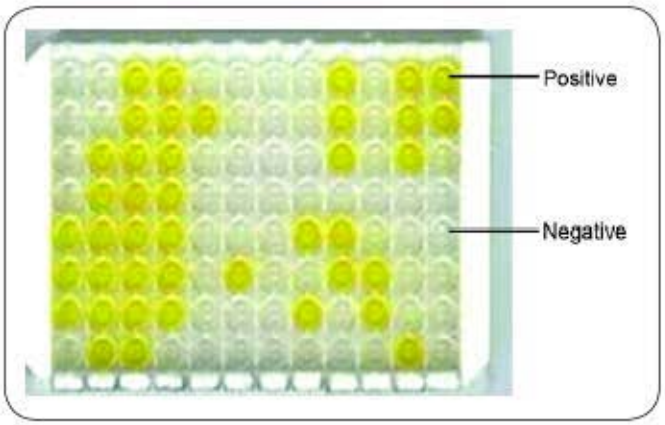

Fig. 12.14: ELISA done in a microtiter plate containing 96 wells (8X12)

TABLE 12.4: Principles of different ELISA types

ELISA type	Used for detection of	Enzyme is labeled with
Direct ELISA	Antigen	Primary antibody
Indirect ELISA	Antibody or antigen	Secondary antibody
Sandwich ELISA	Antigen	Primary antibody in direct sandwich ELISA Secondary antibody in indirect sandwich ELISA
Competitive ELISA	Antigen or antibody	Secondary antibody
ELISPOT	Cells producing antibody or cytokine	Primary antibody

Note: Primary antibody is directed against the antigen, secondary antibody is an antihuman (or other species) Ig directed against Fc region of any human/other species Ig

Types of ELISA

There are several types of ELISA, which differ from each other in their principles (Table 12.4).

Direct ELISA

It is used for detection of antigen in test serum. Here, the primary antibody (targeted against the serum antigen) is labeled with the enzyme.

- **Step 1:** Wells of microtiter plate are empty, not precoated with Ag or Ab.
- **Step 2:** Test serum (containing antigen) is added into the wells. Antigen becomes attached to the solid phase by passive adsorption.
- **Step 3:** After washing, the enzyme-labeled primary antibodies (raised in rabbits) are added.
- **Step 4:** After washing, a substrate–chromogen system is added and color is measured.

Well + Ag (test serum) + primary Ab-Enzyme + substrate-chromogen → Color change (Fig. 12.15)

Indirect ELISA

It is used for detection of antibody or less commonly antigen in serum. It differs from the direct ELISA in that the secondary antibody is labeled with enzyme instead of primary antibody. The secondary antibody is an anti-species antibody, e.g., anti human Ig (an antibody targeted to Fc region of any human Ig).

Indirect ELISA for antibody detection

- **Step 1:** The solid phase of the wells of microtiter plates are precoated with the Ag.

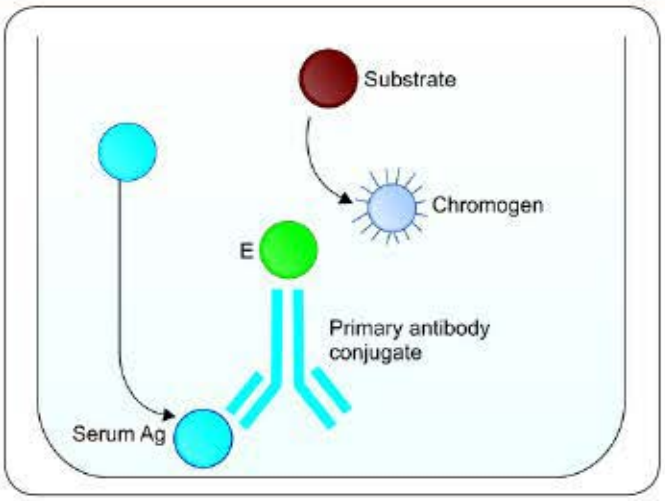

Fig. 12.15: Direct ELISA

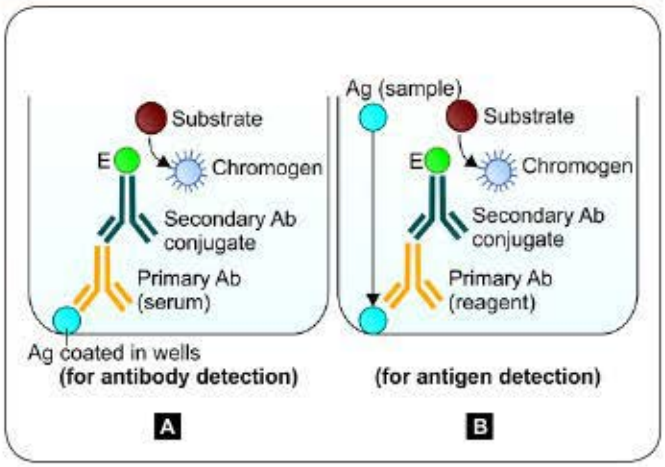


Figs 12.16A and B: Indirect ELISA. **A.** For antibody detection; **B.** For antigen detection

- **Step 2:** Test serum (containing primary Ab specific to the Ag) is added to the wells. Ab gets attached to the Ag coated on the well.
- **Step 3:** After washing, enzyme-labeled secondary Ab (anti-human immunoglobulin) is added.
- **Step 4:** After washing, a substrate-chromogen system is added and color is developed.

Wells are coated with Ag + primary Ab (test serum) + secondary Ab-Enzyme + substrate- chromogen → development of color (Fig. 12.16)

Indirect ELISA for antigen detection: Here, the wells are empty, not precoated with Ag or Ab.

- **Step 1:** The test antigen (serum) is added to the well. The Ag gets absorbed onto the well.
- **Step 2:** The primary antibody raised in rabbits (reagent) is added. The Ag binds to the primary antibody.
- **Step 3:** After washing, enzyme-labeled secondary Ab (anti-rabbit Ab) is added.
- **Step 4:** After washing, a substrate–chromogen system is added and color is developed.

Sandwich ELISA

It detects the antigen in test serum. It is so named because the antigen gets sandwiched between a capture antibody and a detector antibody. There are two types of sandwich ELISA-direct and indirect, depending upon whether the detector antibody is a primary antibody (direct) or secondary antibody (indirect).

Direct Sandwich ELISA

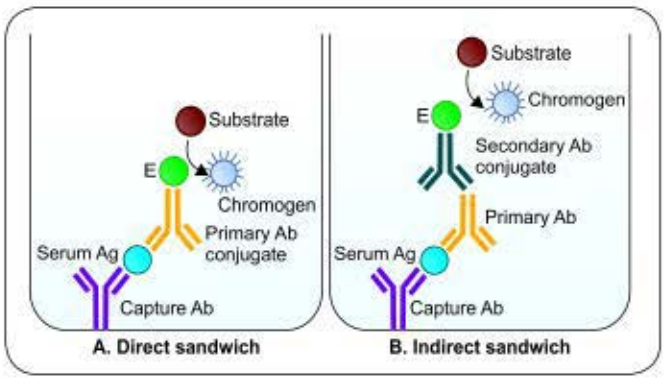
- **Step 1:** The microtiter well is precoated with the capture antibody (monoclonal Ab raised in rabbit) targeted against the test antigen.
- **Step 2:** The test serum (containing antigen) is added to the wells. Ag gets attached to the capture antibody coated on the well.
- **Step 3:** After washing, an enzyme labeled primary 'detector antibody' specific for the antigen is added. The detector antibody can be same as the capture antibody.
- **Step 4:** After washing, a substrate–chromogen system is added and color is developed.

Wells coated with capture Ab + Ag (test serum) + primary Ab-enzyme + substrate–chromogen → color (Fig. 12.17A)

In Indirect Sandwich ELISA

The primary antibody and the capture antibody belong to different species. More so, the primary antibody is not labeled with enzyme. Another enzyme-labeled secondary antibody targeted against the primary antibody is added. Thus, it is more specific than direct sandwich ELISA.

Wells coated with capture Ab + Ag (test serum) + primary Ab + secondary Ab- enzyme + substrate- chromogen → color (Fig. 12.17B)



Figs 12.17A and B: Sandwich ELISA (for antigen detection)

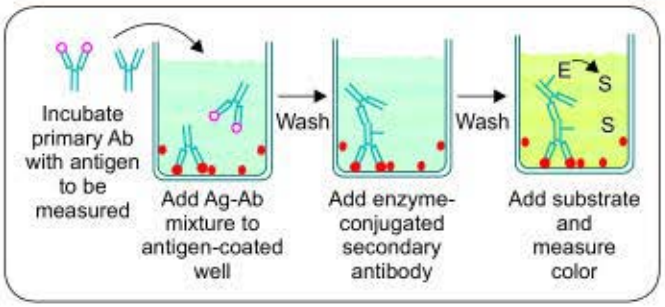


Fig. 12.18: Competitive ELISA for antigen detection

Competitive ELISA

Competitive ELISA is so named because, antigen in test serum competes with another antigen of same type coated on well to bind to the primary antibody.

- **Step 1:** Primary antibody is first incubated in a solution with a serum sample containing the test antigen.
- **Step 2:** This antigen–antibody mixture is then added to the microtiter well precoated with the same type of antigen.
- **Step 3:** The free antibodies bind to the antigen coated on the well. More the test antigens present in the sample, lesser free antibodies will be available to bind to the antigens coated onto well.
- **Step 4:** After washing (to remove free antibodies and antigens), enzyme-conjugated secondary antibody is added.
- **Step 5:** After washing, a substrate–chromogen system is added and color is developed. Intensity of the color is inversely proportional to the amount of antigen present in the test serum (Fig. 12.18).

The competitive ELISA can also be used for the detection of antibody in serum. More so, different formats of competitive ELISA are available such as direct, indirect and sandwich formats. The example given above is an indirect competitive ELISA format used for antigen detection (Fig. 12.18).

ELISPOT Test

It is modification of ELISA that allows the quantitative detection of cells producing antibodies (plasma cells) or cytokines (e.g. macrophage). ELISPOT used for quantitating the cytokine producing cells is described below (Fig. 12.19).

- Microtiter well is coated with the capture antibody specific for the cytokine.
- A suspension of the cell population under investigation is then added to the coated wells and incubated.
- The sensitized cells capable of producing the cytokines settle onto the surface of the well.

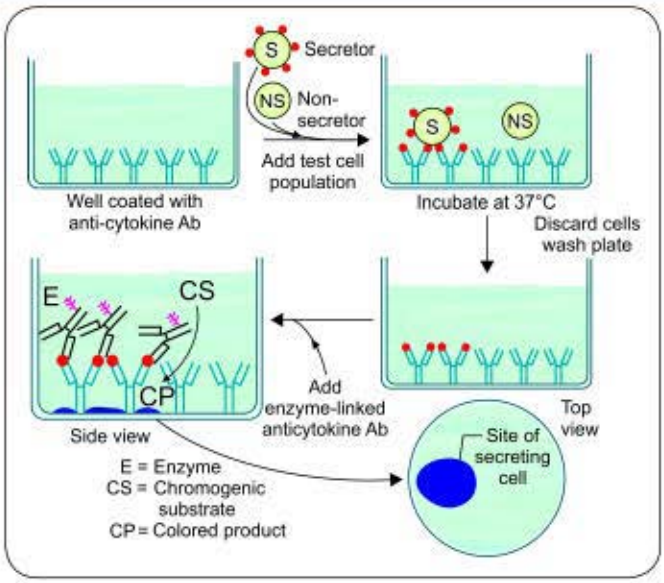

Fig. 12.19: ELISPOT test (for cytokine detection)

- The released cytokines are bound by the capture antibodies in the vicinity of the secreting cells, producing a ring of antigen–antibody complexes around each cell that is producing the cytokine of interest.
- After the incubation period, the well is washed and an enzyme-labeled anticytokine antibody is added.
- After washing away unbound antibody, a chromogenic substrate that forms an insoluble colored product is added. The colored product (purple) precipitates and forms a spot only on the areas of the well where cytokine-secreting cells have been deposited.
- **Quantitation:** The number of colored spots corresponds to the number of cytokine producing cells present in the added cell suspension.

For quantitative detection of antibody producing cells, the procedure is similar except that the wells are coated with capture antigen which would bind to the antibodies produced by the cells.

Advantage of ELISA

ELISA is the method of choice for detection of antigens/antibodies in serum in modern days, especially in big laboratories as large number of samples can be tested together using the 96 well microtiter plate.

- It is economical, takes 2–3 hours for performing the assay.
- ELISA is the most sensitive immunoassay, i.e. why, it is commonly used for performing screening test at blood banks and tertiary care sites.
- Its specificity used to be low. But now, with use of more purified recombinant and synthetic antigens, and monoclonal antibodies, ELISA has become more specific.

Disadvantage of ELISA

- In small laboratories having less sample load, ELISA is less preferred than rapid tests as the later can be done on individual samples.
- It takes more time (2–3 hours) compared to rapid tests which take 10–20 min.
- It needs expensive equipments such as ELISA washer and reader.

Applications of ELISA

ELISA can be used both for antigen and antibody detection.

- ELISA used for antigen detection: Hepatitis B [hepatitis B surface antigen (HBsAg) and precore antigen (HBeAg)], NS1 antigen for dengue, etc.
- ELISA can also be used for antibody detection against hepatitis B, hepatitis C, HIV, dengue, EBV, HSV, toxoplasmosis, leishmaniasis, etc.

IMMUNOFLUORESCENCE ASSAY

It is a technique similar to ELISA, but differs by some important features:

- Fluorescent dye is used instead of enzyme for labeling of antibody.
- It detects cell surface antigens. It is also used to detect antibodies bound to cell surface antigens, unlike ELISA which detects free antigen or antibody.

Principle

Fluorescence refers to absorbing high energy-shorter wavelength ultraviolet light rays by the fluorescent compounds and in turn emitting visible light rays with a low energy-longer wavelength.

- The fluorescent dye is used to conjugate the antibody and such labeled antibody can be used to detect the antigens or antigen–antibody complex on the cell surface.
- The fluorescent compounds commonly used-fluorescein isothiocyanate (FITC).

Types

Direct Immunofluorescence Assay

- **Step 1:** Sample containing cells carrying surface antigens is smeared on a slide.
- **Step 2:** Primary antibody specific to the antigen, tagged with fluorescent dye is added.
- **Step 3:** Slide is washed to remove the unbound antibodies and then viewed under a fluorescence microscope (Fig. 12.20A).

Indirect Immunofluorescence Assay

This detects antibodies in sample. Slides smeared with cells carrying known antigens are commercially available.

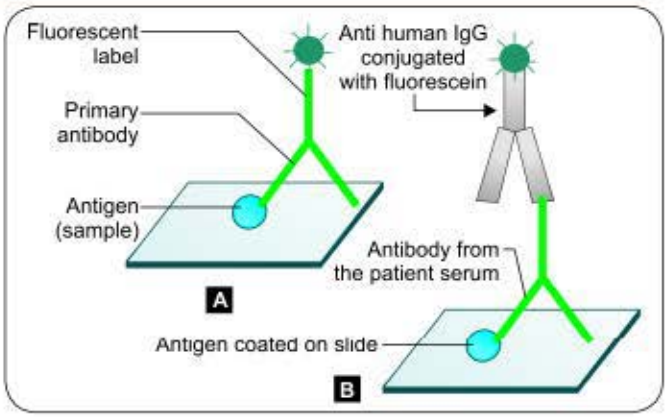

Fig. 12.20: Immunofluorescence assay. **A.** Direct; **B.** Indirect

- **Step 1:** Test serum containing primary antibody is added to the slide.
- **Step 2:** Slide is washed to remove the unbound antibodies. A secondary antibody (antihuman antibody conjugated with fluorescent dye) is added.
- **Step 3:** Slide is washed and then viewed under a fluorescence microscope (Fig. 12.20B).

Applications: Immunofluorescence assay has various applications, such as:

- Detection of autoantibodies (e.g. antinuclear antibody) in autoimmune diseases.
- Detecting microbial antigens, e.g. rabies antigen in corneal smear
- Detection of viral antigens in cell lines inoculated with the specimens.

Flow Cytometry

Flow cytometry is a laser-based technology that quantitatively analyses and separates the cells as they pass through the laser beam. Its advanced and upgraded form is called as fluorescence-activated cell sorting (FACS).

Principle (Fig. 12.21): Cells (e.g. CD4 T cells) coated with specific fluorescent tagged antibodies (e.g. anti-CD4) are mixed with sheathed fluid and are passed through a special instrument called ultrasonic nozzle vibrator.

- The sheathed fluid aligns the cells so that they pass through the nozzle in a single row.
- The nozzle vibrator has a unique property of allowing only one cell to exit at a time.
- The cells after exiting from the nozzle pass through a beam of laser which excites the fluorescent dye on them resulting in emission of light.
- The cells based on their electrical charge are then passed through the electromagnetic deflection plates so that different cell types are collected in separate containers.

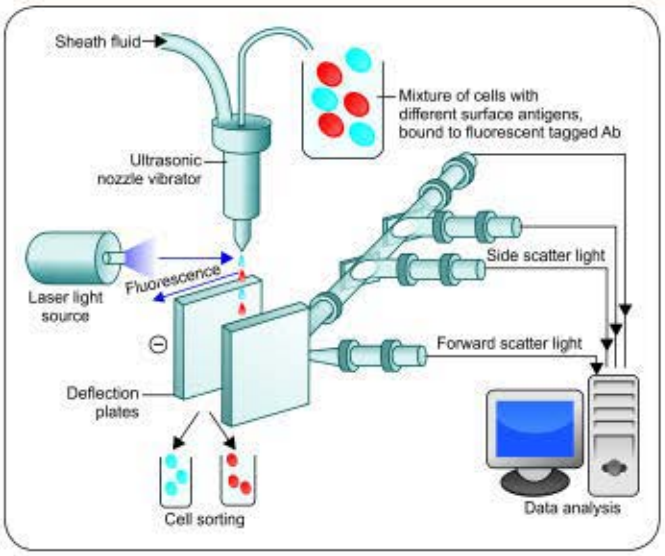

Fig. 12.21: Principle of flow cytometry

In flow cytometry, four important properties can be determined during the flow of cells—

1. **Cell counting:** Cells exit from the nozzle at a rate of more than thousand cells per second. Each time, a cell crosses the laser beam, fluorescent light is emitted which indicates the exit of a single cell from the nozzle. This property is exploited to count the number of cells that pass through the laser beam, e.g. CD4 T cell count in blood.
2. **Differentiating between two cells:** Two fluorochrome dyes (fluorescein and rhodamine) can be used in flow cytometry that label two different antibodies targeting two type of cells (e.g. CD4 and CD8 T cells). Each generates a different color light while passing through laser beam. Fluorescein coated cells emit green color and rhodamine coated cells emit red color light.
3. **Scattering:** The laser beam gets deflected each time a cell crosses it. The deflection may happen towards forward direction or lateral direction.
   - Forward scatter is proportional to size of the cell; larger cells have greater forward scatter.
   - Side scatter is proportional to intracellular complexity; cells with more granules (e.g. neutrophils) have more side scatter than cells with a simple cytoplasm (lymphocytes).
4. **Sorting out of cells:** The electromagnetic deflection plates help in separation of cells so that different cell types are collected in separate containers.

Applications: Flow cytometry can be used to analyse multiple parameters of cells (e.g. leukocytes) such as cell counting, cell sorting, analysis of size, shape, granularity, DNA or RNA content of a cell, etc. Important applications include—

- CD4 T cell count in HIV infected patients
- Detection of leukocyte with specific markers for the diagnosis of various lymphomas.

IMMUNOHISTOCHEMISTRY

Immunohistochemistry refers to the process of detecting antigens (e.g. proteins) in cells of a tissue section by exploiting the principle of using labeled antibodies binding specifically to the antigens in biological tissues.

- It can be based on principles of ELISA or IFA:
  - The antibody (directed against tissue antigen) is conjugated to an enzyme, such as peroxidase, that can catalyse a colour-producing reaction (immunoperoxidase staining).
  - Alternatively, the antibody can also be tagged to a fluorescent dye.
- It is widely used in the diagnosis of abnormal cells (e.g. tumor cells).

RADIOIMMUNOASSAY

Radioimmunoassay (RIA) is a very sensitive and specific technique that is used for quantitative detection of antigens such as hormones, proteins, drugs, vitamins and microbial antigens (e.g. HBsAg) at a concentration of <0.01 µg/ml. It was developed by Berson and Yalow (1960), for which they were awarded Nobel Prize in 1977. The principle of RIA is similar to that of competitive ELISA for antigen detection, except that in RIA, the radioactive molecules are used for labeling and the test is done in a liquid medium. Because of the radiohazard associated, the use of RIA is reduced.

CHEMILUMINESCENCE-LINKED IMMUNOASSAY (CLIA)

Chemiluminescence refers to the emission of light (luminescence), as a result of a chemical reaction. The principle of CLIA is similar to that of ELISA; however, the chromogenic substance is replaced by chemiluminescent compounds (e.g. luminol and acridinium ester) that generate light during a chemical reaction (luxogenic). The light (photons) can be detected by a photomultiplier, also called as luminometer.

Ag-Ab-[Luminol] + [hydrogen peroxide] → Ag-Ab-[Products]+light(photons) → detected by luminometer

Advantage of CLIA

CLIA claims to be 10 times more sensitive than ELISA.

- CLIA can be further modified by using an enhancer that potentiates the chemical reaction. This gives CLIA an overall improvement of 200 folds over ELISA.

- Most samples have no 'background' signal, i.e. luminol compounds do not themselves emit light.
- Measurement of chemiluminescence is not a ratio unlike the measurement of fluorescence (IFA) and or color (ELISA).
- Applications of CLIA are similar to those of ELISA.

WESTERN BLOT

Western blot detects specific proteins (antibodies) in a sample containing mixture of antibodies each targeted against different antigens of same microbe.

- It is so named for its similarity to Southern blot (detects DNA fragments) and Northern blot (detects mRNAs).
- **Eastern blot** is the latest addition to the list; it is a modification of Western blot, which detects the carbohydrate epitopes present on proteins or lipids.

Procedure

Western blot comprises of three basic components as follows (Fig. 12.22):

SDS PAGE: This is a method which separates complex protein antigen mixture into individual fragments. It has two steps.

1. **SDS:** The complex protein (antigen) mixture is treated with a strong denaturing detergent called SDS (*sodium dodecyl sulfate*).
2. **PAGE:** Then the mixture is subjected to polyacrylamide gel electrophoresis (PAGE) which separates the antigenic components according to their molecular weight; lower molecular weight components migrate farther than higher molecular weight ones.

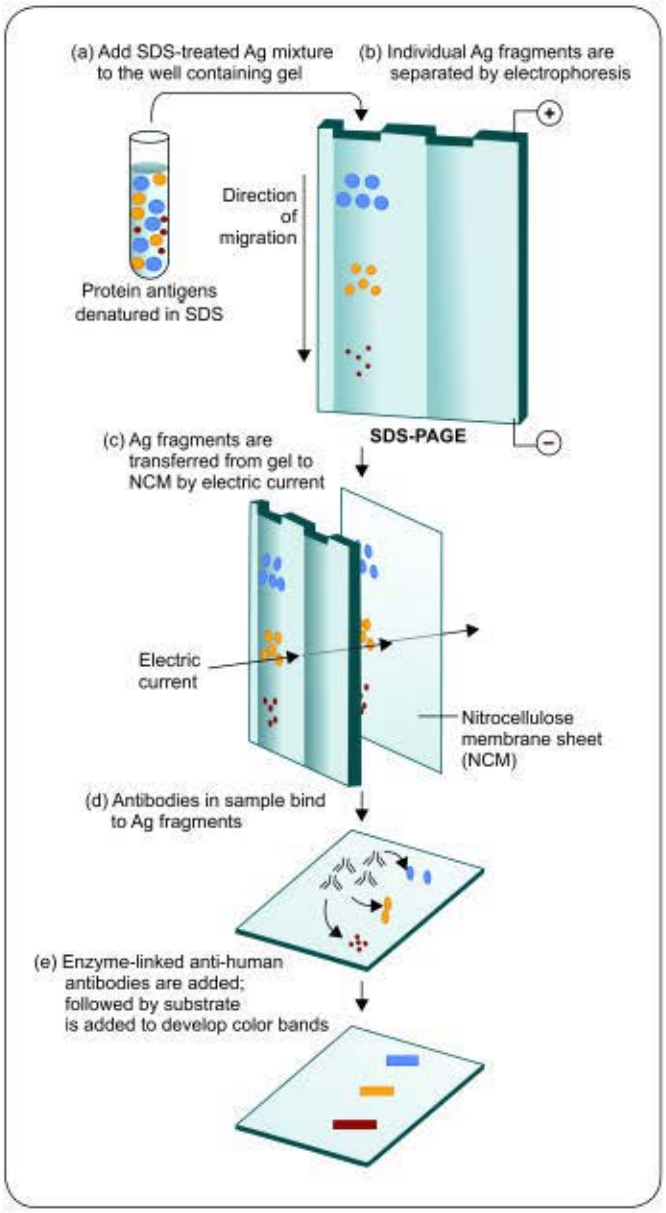
Nitrocellulose membrane (NCM) blotting: The gel is removed from the electrophoresis apparatus and placed over a protein-binding sheet such as nitrocellulose or nylon and the antigen fragments in the gel are transferred (blotted) to the NCM sheet by the passage of an electric current.

Enzyme immunoassay (to detect the antibodies):

- NCM strips containing protein antigen fragments are treated with patient's sample containing antibodies. Individual serum antibodies would bind to the respective antigen fragments, thus making western blot highly specific.
- Addition of enzyme-linked antihuman Ig, detects the individual serum antibodies bound to antigen fragments. Substrate/chromogen is added for development of colored bands.

Applications

Western blot has an excellent specificity. Hence, it is often used as a supplementary test to confirm the result of ELISA or other immunoassays having higher sensitivity. Western blot formats are available to detect antibody in various diseases such as HIV, Lyme's disease, Herpes simplex virus infection, cysticercosis, hydatid disease and toxoplasmosis.



(a) Add SDS-treated Ag mixture to the well containing gel
(b) Individual Ag fragments are separated by electrophoresis
Direction of migration
Protein antigens denatured in SDS
SDS-PAGE
(c) Ag fragments are transferred from gel to NCM by electric current
Electric current
Nitrocellulose membrane sheet (NCM)
(d) Antibodies in sample bind to Ag fragments
(e) Enzyme-linked anti-human antibodies are added; followed by substrate is added to develop color bands

Fig. 12.22: Western blot (principle)

RAPID TEST

Rapid tests are revolutionary in the diagnosis of infectious diseases. They are very simple to perform (one step method), rapid (takes 10–20 minutes), require minimal training, does not need any sophisticated instruments.

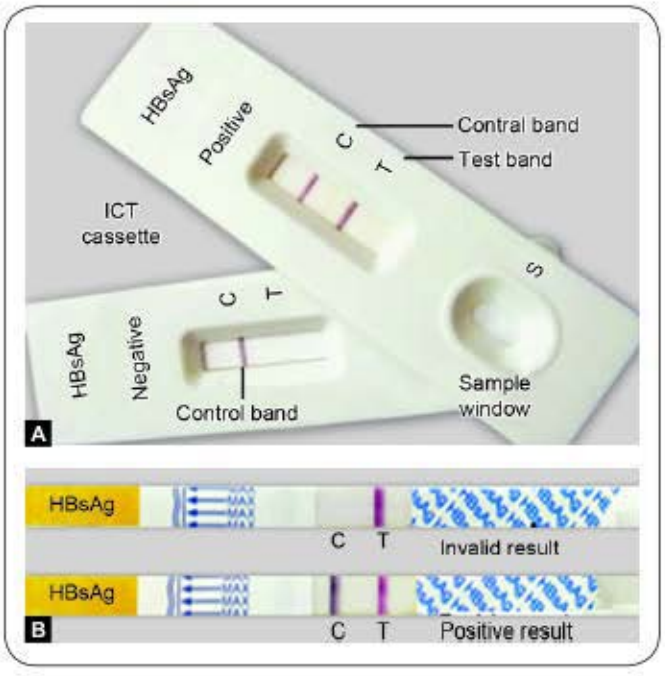
- These tests are also called **Point-of-care** (POC) tests, because unlike ELISA and other immunoassays, the POC tests can be performed independent of laboratory equipment and deliver instant results.
- Two principles of rapid tests are available—lateral flow assay and flow through assay.
- Both the formats are available for the diagnosis of various diseases such as malaria, hepatitis B, hepatitis C, HIV, leptospirosis, *Helicobacter pylori*, syphilis, etc.

Immunochromatographic Test (Lateral Flow Assay)

Immunochromatographic test (ICT) is based on lateral flow technique. It is widely used in diagnostic laboratories because of its simplicity, economy and rapidity. It can be used for both antigen and antibody detection in sample. Principle of antigen detection method is described below.

Principle of ICT (Antigen Detection)

The test system consists of a nitrocellulose membrane (NCM) and an absorbent pad. Two formats are available: cassette or strip (Fig. 12.23). The NCM is coated at two places in the form of lines—a test line, coated with monoclonal antibody targeted against the test antigen and a control line, coated with antihuman immunoglobulin. Specific Ab against the target Ag labelled with chromogenic marker (specific Ab tagged with *colloidal gold or silver*, a visually detectable marker) is infiltrated in the absorbent pad lining the sample window.



Figs 12.23A and B: ICT for HBsAg detection. **A.** Cassette format; **B.** Strip format

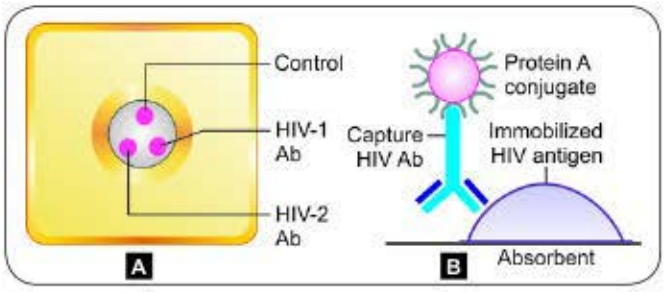
- The sample (serum) containing the test antigen is added to sample well; it reacts with antibody labeled with chromogenic marker (*colloidal gold* or *silver*, a visually detectable marker).
- Both 'Ag-specific Ab-colloidal gold complex' as well as the 'free colloidal gold labeled Ab' move laterally along the nitrocellulose membrane.
- **Test band:** At the test line, the Ag-labeled Ab complex is immobilized by binding to the monoclonal Ab in the test line to form a colored band (Fig. 12.23).
- **Control band:** The free colloidal gold labeled Ab can move further and binds to the anti-human Ig to form a color control band. If the control band is not formed, then the test is considered invalid irrespective of whether the test band is formed or not (Fig. 12.23).

Flow-through Assay

Flow-through tests are another type of rapid diagnostic assays which differ from ICT in two aspects: (1) protein A is used for labeling antibody instead of gold conjugate and (2) the sample flows vertically through the nitrocellulose membrane (NCM) as compared to lateral flow in ICT.

Flow-through tests can be used for both antigen and antibody detection. HIV TRIDOT test is a classical example (described below, Fig. 12.24A). It detects antibodies to HIV-1 and 2 separately in patient's serum.

- The test system is in a cassette format, consisting of a NCM and an absorbent pad. The NCM is coated at three regions- two test regions coated with HIV-1 and 2 antigens and a third control region coated with antihuman Ig.
- Sample and buffer reagents are added sequentially from the top following which they pass through the membrane and excess fluid is absorbed into the underlying absorbent pad.
- As the patient's sample passes through the membrane, HIV antibodies, if present bind to the immobilized antigens (Fig. 12.24B).
- **Test dots:** Protein-A conjugate (present in buffer) binds to the Fc portion of the HIV antibodies to give distinct pinkish purple DOT(s), separately for HIV-1 and 2 antibodies.



Figs 12.24A and B: Flow-through assays. **A.** HIV TRI-DOT assay for HIV 1 and 2 antibodies detection; **B.** Principle of HIV TRI-DOT

- **Control dot:** Irrespective of whether the HIV antibodies are present or not, protein-A can bind to any IgG present in serum and the IgG-protein A complex can further bind to the antihuman Ig at the control line to give a pinkish purple DOT.

TECHNIQUES USING ELECTRON MICROSCOPE

Immunoferritin Test

In electron microscopy, the electron dense areas appear darker than other areas. Electron dense molecules such as ferritin particle can be used to label an antibody which can bind to surface antigens of cells and tissues. When visualized under electron microscope, the electron dense label absorbs more electrons and appears as small black dot, thus confirming the presence of antigen.

Immunoelectron Microscopy

Viral particles appear to be clumped when mixed with specific antisera and observed under the electron microscope. This is used for finding hepatitis A virus and rotavirus particles from stool specimen.

EXPECTED QUESTIONS

I. Essay:

1. Enumerate the properties and types of antigen antibody reactions. Describe in detail about the principle, types, and applications of ELISA?
2. Describe in detail about the principle, types, and applications of agglutination reaction?

II. Write short notes on:

1. Indirect immunofluorescence assay
2. Flow cytometry
3. Western blot
4. Immunochromatographic test
5. Affinity and avidity of antibody
6. Prozone phenomena

III. Multiple Choice Questions (MCQs):

1. Nagler reaction is example of:
   a. Precipitation
   b. CFT
   c. Agglutination
   d. Neutralization

2. Paul Bunnell test is example of:
   a. Agglutination
   b. Precipitation
   c. Neutralization
   d. CFT

3. All are precipitation reactions except:
   a. VDRL test
   b. Kahn test
   c. Widal test
   d. Ascoli's test

4. The following methods of diagnosis utilize labeled antibodies except:
   a. ELISA (Enzyme Linked Immunosorbent Assay)
   b. Radioimmunoassay
   c. Hemagglutination inhibition test
   d. Immunofluorescence

5. Prozone phenomenon is due to:
   a. Excess antigen
   b. Excess antibody
   c. Hyperimmune reaction
   d. Both antigen and antibody excess

Answers

1. d **2.** a **3.** c 4. c **5.** b

CHAPTER 13

Complement

Chapter Preview

- General properties
- Complement pathways
- Effector functions of complement
- Regulation of complement pathways
- Complements deficiencies

GENERAL PROPERTIES

The term 'complement' (C) represents a group of proteins normally found in serum in inactive form, but when activated they augment the immune responses. They constitute about 5% of normal serum proteins and their level does not increase following either infection or vaccination.

Complements have the following general properties:

- **Bind to Fc region of antibody:** The effector function of complement is mediated by binding with Fc portion of antibody. The binding of complement to an antibody is described by various terms as, **fixing** or **consumption** (as it disappears from serum following binding).
- **Role of antigen:** The classical pathway complements do not bind to free antibodies but they can only fix to those antibodies which are bound with antigens. However fixation of complement is not influenced by the nature of antigens, but only by the class of antibody.
- **Species nonspecific:** Complements are present in the sera of all mammals, birds, amphibians and fish. Complements from one species can react with antibodies from other species, though the efficiency decreases with increase in taxonomic distance.
- **Heat labile:** Complements get denatured by heating the serum at 56°C for 30 minutes. Such serum with lost complement activity is called **inactivated serum**.

History

The role of complement in mediating lysis of target cells (e.g. hemolysis and bacteriolysis), was described since nineteenth century.

- Pfeiffer (1894) discovered the complement mediated lysis of *Vibrio cholerae* in immunized guinea pigs. Bacteriolysis in *vivo* was known as Pfeiffer's phenomenon.
- Jules Bordet named it as alexine which was later called complement by Ehrlich.

Complement Components

The complement system comprises of about 30 serum proteins grouped into complement components, the properdin system and the regulatory proteins.

- The complement components are named by numerals. There are nine components; C1 to C9. C1 has three subunits—C1q, C1r and C1s.
- The properdin system and the regulatory proteins are named by letter symbols, e.g. factor-B.

Synthesis

Liver is the major site of synthesis of complement proteins. Other minor sites include blood monocytes, tissue macrophages, and epithelial cells of GIT and genitourinary tract.

Complement Activation

All the complement proteins are synthesized in inactive form (e.g. zymogens) and are activated by proteolysis.

- Complements have two unequal fragments (large and small fragment).
- The larger fragments are usually designated as 'b' (e.g. C3b) and the smaller fragments are designated as 'a' (e.g. C3a). An exception is C2a which is larger fragment.
- During proteolysis, the smaller fragment is removed exposing the active site of the larger fragment.
- The larger fragment participates in the cascade reaction of complement pathway and the smaller fragment diffuses away to mediate other functions.
- **Cascade reaction:** The fragments of complements interact in a definite sequential manner with a cascade like effect, which leads to formation of complex. Such complex having enzymatic activity is designated by putting a bar over the number or symbol (e.g. $\overline{CbBb}$).

COMPLEMENT PATHWAYS

There are three pathways of complement activation.

1. **Classical pathway:** This is an antibody dependent pathway. Pathway is triggered by the antigen–antibody complex formation.
2. **Alternative pathway:** This is an antibody independent pathway, triggered by the antigen directly.
3. **Lectin pathway:** This is a recently described pathway. It resembles classical pathway, but it is antibody independent.

Stages of complement activation

There are four main stages in the activation of any of the complement pathways.

1. Initiation of the pathway
2. Formation of C3 convertase
3. Formation of C5 convertase
4. Formation of membrane attack complex (MAC)

All the three pathways (Fig. 13.1) differ from each other in their initiation till formation of C3 convertase. Then, the remaining stages are identical in all the pathways.

CLASSICAL PATHWAY

Classical pathway is antibody dependent. However, not all antibodies can bind to complements of classical pathway. Decreasing order of ability of antibodies to fix complement is—IgM (most potent) > IgG3 > IgG1 > IgG2. The other classes of antibodies do not fix complements. C_H2 domain on IgG, C_H4 on IgM participate in complement binding. The classical pathway begins with activation of C1 and binding to antigen–antibody complex.

Initiation

The first step is the binding of C1 to the antigen–antibody complex (Fig. 13.1).

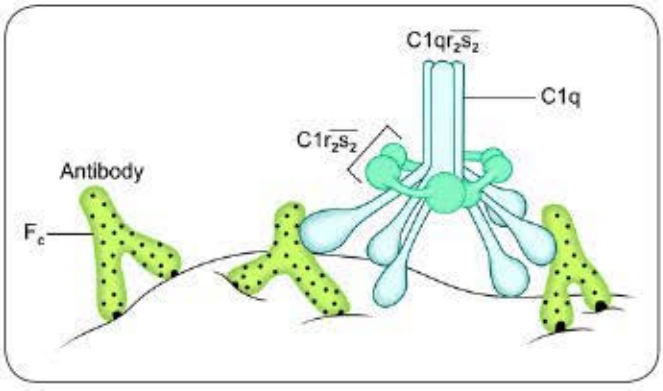


Fig. 13.1: Activation of C1 (initiation step of classical complement pathway)

- The first binding portion of C1 is C1q, which reacts with the Fc portion of IgM or IgG bound to antigen.
- C1q is a hexamer having six globular heads each acting as a combining site.
- Effective activation of classical pathway begins only when C1q is attached to the Fc portion of antibody by at least two of its globular binding sites.
  - IgM being pentameric, has five Fc regions, hence one molecule of IgM can initiate the pathway.
  - Whereas IgG is monomeric, therefore two IgG molecules are needed to initiate the process. Hence IgM is much efficient stimulator of classical pathway.
- C1q binding in the presence of calcium ions, in turn activates sequentially C1r followed by C1s.

Formation of C3 Convertase

Activated $\overline{C1s}$ acts as an esterase (C1s esterase), which can cleave C4 to produce C4a (an anaphylatoxin), and C4b which binds to C1 and participates further in complement cascade.

- $\overline{C14b}$ in the presence of magnesium ions cleaves C2 into C2a, which remains linked to complement complex, and C2b (has kinin like activity), which is released outside.
- $\overline{C14b2a}$ is referred to as C3 convertase of the classical pathway.

Formation of C5 Convertase

C3 convertase hydrolyses many C3 molecules into two fragments: C3a (an anaphylatoxin) and C3b which remains attached to $\overline{C14b2a}$ to form $\overline{C14b2a3b}$ complex, which acts as C5 convertase of classical pathway.

Formation of Membrane Attack Complex

This phase begins with C5 convertase cleaving C5 into C5a (an anaphylatoxin, released into the medium) and C5b, which continues with the cascade.

- $\overline{C5b}$ is extremely labile, gets stabilized by binding soon with C6 and C7 to form $\overline{C5b67}$ followed by addition of C8.
- The hydrophobic regions on C7 and C8 help in penetration into the target cell membrane.
- This inserted membrane complex ($\overline{C5b678}$) has a catalytic property to bind to C9 molecule and then it polymerizes the C9 into a tubular channel of 10 nm diameter.
- Penetration of C9 causes formation of channels or pores on the target cell membrane.
- Each tubular channel behaves hydrophobic outside, but hydrophilic inside; thus allowing free passage of ions and water into the cell leading to cellular swelling and lysis.
- Because $\overline{C5b6789}$ destroys the target cell by attacking the cell membrane; hence it is called membrane attack

complex (MAC) and the process of cytolysis is referred to as complement-mediated cytotoxicity (Figs 13.2 and 13.3).

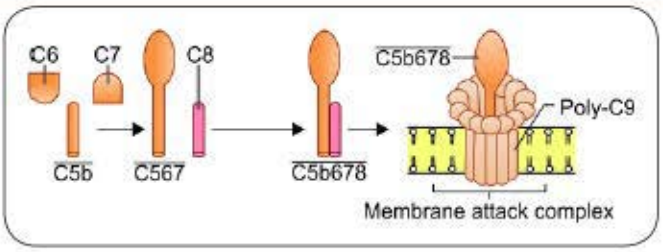

Fig. 13.2: Formation of membrane attack complex

ALTERNATIVE PATHWAY

Alternative pathway (Fig. 13.3) is independent of antibody; hence is considered as a part of innate immunity. It also goes through the four stages; but differs from the classical pathway in first two stages. Unlike the classical pathway

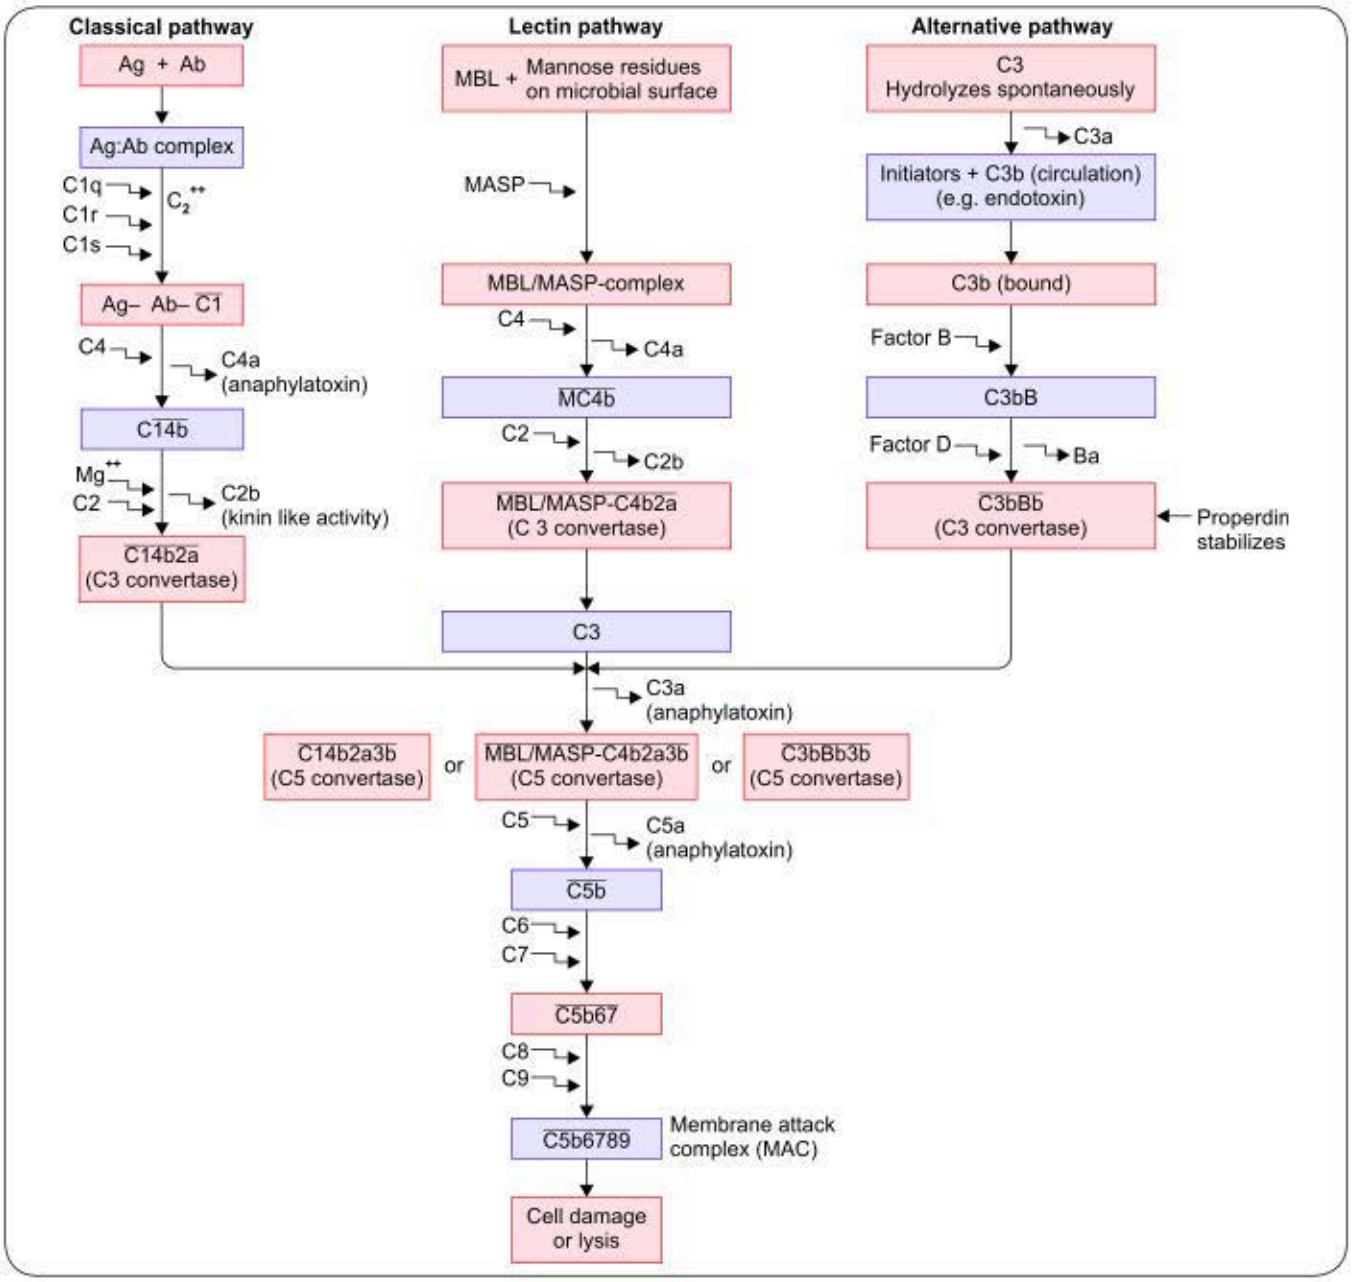

Fig. 13.3: The complement pathways

Abbreviations: MBL, mannose binding lectins; MASP, MBL-associated serine protease

TABLE 13.1: Initiators for alternative pathway

Antigens from pathogen	Nonmicrobial initiators
Endotoxin or LPS (lipopolysaccharide) from gram-negative bacteria	Human antibodies in complexes—IgA, IgD
Teichoic acid from gram-positive bacteria	Tumor cells
Fungal cells	Cobra venom factor
Yeast cells	Heterologous RBCs from mouse, rabbit and chicken
Parasites like trypanosomes	Anion polymer like dextran sulfate
Virus-infected cells	Pure carbohydrates like agar and inulin

which involves all complement components from C1 to C9; in alternative pathway three complement components C1, C4 and C2 are not involved. Instead, it requires three other complement proteins present in serum named factor B, factor D and properdin.

Initiation

The alternative complement cascade is initiated by various cell surface constituents that are foreign to the host, e.g. bacterial endotoxin (Table 13.1).

The first complement component to be involved in alternative pathway is free C3 in the serum. C3 hydrolyzes spontaneously, to generate:

- C3a which diffuses out and;
- C3b fragment which attaches to foreign cell surface antigen.

Formation of C3 Convertase

- In the next step, **Factor B** binds to C3b coated foreign cells.
- **Factor D**, another alternative pathway complement factor, acts on factor B, and cleaves it into Ba (diffuses out) and Bb (remains attached).
- $\overline{C3bBb}$ is also called C3 convertase of alternative pathway.
- $\overline{C3bBb}$ has a very short half life of 5 minutes. If it is stabilized by another complement protein called properdin its half-life is increased to 30 minutes.

The remaining two stages, i.e. formation of C5 convertase and formation of membrane attack complex are identical to that of classical pathway.

LECTIN PATHWAY

Lectin pathway is another complement pathway of innate immunity described recently, that works independent of antibody.

- It is mediated through lectin proteins of the host that interact with mannose residues present on microbial surface; hence the name lectin pathway.
- Among the four stages, the first stage differs from classical pathway.
- Lectin pathway involves all complement components used for classical pathways except C1 (i.e. from C2 to C9); Instead of C1, host lectin protein called mannose binding lectins mediate the first 'initiation' stage (Fig. 13.3).

Initiation

Antigens that activate lectin pathway are the mannose carbohydrate residues of glycoproteins present on microbial surfaces.

- A specific host lectin protein called mannose binding lectins (MBL) bind to mannose residues on microbial surface.
- MBL is an acute phase reactant protein, similar to C1q in structure.
- After binding of MBL to microbial surface, another host protein called MBL-associated serine protease (MASP) gets complexed with MBL.
- MASP is similar or C1r and C1s and mimics their functions.
- The remaining three stages are similar to the classical pathway.
- The MBL–MASP complex cleaves C4 which in turn splits C2 and the $\overline{MBL/MASP\text{-}C4b2a}$ acts as C3 convertase.

Important differences between the three complement pathways are summarized in Table 13.2.

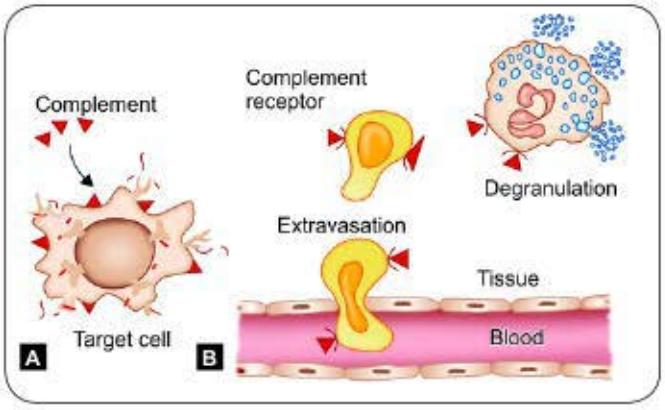
TABLE 13.2: Differences between the three complement pathways

Features	Classical pathway	Alternative pathway	Lectin pathway
Activator (initiator)	Antigen–antibody complex	Endotoxin IgA, IgD, cobra venom, Nephritic factor	Carbohydrate residue of bacterial cell wall (mannose binding protein) that binds to host lectin antigen.
First complement activated	C1	C3b	C4
C3 convertase	$\overline{C14b2a}$	$\overline{C3bBb}$	$\overline{MBL/MASP\text{-}C4b2a}$
C5 convertase (C3 convertase + 3b)	$\overline{C14b2a3b}$	$\overline{C3bBb3b}$	$\overline{MBL/MASP\text{-}C4b2a3b}$
Complement levels in the serum	All C1-C9: Low	▪ C1,C4,C2: Normal ▪ Others: Low	▪ C1: Normal ▪ Others: Low
Immunity	Acquired	Innate	Innate

EFFECTOR FUNCTIONS OF COMPLEMENT

The membrane attack complex (MAC) and other complement by-products produced during the activation of complement pathways augment the immune response in many ways; which are collectively called the effector functions of complement products. The functions are as follows:

1. **Target cell lysis by MAC:** As already explained, the MAC makes pores or channels in the target cell membrane; thereby allows the free passage of various ions and water into the cell leading to cell swelling, lysis and death. Bacteria, enveloped viruses, damaged cells, tumor cells, etc. are killed by this mechanism, commonly referred to as complement-mediated cell lysis (Fig. 13.4A).
2. **Inflammatory response:** Complement by-products such as C3a, C4a and C5a are called anaphylatoxins. They bind to surface receptors of mast cells and induce their degranulation leading to release of histamine and other inflammatory mediators. They cause vasoconstriction, and increased vascular permeability (Fig. 13.4B).
3. **Opsonization:** C3b and C4b act as major opsonins that coat the immune complexes and particulate antigens. Phagocytic cells express complement receptors (CR1, CR3 and CR4) for complement components (C3b, C4b), and are able to bind to complement coated antigens and enhance phagocytosis (Fig 13.5). C5a augments this process by enhancing the CR1 expression on phagocytes by 10 folds.
4. **Removing the immune complexes from blood:** C3b plays an important role in removing immune complexes from the blood. C3b bound immune complexes are recognized by complement receptor CR1 present on RBCs. Immune complexes bound to RBCs are taken to liver and spleen where they are phagocytosed after being separated from the RBCs (Fig. 13.6).
5. **Viral neutralization:** Complements play a crucial role in neutralization of the viruses; which occurs by many ways—
   - Complements coated on virus surfaces neutralize the viral infectivity by blocking their attachment sites.
   - C3b mediated opsonization of viral particles.
   - Lysis of the enveloped viruses either by activation of classical pathway (most viruses) or some time by alternative or lectin pathways (by some viruses like Epstein–Barr virus, rubella virus, etc.)



Figs 13.4A and B: A. Complement mediated cell lysis; **B.** Activation of inflammatory response

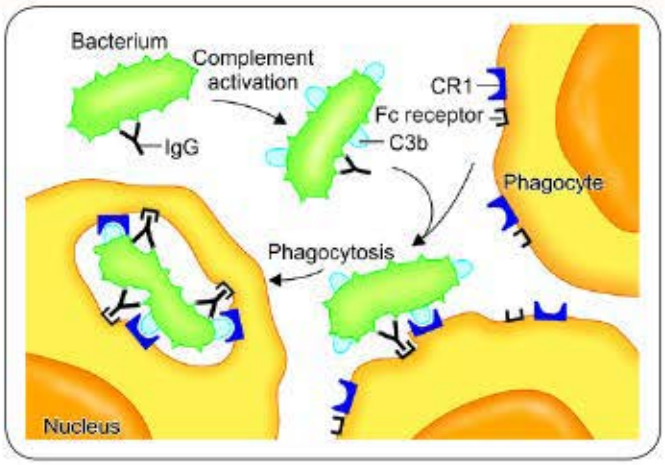


Fig. 13.5: Complement-mediated opsonization

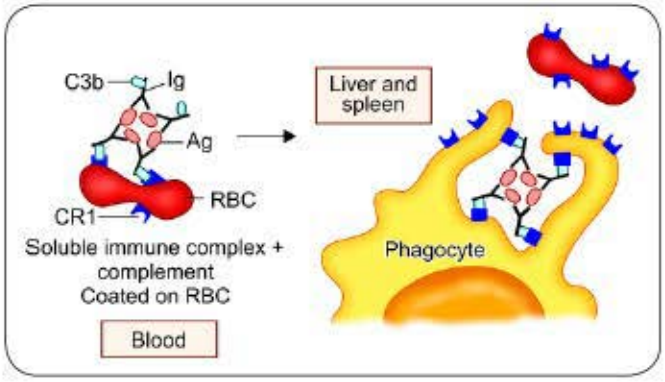

Fig. 13.6: Clearance of immune complexes

COMPLEMENT RECEPTORS

Complement receptors (CRs) play an important role in mediating the activities of complement products as well as in regulating their activities. They are distributed on various cell types and bind to specific ligands to mediate specific function (Table 13.3).

TABLE 13.3: Complement receptors—distribution, their ligands and functions

Complement receptors	Ligands	Distribution	Function
CR1 (CD35)	C3b, C4b	RBCs, phagocytes All blood cells	▪ Regulates complement pathway by inhibiting C3 convertase ▪ Helps in removal of immune complexes
CR2 (CD21)	C3d, C3dg	B cells, T cells, Follicular dendritic cells	▪ Forms a part of B cell co-receptor involved in humoral responses ▪ Acts as EBV receptor
CR3, CR4	iC3b	Phagocytes	▪ Opsonization ▪ Binding and extravasation of neutrophils
CR3a, CR4a, CR5a	C3a, C4a, C5a	Mast cells, Basophils	Degranulation of mast cells and basophils

Abbreviations: CR, complement receptors; EBV, Epstein-Barr virus; iC3b, inactivated C3b

Note: C3d and C3dg are generated during break down of C3b

EVASION OF COMPLEMENT SYSTEM BY MICROORGANISMS

In order to escape from the complement mediated effector mechanisms, microorganisms can develop various counter mechanisms to evade the complement system. (Table 13.4).

TABLE 13.4: Mechanisms of microbial evasion of complement system

Mechanisms	Examples
Shown by gram-negative bacteria	
Long polysaccharide side chain of bacteria can prevent membrane attack complex (MAC) insertion	*Escherichia coli* *Salmonella*
Noncovalent interactions between bacterial cell wall components can prevent MAC insertion	*Neisseria gonorrhoeae*
Elastases destroy C3a and C5a	*Pseudomonas*
Shown by gram-positive bacteria	
Thick peptidoglycan cell wall prevents MAC insertion	*Staphylococcus* *Streptococcus*
Bacterial capsule forms a physical barrier between C3b and CR1 interaction	*Streptococcus pneumoniae*
Shown by other microbes	
Proteins mimicking complement regulatory proteins	Vaccinia virus, Herpes simplex virus, Epstein-Barr virus, *Trypanosoma cruzi*, *Candida albicans*

REGULATION OF COMPLEMENT PATHWAYS

Complement system are antigen non-specific; capable of attacking microorganisms as well as host cells. Hence, several regulatory mechanisms have evolved to restrict complement activity only to the designated target cells. There are a series of regulatory proteins, which inactivate various complement components at different stages (Table 13.5).

TABLE 13.5: Regulation of complement system

Regulatory proteins	Pathway affected	Type of protein	Regulatory function
C1 regulator			
C1 inhibitor (C1 Inh, or C1 esterase inhibitor)	Classical only	Soluble	It is a glycoprotein, inhibits the action of C1q by splitting C1qrs into C1rs and C1q. Thus, the whole classical pathway is inhibited.
C3 convertase regulators			
C4b-binding protein (C4bBP)	Classical and lectin	Soluble	▪ It blocks formation of C3 convertase by binding C4b ▪ It acts as cofactor for cleavage of C4b by factor I
CR-1 (Complement-receptor-1)	All three pathways	Membrane bound	Blocks formation of C3 convertase by binding C3b or C4b
MCP (Membrane-cofactor protein)			
Factor H	Alternative only		
DAF (Decay accelerating factor) or CD55	All three pathways	Membrane bound	Accelerates dissociation of C3 convertase
Factor-I	All three pathways	Soluble	Cleaves C4b or C3b by using C4b-binding protein
MAC formation regulators			
S protein	All three pathways	Soluble	Binds to soluble C5b67 and prevents its insertion into cell membrane
Membrane inhibitor of reactive lysis (MIRL or CD59)		Membrane bound	Inhibit MAC formation by blocking C9 binding
Homologous restriction factor		Membrane bound	Inhibit MAC formation by blocking C9 binding

COMPLEMENT DEFICIENCIES

Complement deficiency associated diseases fall into two categories; diseases associated with—(1) complement protein deficiencies and (2) complement regulator protein deficiencies (Table 13.6).

TABLE 13.6: Complement deficiency diseases

Complement deficiencies	Pathway(s) involved	Disease/pathology
Complement protein deficiencies		
C1, C2, C3, C4	C1, C2, C4—Classical pathway C3—Common deficiency	Sytemic lupus erythematosus (SLE), glomerulonephritis and pyogenic infections
Properdin, Factor D	Alternative pathway	*Neisseria* and pyogenic infection
Membrane attack complex (C5-C9)	Common deficiency	Disseminated *Neisseria* infection
Complement regulatory protein deficiencies		
C1 esterase inhibitor	Overactive classical pathway	Hereditary angioneurotic edema
DAF (Decay accelerating factor) and CD59	Deregulated C3 convertase Increased RBC lysis	PNH (Paroxysmal nocturnal hemoglobinurea)
Factor I	Deregulated classical pathway with over consumption of C3	Immune complex disease; recurrent pyogenic infections
Factor H	Deregulated alternative pathway with increased C3 convertase activity	Immune complex disease; pyogenic infection

EXPECTED QUESTIONS

I. Essay:

1. What is complement? Explain in detail about classical complement pathway. List various effector functions of complement.

II. Write short notes on:

1. Alternative complement pathway
2. Lectin complement pathway
3. Various mechanisms of microbial evasion of complement system
4. Complement deficiency diseases

III. Multiple Choice Questions (MCQs):

1. C-3 convertase in alternative complement pathway is:
   a. C14b2a
   b. C3bBb
   c. MBL/MASP-C4b2a
   d. C3b

2. Which of the following acts as an anaphylatoxin?
   a. C3a
   b. C3b
   c. C4b
   d. C2a

3. Endotoxin acts by:
   a. Classical pathway
   b. Lectin pathway
   c. Alternative pathway
   d. None

4. Disseminated *Neisseria* infection is commonly associated with deficiency of:
   a. Properdin
   b. Factor D
   c. C1 inhibitor deficiency
   d. Membrane attack complex (MAC)

Answers

1. b **2.** a **3.** c **4.** d

CHAPTER 14

Structure of Immune System

Chapter Preview

- Lymphoid organs—central and peripheral lymphoid organs
- Lymphoid cells—T cells, B cells and NK cells
- Other cells of immune system
- Major histocompatibility complex
- Cytokines

Immune system comprises of lymphoid organs, cells of immune system (lymphoid cells and other cells) and their soluble products called cytokines (Table 14.1).

CENTRAL LYMPHOID ORGANS

Bone Marrow

Almost all the cells in blood are originated from pluripotent hematopoietic stem cells of bone marrow and the process is called hematopoiesis.

- In early fetal life, hematopoiesis occurs in liver; gradually the stem cells migrate to bone marrow. By birth, the stem cells occupy most of the bone marrow space of large bones.
- As the individual ages, hematopoietic activity in large bones decreases and after puberty hematopoiesis is mostly confined to axial bones such as pelvis, vertebrae, sternum, skull and ribs.

TABLE 14.1: Structure of immune system

- **Lymphoid organs:** Consist of central and peripheral lymphoid organs
  - **Central or primary lymphoid organs** e.g., thymus and bone marrow: They host the development of immune cells (hematopoiesis)
  - **Peripheral or secondary lymphoid organs** e.g., lymph node, spleen, and Mucosa-associated lymphoid tissue (MALT)
- **Lymphoid cells:** Consist of lymphocytes such as T cells, B cells and NK cells
- **Other cells of immune system:** Include phagocytes, such as macrophage and microphages (neutrophil, eosinophil and basophil), dendritic cells, mast cells and platelets
- **Cytokines:** They are the soluble products secreted from various cells of immune system. It Include interleukins, interferons, tumor necrosis factors, colony stimulating factors, etc.

- The progenitor T and B cells originate in bone marrow. Further development of B cells occurs in bone marrow itself, whereas the progenitor T cells migrate to thymus for further proliferation.

Thymus

Thymus is the site of proliferation and maturation of T cells.

Development

Thymus is developed in the embryonic life (third month) from third/fourth pharyngeal pouch. It is highly active at birth, continues to grow for many years, reaches its peak size at puberty, and then it degenerates.

Structure

Thymus has two lobes surrounded by a fibrous capsule. Septa arising from capsule divide thymus into lobules, and each lobule is differentiated into an outer cortex and an inner medulla (Fig. 14.1).

Cortex is densely populated and contains:

- Thymocytes: Lymphocytes of thymus are called as thymocytes. The cortical thymocytes are immature and many in number.
- Cortical epithelial cells and
- Nurse cells (specialized epithelial cells with long membrane extensions that surround many thymocytes).

Medulla is sparsely populated and contains:

- Thymocytes: Medullary thymocytes are relatively more mature and fewer in number
- Medullary epithelial cells
- Interdigitating dendritic cells and
- Hassall's corpuscles: They are concentric layers of degenerating epithelial cells.

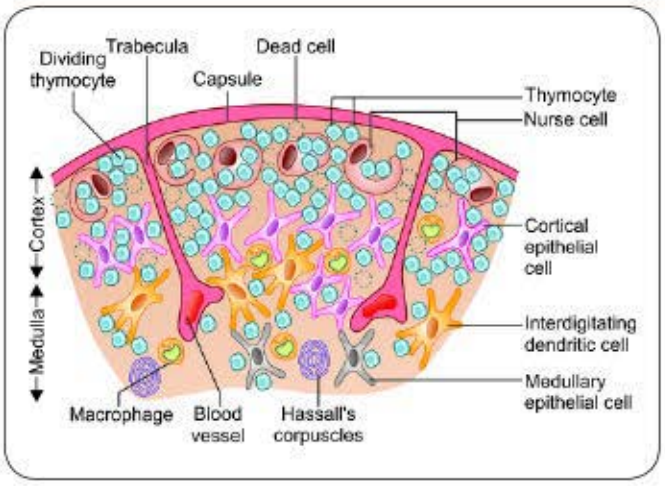

Fig. 14.1: Thymus (cross section of a portion, schematic)

Thymic Hormones

Several thymic hormones such as thymulin, thymopoietin and thymosin are produced from the epithelial cells of thymus. They are believed to attract the precursor T cells (progenitor T cells) from bone marrow.

Maturation of T Cells

The cell-to-cell interaction between thymocytes and thymic stromal cells (including epithelial cells, dendritic cells and macrophages) and the effect of thymic hormones help in maturation of T cells in thymus. (Detail about maturation of T cells is described later in this chapter).

Central Tolerance

One very interesting fact is that only 2–5% of the developing T cells become mature and released out from thymus; remaining T cells are destroyed as they are either not capable of recognizing MHC or are believed to be self-reacting in nature.

- Destruction of such self-reacting T cells prevents development of autoimmunity (immune response against self-antigens).
- Such tolerance to self-antigens mediated by thymus that occurs in embryonic life is called as central tolerance.

Defect in Thymus

Any defect in thymus leads to defect in maturation of T lymphocytes that in turn results in severe life-threatening cell-mediated immunodeficiency disorders.

- **DiGeorge syndrome:** It is an immunodeficiency disorder in man, characterized by congenital aplasia of thymus (Chapter 18).
- **Nude mice:** Mice with congenital absence of thymus are called as nude mice.

PERIPHERAL LYMPHOID ORGANS

Lymph Node

Lymph nodes are small bean-shaped organs; they occur in clusters or in chains, distributed along the length of lymphatic vessels. They act as physiological barriers; filter the microbial antigens carried to lymph node by activating the T and B cells.

Structure

Lymph node is divided into three parts—cortex, medulla (both are B cell areas) and paracortex (T cell area). It bears the lymphatic and blood vessels. Cortex is surrounded by a capsule and intervened by trabeculae (Fig. 14.2).

- **Cortex:** It contains lymphoid follicles that are composed of mainly B cells and few special type of dendritic cells (called follicular dendritic cells). Lymphoid follicles are mainly of two types.
  1. **Primary lymphoid follicles:** They are found before the antigenic stimulus. They are smaller in size and mainly contain the resting B cells.
  2. **Secondary lymphoid follicles:** Following contact with an antigen, the resting B cells start dividing and become activated. The activated B cells differentiate rapidly in to plasma cells (which produce antibodies) and memory B cells (which become activated on subsequent antigenic exposure). Follicles become larger in size and called secondary lymphoid follicles. It has two areas:
     - The central area called **germinal center;** contains dividing B cells of various stages. It has two zones—light and dark zones. It is the site where activation of B cells takes place (described in detail in Chapter 15).
     - The peripheral zone called **mantle area;** contains activated B cells.
     - **Paracortical area:** It is present in between cortex and medulla. It is the **T cell area** of lymph node; rich in plenty of naive T cells. In addition, it

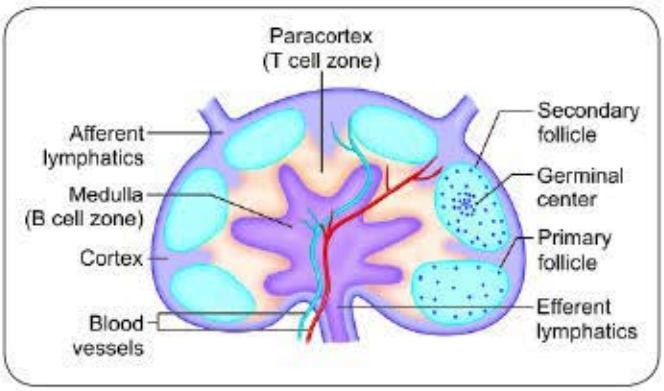

Fig. 14.2: Lymph node

also contains macrophages and interdigitating dendritic cells, which trap the antigens and present to T cells.

3. **Medulla:** It is the innermost area of lymph node, rich in B-lymphocytes; mainly plasma cells.

Spleen

Spleen is the largest secondary lymphoid organ. It acts as physiological barrier similar to lymph node in clearing the microbial antigens through the stimulation of T and B cells.

Structure

Spleen is situated below the diaphragm on left side of the abdomen. Adult spleen measures about 5-inch in length and weighs 150 g. It is divided into two compartments—central white pulp and outer red pulp, surrounded by capsule and intervened by trabeculae (Fig. 14.3).

1. **White pulp:** It is the central densely populated area, which contains T cells and B cells. It has two parts:
   i. **Periarteriolar lymphoid sheath (PALS):** It is T cell area, rich in T cells; surrounds the branches of the splenic artery.
   ii. **Marginal zone:** It is located peripheral to the PALS and is populated by B cell lymphoid follicles (primary and secondary) and macrophages.
2. **Red pulp:** It is the area that surrounds the sinusoids. It is filled with red blood cells (RBCs). The older and defective RBCs are destroyed here.

Defect in Spleen

As spleen is the site of destruction of most of the microbes, functional or structural abnormalities of spleen or splenectomy, especially in children, often leads to an increased incidence of bacterial sepsis caused primarily by capsulated bacteria such as *Streptococcus pneumoniae, Neisseria meningitidis,* and *Haemophilus influenzae.*

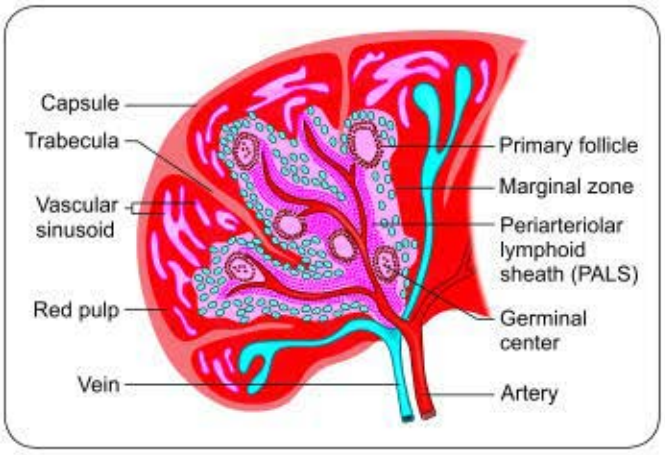

Fig. 14.3: Spleen (cross-section showing red pulp and white pulp area)

Mucosa-associated Lymphoid Tissue (MALT)

The mucous membranes lining the intestine, respiratory, and urogenital tract (total surface area of about 400 m^2) are the major sites of entry for most pathogens. Hence, defense mechanisms are needed in the mucosal sites to prevent the microbial entry.

- Group of lymphoid tissues lining these mucosal sites are collectively known as mucosa-associated lymphoid tissue (MALT).
- Structurally, MALT may be arranged in two types:
  1. Loose clusters of lymphoid cells (usually found in the lamina propria of intestinal villi).
  2. Lymphoid tissues arranged as organized structures such as tonsils, appendix and Peyer's patches).

MALT in Intestinal Mucosa

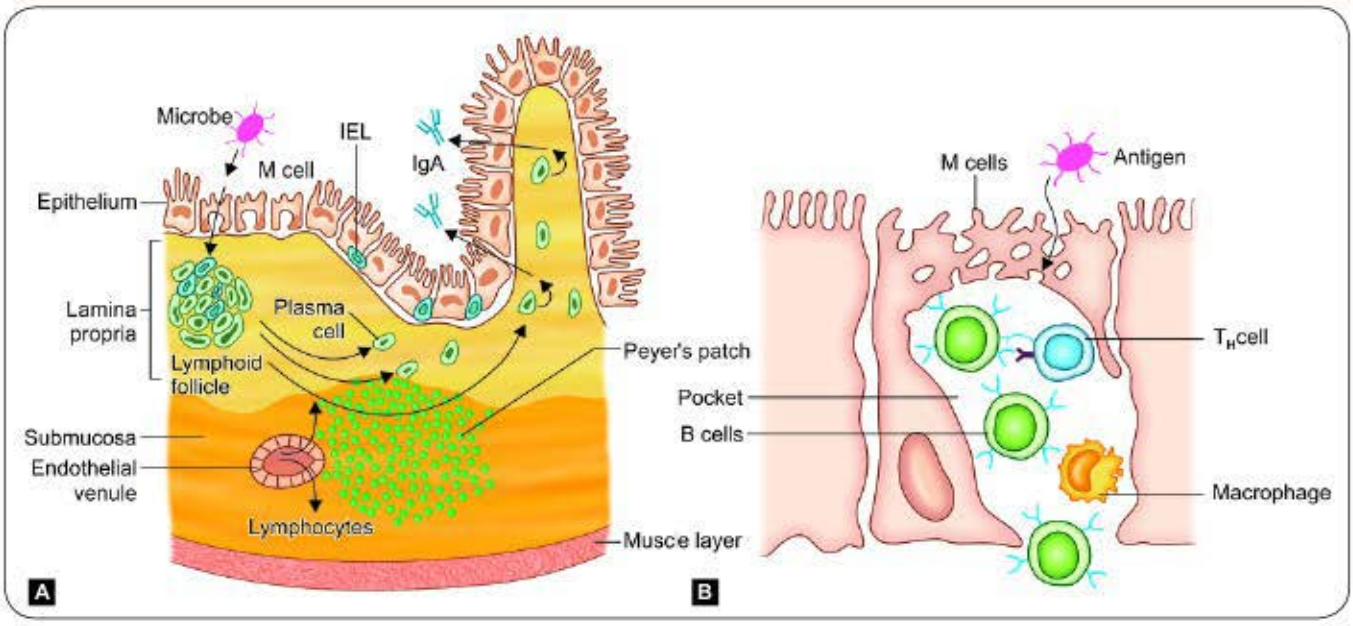
Lymphoid tissues lining the intestinal mucosa are the best studied MALT. They are present in different layers of intestinal wall.

- **Submucosa** contains Peyer's patches. Peyer's patch is a nodule of 30–40 lymphoid follicles (both primary and secondary follicles similar to that of lymph node).
- **Lamina propria** contains loose clusters of lymphocytes (B cells, plasma cells, T helper cells) and macrophages.
- **Epithelial layer** contains few specialized lymphocytes called intraepithelial lymphocytes (IELs) and modified epithelial cells (called M cells).
  - **Intraepithelial lymphocytes (IELs)** are the γδ T cells. The actual function of such T cells is not known, they may encounter the lipid antigens that enter through the intestinal mucosa.
  - **M cells:** Described in the box below.
  - **Secretory IgA:** These are the dimeric IgA antibodies that are present in the submucosa as well as in the lining epithelium. They prevent the microbial entry at the mucosal sites (local immunity).

M Cells

They are specialized flattened epithelial cells that do not have microvilli; instead they bear deep invaginations or pockets in the basolateral side that contain B cells, T cells and macrophages (Fig. 14.4A).

- M cells act as the portal of entry of a number of microbes such as *Salmonella, Shigella, Vibrio* and poliovirus.
- Invading microbes are taken-up by M cells (by endocytosis), then transported in a vesicle and are delivered to the basolateral pockets.
- T cells, B cells and macrophages in the underlying lymphoid follicles are activated following contact with the microbe.
- B lymphocytes in MALT once activated at a site by antigenic exposure, migrate to other parts of the intestine, secrete the dimeric IgA, and thus extend the local immunity (Fig. 14.4B).



Figs 14.4A and B: A. MALT; **B.** Structure of M cell

Cutaneous-associated Lymphoid Tissue

Similar to MALT, skin also contains a few loose lymphocytes and specialized antigen presenting cells in epidermis called **Langerhans cells**.

LYMPHOID CELLS

Cells of immune system comprise of lymphoid cells or lymphocytes and other cells such as phagocytes (e.g. macrophages and granulocytes), etc.

Lymphocytes are the major components of cells of immune system. There are approximately 10^{11} lymphocytes in the body, accounting for 20–40% of the total white blood cells (WBCs) in blood and 99% of the cells in the lymph (Table 14.2).

CD molecules

Cluster of differentiation (CD) molecules are cell surface markers useful for the identification of cells of immune system. They have numerous functions, often act as surface receptors or some CD proteins may help in cell adhesion. As of 2015, CD molecules for humans are numbered up to 364.

TABLE 14.2: Distribution of lymphocytes (%) in organs/blood

Tissues	T cell	B cell	NK cell
Bone marrow	5–10	80-90	5–10
Thymus	99	<1	<1
Lymph node	70–80	20–30	<1
Spleen	30–40	50–60	1–5
Peripheral blood	70–80	10–15	10–15

TYPES OF LYMPHOCYTES

Based on function and cell membrane structure, lymphocytes can be of three types—T lymphocytes, B lymphocytes and natural killer (NK) cells.

The T and B lymphocytes can also be classified into naive lymphocytes and lymphoblasts.

Naive Lymphocytes

They are resting B and T lymphocytes that have not interacted with any antigen (unprimed lymphocytes).

- They are also known as small lymphocytes, as they are small in size (6 µm); having thin rim of cytoplasm, larger nucleus with dense chromatin; fewer mitochondria, ribosomes, and lysosomes.
- They generally have a short-life span (1–3 months).

Lymphoblasts

When the naive cells interact with antigen in the presence of certain cytokines (e.g. interleukin-7), become activated and transform into lymphoblasts, which eventually differentiate into effector cells or memory cells.

- **Effector cells** function in various ways to eliminate antigen.
  - They have short-life span (few days to few weeks).
  - They are large lymphocytes (15 µm in size), having wider rim of cytoplasm with more organelles.

TABLE 14.3: Differences between naive, effector and memory cells

	Naive cell	Effector cell	Memory cell
Location (present mostly in)	Secondary lymphoid organs	Inflamed tissues and mucosal surfaces	Both the locations of naive and effector cell
Cell cycle	Dormant (G0 phase)	Active	Dormant (G0 phase)
Morphology	Small lymphocyte	Large lymphocyte	Small lymphocyte
Life span	Short	Short	Long
Function	Transforms to effector cell on primary exposure to antigen, occurs slow due to lag period	Eliminate antigen	Transforms to effector cell on secondary exposure to antigen, occurs fast without lag period
Surface markers			
CD127 (IL-7R)	High	Low	High
CD45 isoform	CD45RA	CD45RO	CD45RO
CD25 (IL-2R α) on T cells	No	Yes	Yes
CD27 on B cells	No	Yes	Yes
B cells producing Ig types and their affinity	IgM and IgD Low affinity	IgG, IgA, IgE High affinity	IgG, IgA, IgE High affinity

- Antibody producing plasma cells are classical example of effector B cells; whereas effector T cells include helper T cells and cytotoxic T cells.

- **Memory cells:** They remain dormant like naive cells but are capable of transforming into effector cells rapidly on subsequent antigenic challenge.
  - They have a longer life span; providing long-term immunity against many pathogens.
  - They look like small lymphocytes but can be distinguished from naive cells by the presence or absence of certain surface markers (Table 14.3).

T LYMPHOCYTES

T cells constitute 70–80% of blood lymphocytes. Unlike B cells, they do not have microvilli on their surface. They bear specialized surface receptors called T cell receptors (TCR).

T Cell Receptor

The T cell receptors (TCR) of T cells are equivalent to the surface immunoglobulins (B cell receptors) of the B cells. Their main function is antigen recognition. Unlike B cell receptor which binds to antigen directly, TCR does not recognize antigen by itself. It can only respond to an antigen which is processed and presented by the antigen presenting cells, such as macrophages.

TCR–CD3 Complex

Most T cell receptors (95%) comprise of two chains (α and β) which in turn have three regions—extracellular domain, transmembrane domain, and cytoplasmic tail. The extracellular domain of each polypeptide chain has 2 regions (variable and constant region). Five percent of TCRs do not have α/β chains, instead they bear γ/δ chains. TCR is active only when both the chains (α and β) complex with CD3 molecule (Fig. 14.5).

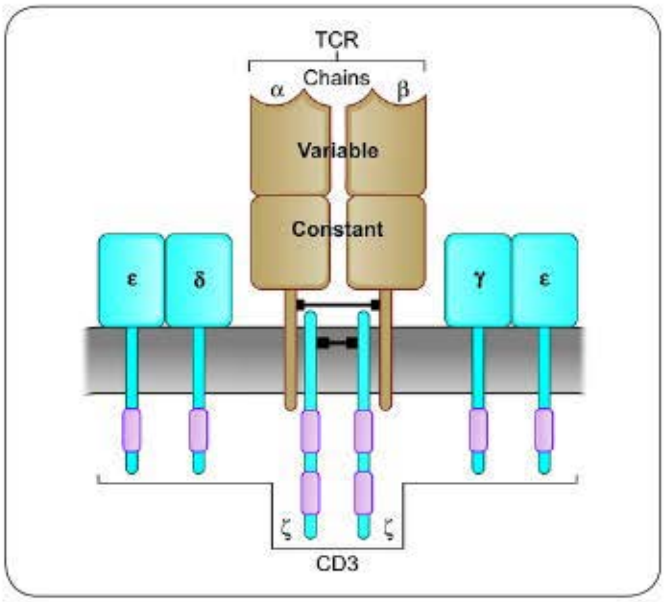


Fig. 14.5: Structure of T cell receptor

- The **variable region** of α and β chains of TCR bind to the presented antigens. They are polymorphic in nature. Rearrangement of α and β genes during T cell development can produce large number of different

combinations of TCRs. Each TCR is capable of recognizing a particular epitope of an antigen.

- The **CD3 complex** consists of three pairs of polypeptide chains—ξξ (zeta-homodimer), δε (delta-epsilon heterodimer) and γε (gamma-epsilon heterodimer).
- Following binding of antigen to α and β chains of TCR, a signal is generated that is transmitted through the CD3 complex leading to activation of T cells.

T Cell Development

The major events of T cell maturation take place in thymus, in contrast to bone marrow for B cells.

- The progenitor T cells are originated from the bone marrow (or liver in fetal life) and then migrate to thymus through bloodstream.
- Developing T cells in the thymus (collectively called as thymocytes) pass through series of stages that are marked by characteristic changes in their cell surface markers.
- Most of the development events take place in the cortex of thymus, under the influence of thymic stromal cells which secrete thymic hormones and lymphopoietic growth factor IL-7.

The sequence of events of T cell development is as follows (Fig. 14.6):

- **Double negative (DN) T cells:** T cell precursors after entering into the thymus transform into double negative T cells ($CD4^-$ $CD8^-$). These cells are so called because, they do not express the surface markers of mature T cells, i.e. CD4 (marker of helper T cells) and CD8 (marker of cytotoxic T cells). They are further subdivided into four subsets. DN1 T cells are developed first, then → DN2 → DN3 → DN4 T cells.
  - As the DN1 cells develop into DN2 cells, genes for γ, δ and β chains of TCR begin to rearrange and the CD3 molecules are then expressed.
  - At the late DN2 stage, T cell precursors fully commit to any one of the T cell lineages:
    - Five percent carrying TCR γδ receptors develop into mature γδ T cells and
    - The remaining (95%) of the cells develop further to DN3 T cells.
  - As the DN3 cells differentiate into DN4 cells, the β chain of TCR is complexed with CD3 molecules to form pre-TCR.
  - In DN4 stage, rearrangement of α chain takes place and then it combines with β chain to form complete αβ TCR. The αβ T cells develop further to express CD4 and CD8 molecules and transform to double positive (DP) T cells.
- **Double positive (DP) T cells ($CD4^+$/$CD8^+$):** They are immature T cells, carrying both CD4 and CD8 molecules on their surface. They further undergo the one of the following fate:
  - **Positive selection:** The 5% of DP T cells, whose αβ receptors are capable of recognizing their MHC molecules are positively selected. This results in MHC restriction.
  - **Death by neglect:** Majority of DP cells (95%) fail positive selection because they do not specifically recognize their MHC molecules.
  - **Negative selection:** The survived cells that undergo positive selection (5%) are MHC restricted. However, some of these surviving cells (2–5%) react to the self antigens and therefore, they are selected to be killed by apoptosis and removed (negatively selection).
  - The remaining double positive T cells (2–5%) having αβ type TCR selectively shut off the expression of either CD4 or CD8 molecules and eventually

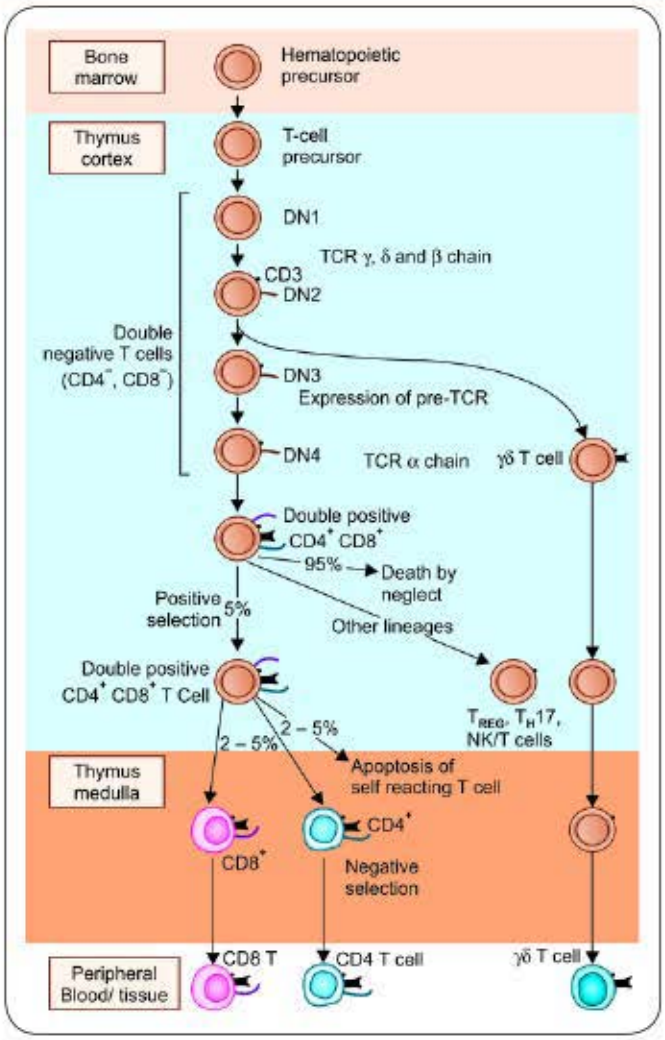

Fig. 14.6: T cell development

become single positive mature T cells ($CD4^+/CD8^-$ or $CD4^-/CD8^+$).

- **Mature T cells** (e.g. $CD4^+$ helper T cells and $CD8^+$ cytotoxic T cells) acquire thymus specific antigens and then are released into the circulation and migrate to the peripheral lymphoid organs where they respond to the antigenic stimulus.

Types of T Cells

Effector T Cells

There are two types of effector T cells—$CD4^+$ helper T cells and $CD8^+$ cytotoxic T cell.

- **Helper T cells:** Helper T cells (T_H) possess CD4 molecules as surface receptors. They recognize the antigenic peptides that are processed by antigen presenting cells and presented along with MHC-II molecules (major histocompatibility complex).
  - Following antigenic stimulus, the helper T cells differentiate into either of the two types of cells— T_H1 and T_H2 subset; each secrete specific cytokines which modulate the cellular and humoral immune responses respectively (for detail, refer Chapter 15).
  - **T_H17 cells:** Recently a third subset of T helper cells called T_H17 cell, has been discovered and characterized. It produces IL-17 and IL-22, and is primarily involved in recruiting neutrophils which in turn kill the microbes as well as induce inflammation. They contribute to the pathogenesis of many autoimmune inflammatory diseases such as psoriasis, inflammatory bowel disease, rheumatoid arthritis, and multiple sclerosis.
- **Cytotoxic T cells:** In contrast to T_H cells, cytotoxic T cells (T_C) possess CD8 molecules and recognize the intracellular antigens (e.g. viral antigens or tumor antigens) that are processed by any nucleated cells and presented along with MHC-I. In general, T_C cells are involved in destruction of virus infected cells and tumor cells (for detail, refer Chapter 15).

Rare Subtypes of T Cells

- **Regulatory T cells (T_{REG} cells):** The T_{REG} cells (formerly known as suppressor T cells) are a subpopulation of T cells which regulate the immune system.
  - They provide tolerance to self-antigens (known as peripheral tolerance), and thus prevent the development of autoimmune disease.
  - Surface markers: T_{REG} cells possess surface markers such as CD4, CD25 and Foxp3 (a forkhead family transcription factor).
  - Deficiency of Foxp 3 receptors leads to a severe form of autoimmune disease known as **I**mmune dysregulation, **P**olyendocrinopathy, **E**nteropathy **X**-linked (**IPEX**) **syndrome**.
- **γδ T cells:** γδ T cells represent a small subset of T cells (5%) that possess a distinct TCR composed of γ and δ chains; instead of α/β chains. They lack both CD4 and CD8 molecules.
  - They differ from the conventional α/β T cells by the fact that they do not require antigen processing and MHC presentation of peptides.
  - They are part of innate immunity as the γδ receptors exhibit limited diversity for the antigen.
  - They are usually found in the gut mucosa, within a population of lymphocytes known as intraepithelial lymphocytes (IELs).
  - The function of γδ T cells is not known, they may encounter the lipid antigens that enter through the intestinal mucosa.

B LYMPHOCYTES

B lymphocytes are the mediators of humoral immunity; constitutes 10–15% of blood lymphocytes. They are named after their site of maturation (**b**ursa of Fabricius in birds and **b**one marrow in humans and other mammals). B cells proliferate through various stages, first in bone marrow, then in peripheral lymphoid organs (Fig. 14.7).

Development of B Cells in Bone Marrow

Initial stages of B cell proliferation occur in bone marrow; independent of exposure to antigen.

Pro-B Cells (Progenitor B Cells)

They are the earliest bone marrow cells of B cell lineage. They do not produce immunoglobulin (Ig) but express a heterodimer Igα/Igβ that forms a part of the B cell receptor (BCR) in future.

Pre-B Cells (Precursor B Cells)

Pro-B cells differentiate into pre-B cells by undergoing Ig heavy chain genes rearrangement. This stage is characterized by translation of heavy chain genes.

- **μ heavy chain** is synthesized first and then it accumulates in cytoplasm.
- **Surrogate light chain:** Pre B cells do not form light chains; but synthesize some similar but smaller peptides, which are not true light chains. They are called surrogate light chain.
- **Pre-BCR synthesis:** μ chain and surrogate light chains complex with hetero dimer Igα/Igβ to form pre-B cell receptor.
- Pre-BCR always allows the expression of only one out of the two alleles coding for an Ig chain by inhibiting the other allele. This phenomenon is called as **allelic**

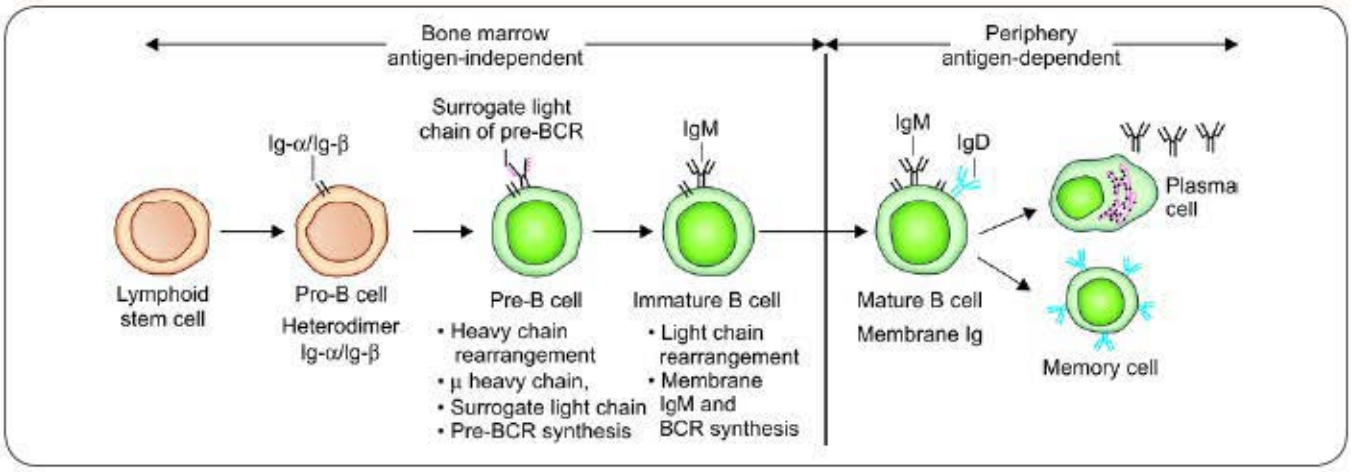

Fig. 14.7: B lymphocyte development

exclusion by which the clonal specificity of B cells is maintained.

Immature B Cells

Pre-B cells proliferate into immature B cells which are characterized by the following properties:

- **Light chain genes rearrangement** takes place and following which the light chains are expressed. By allelic exclusion, only one type of light chain (either kappa or lambda) is allowed to express.
- **Membrane IgM:** Heavy chain μ and its light chain join to form complete IgM molecule, which is complexed with heterodimer Igα/Igβ on the B cell surface to form B cell receptor (Fig. 14.8).
- **Tolerance:** Some of the immature B cells are capable of recognizing self-antigens. Tolerance to those B cells are essential for prevention of autoimmunity. Following contact with a self-antigen, the tolerance is developed either by:
  - **Receptor editing:** A process by which the Ig genes coding light chains are rearranged so that a different (edited) B cell receptor is produced which no longer recognizes the self-antigen or
  - **Negative selection:** By apoptosis of self-reacting immature B cells in spleen.

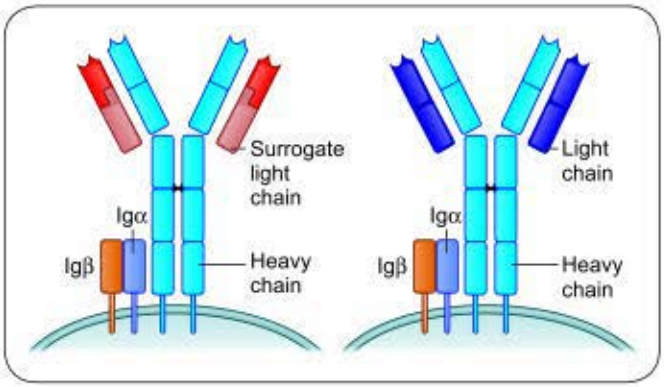

Fig. 14.8: Structure of B cell receptor

Development of B Cells in Peripheral Lymphoid Organs

Immature B cells migrate from bone marrow to peripheral lymphoid organs (lymph node and spleen) where they transform into mature B cells following contact with appropriate antigen.

Mature or Naive B Cells

Most mature B cells (95%) belong to the follicular B cell type and produce surface receptor IgD in addition to IgM. They play an important role in humoral immune response (detail is described in Chapter 15).

- Following antigenic stimulus, the mature B cells transform into activated B cells (lymphoblasts) which further differentiate into either effector B cells, i.e. plasma cells (majority) or memory B cells.
- **Plasma cells** (antibody secreting cells): They are oval, large (15 μm size), with an eccentrically oval nucleus containing large blocks of peripheral chromatin (cartwheel appearance) and the cytoplasm containing abundant organelles. They have a short life span of two or three days.

However, there are few rare mature B cell types such as B-1 cell and marginal zone B cells which have limited diversity and are components of innate immunity.

- **B-1 cells:** They are found mostly in the peritoneal cavity, coated by surface markers IgM (natural antibodies) and CD5 molecules, but lack IgD.

TABLE 14.4: Differences between T cell and B cell

Property	T cell	B cell
Origin	Bone marrow	Bone marrow
Maturation	Thymus	Bone marrow
Peripheral blood	70–80% of total lymphocytes	10–15% of total lymphocytes
Antigen recognition receptors	T cell receptors complexed with CD3	B cell receptor-surface IgM or IgD complexed with Igα/Igβ
CD markers	CD 3, 4, 8	CD19, 21, 24
Thymus specific Ag	Present	Absent
Microvilli on the surface	Absent	Present

- **Marginal-zone B cells:** They are present at the edges of lymphoid follicles of spleen and are produced in response to the polysaccharide antigens.

B cells are the main components of humoral immunity; produce five classes of antibodies, which in turn have various biological functions (described in Chapter 15).

Differences between T cell and B cell are given in Table 14.4.

NATURAL KILLER CELLS

NK cells are large granular lymphocytes that constitute 10–15% of peripheral blood lymphocytes. They are derived from a separate lymphoid lineage. Similar to cytotoxic T cells, NK cells also are involved in destruction of virus infected cells and tumor cells (described in Chapter 15).

OTHER CELLS OF IMMUNE SYSTEM

Macrophage

Macrophages were first described by Russian scientist Metchnikoff (1883) who suggested that the monocyte-macrophage system plays a vital role in host defense by performing two important functions—phagocytosis and antigen presentation.

Monocytes/macrophages originate from bone marrow, from a separate lineage, i.e. from the granulocyte-monocyte progenitor cells.

Monocytes: They are present in blood; they are the largest blood cells measuring 12–20 μm size. They do not divide and have an average transit time of 8 hours in blood; then they migrate to tissues.

Macrophages: When monocytes migrate to tissues, they transform into macrophages (Fig. 14.9). Macrophages differ from monocytes in the following:

- 5–10 folds larger than monocytes

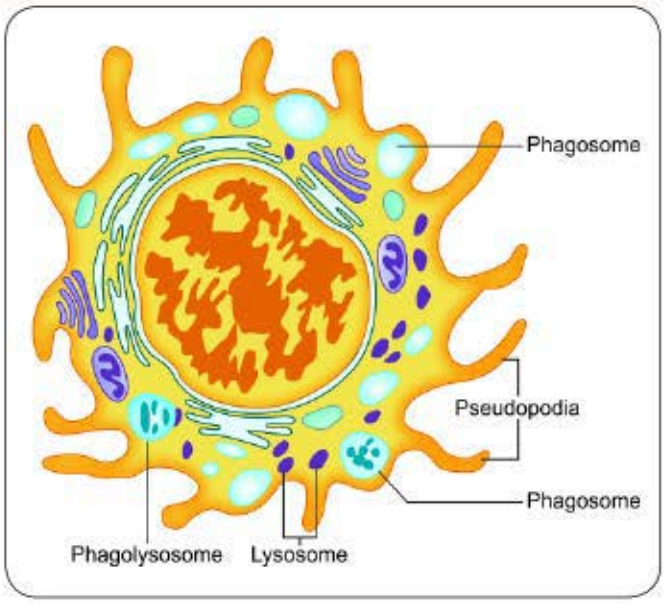

Fig. 14.9: Macrophage

- Contain more lysozymes and cell organelles
- Produce more lytic enzymes and cytokines
- Possess greater phagocytic activity
- Have a longer life in tissues (months to years).

Most macrophages are motile, travel by amoeboid movement throughout the tissues and are called as free or wandering macrophages. While, some reside in particular tissue, become non-motile and are called fixed macrophages. Macrophages in various tissues are designated by different names (Table 14.5).

Secretory Products of Macrophages

Activated macrophages in turn produce a number of secretory products which mediate various functions (Table 14.6).

TABLE 14.5: Types of macrophages

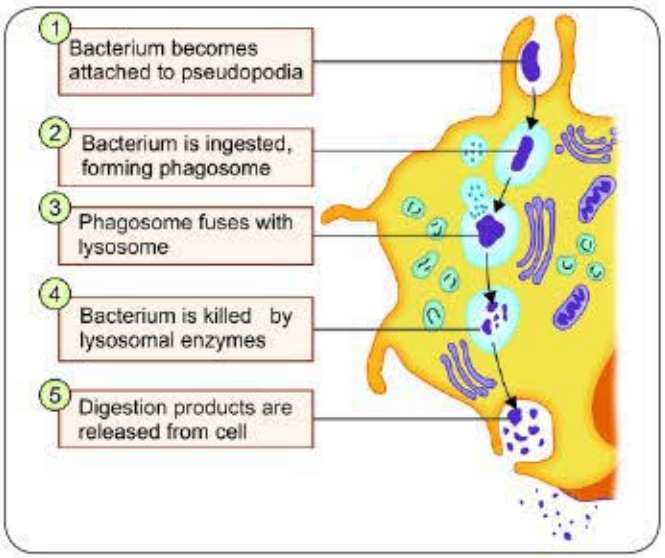
Body sites	Macrophage designation
Peripheral blood	Monocytes
Tissues	Macrophages
Liver	Kupffer cells
Brain	Microglial cells
Kidney	Mesangial cells
Lungs	Alveolar macrophages
Bone	Osteoclasts
Inflammation site	Epithelioid cells, multinucleated cell (Langhans giant cells)
Connective tissues	Histiocytes
Placenta	Hofbauer cell
Lymphoid follicle	Tingible body macrophage

TABLE 14.6: Secretory products of activated macrophages

Secretory Products	Examples
Enzymes	Lysozyme, acid hydrolases, elastases, Phosphatases, lipases, collagenases
Free radicals	**Reactive oxygen intermediates** ▪ Superoxide anion (O_2^-) ▪ Hydroxyl radicals (OH) ▪ Hydrogen peroxide (H_2O_2) ▪ Hypochlorite anion(ClO^-) **Reactive nitrogen intermediates** ▪ Nitric oxide (NO) ▪ Nitrogen dioxide (NO_2) ▪ Nitrous acid (HNO_2)
Cytokines	Interferon α,β Interleukins (IL-1, IL-6, IL-8, IL-12) Tumor necrosis factor- α (TNF- α)
Growth factors	Colony-stimulating factors (CSF) Platelet-derived growth factor (PDGF) Platelet-activating factor (PAF) Transforming growth factor β (TGF-β)
Coagulation factors	Factor V, VII, IX, X Prothrombin
Complement factors	C5, C8 properdin, factor B, D, I

Functions of Macrophage

- **Phagocytosis:** Macrophages are the principle cells involved in phagocytosis. Macrophages from various tissues are together called as the mononuclear phagocyte system (or previously known as the reticuloendothelial system). They also remove old dying cells from the body. The steps involved in phagocytosis are as follows (Fig. 14.10).



1 Bacterium becomes attached to pseudopodia
2 Bacterium is ingested, forming phagosome
3 Phagosome fuses with lysosome
4 Bacterium is killed by lysosomal enzymes
5 Digestion products are released from cell

Fig. 14.10: Mechanism of phagocytosis

  - **Recognition:** Attachment of the microbe to the receptors present on the surface of macrophage, such as toll like receptors or immunoglobulin G (IgG).
  - **Engulfment:** Microbe is ingested with subsequent formation of a phagocytic vacuole (phagosome).
  - **Fusion** of lysosome with phagosome to form phagolysosome.
  - **Killing or degradation** of the ingested microbes which is accomplished largely by both:
    - Oxygen independent killing—degradation by lysosomal enzymes.
    - Oxygen dependent killing by generating free radicals (Table 14.6).
- **Antigen presentation:** Macrophages also promote adaptive immunity, by acting as antigen presenting cells (APCs). Macrophages capture the antigen, process into smaller antigenic peptides and present the antigenic peptides along with the MHC class II molecules to the helper T cells; thus facilitating helper T cell activation.
- **Activated macrophages:** On exposure to certain cytokines such as interferon-γ, macrophages become activated. The activated macrophages have greater phagocytic ability and produce many cytokines that act against intracellular bacteria, virus infected cells and tumor cells. They also express higher level of MHC class II, hence can act as efficient APCs.
- **Secretory products** of macrophages have various biological functions:
  - Interleukin 1 (IL-1): It promotes inflammatory responses, fever, and activate helper T cells.
  - IL-6 and TNF-α: It promote innate immunity, (inflammation and fever) and eliminate the pathogens.
  - Interferon α and β: They have antiviral activity.
  - TNF-α: It lyses the tumor cells (antitumor activity)
  - Growth factors, such as CSF (colony stimulating factor)—promote hematopoiesis.
  - Following tissue injury, various mediators are secreted from macrophage; which help in tissue repair and scar formation.

Dendritic Cells

Dendritic cells are specialized antigen presenting cells of immune system (Fig. 14.11).

- **Naming:** They possess long membranous cytoplasmic extensions resembling dendrites of neurons; hence, they are named as dendritic cells.
- **Origin:** Dendritic cells originate from bone marrow, but the pathway is uncertain. They either develop as a separate lineage from stem cells or may originate from the macrophage lineage.

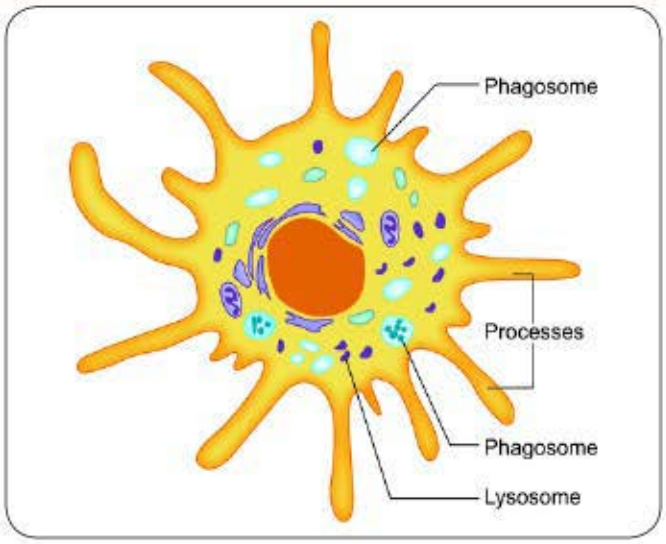


Fig. 14.11: Dendritic cell

TABLE 14.7: Distribution and functions of dendritic cells

Types of dendritic cells	Site	Function
Langerhans cells*	Skin and mucosa	Antigen presentation, express high MHC-II and B7 molecules
Interstitial dendritic cells	Organs (lungs, liver, spleen, etc.)	
Interdigitating dendritic cells	Thymus	
Circulating dendritic cells	Blood and lymph	
Follicular dendritic cells	Lymph nodes	▪ B cells maturation, and differentiation ▪ MHC-II and B7 molecules absent ▪ Coated with Ag-Ab complex

*Langerhans cell is a dendritic cell; whereas Langhans giant cell is a macrophage

- **Types:** Dendritic cells are widely distributed; present in various tissues (Table 14.7).
- **Function:** Dendritic cells are nonphagocytic in nature. They are the most efficient antigen presenting cells (APCs); their main function is to capture, process and present the antigenic peptides on their cell surface to the helper T cells.
  - They carry high level of MHC class II and co-stimulatory B7 molecules.
  - They act as messengers between the innate and the adaptive immune systems.
- **Follicular dendritic cells:** They are present in lymphoid follicles. They differ from other dendritic cells by the fact that they recognize antigen-antibody complex rather than antigen alone. They do not act as APCs and do not express MHC class II or B7 molecules (for detail see Chapter 15).

Granulocytic Cells

Granulocytes (e.g. neutrophils, eosinophils and basophils) are a category of white blood cells, characterized by the presence of granules in their cytoplasm. They differ from each other by cell morphology and cytoplasmic staining and function.

Neutrophils

They have a multilobed nucleus and a granulated cytoplasm that stains with both acid and basic dyes. It is often called a polymorphonuclear leukocyte (PMN) because of its multilobed nucleus.

- Their cytoplasm is heavily granular; contains several granules such as myeloperoxidase, lysozyme, defensins, elastase, gelatinase, etc.
- Neutrophils constitute 50%–70% of the circulating WBCs. However, the level is greatly increased in presence of infection under the influence of certain cytokines, such as IL-8.
- They are the principal phagocytes of innate immunity; the mechanism of microbial killing is similar to that of macrophages, i.e. both by oxygen dependent and independent mechanisms.

Eosinophils

They have a bilobed nucleus and a granular cytoplasm that stains red with the acid dye eosin.

- They are also phagocytic, constitute only 1–3% of total leukocytes, but the number is greatly increased in certain allergic conditions and helminthic infections.
- Interleukin-5 is believed to be the eosinophil chemotactic factor.

Basophils

They are nonphagocytic granulocytes that contain several secreting granules. They have a lobed nucleus and heavily granulated cytoplasm that stains with the basic dye, methylene blue. They resemble mast cells in their function. Granules are rich in histamine and other mediators that play a major role in certain allergic responses.

Mast Cells

Mast cells are present in various body sites, such as skin, connective tissues of various organs, and mucosa (respiratory and intestinal). Like circulating basophils, mast cells also contain cytoplasmic granules rich in histamine and other active substances and play an important role in the development of certain allergic (type I hypersensitivity) reactions.

MAJOR HISTOCOMPATIBILITY COMPLEX

The major histocompatibility complex (MHC) is a group of genes coding for a set of host cell surface molecules that bind to peptide fragments derived from pathogens and display them on the host cell surface for recognition by the appropriate T-cells.

- These are present in almost all the human cells, but first discovered on the surface of leukocytes; hence in humans, the MHC coded proteins are also called as human leukocyte antigens (HLA).
- MHC molecules serve as a unique identification marker for every individual as the genetic sequence of MHC genes is different for every individual.
- Following transplantation of a graft, the recipient mounts an immune response against the graft's MHC molecule and vice versa. Greater the difference of the MHC gene sequence between the graft and the recipient, greater is the immune response and greater is the rejection of the graft.
- The acceptance or rejection of the graft is directly dependent on the MHC molecules of the graft and the recipient. As the MHC molecules determine the compatibility between the graft and host tissues, they are named as **histocompatibility antigens**.

MHC GENES (HLA COMPLEX) AND THEIR PRODUCTS

In humans, HLA complex coding for MHC proteins are located in **short arm of chromosome-6**. The HLA complex extends over 4000 kbp length covering >100 genes. The genes are clustered in three regions named as MHC region-I, II and III (Fig. 14.12).

MHC Region-I

It is about 2000 kbp in length, comprises of three class I genes called HLA-A, HLA-B and HLA-C genes which code for HLA-A, HLA-B and HLA-C proteins respectively, each one is capable of forming the α-chain of MHC class I molecules.

- MHC-I proteins are located on the surface of all nucleated cells (except sperm cells) and platelets. They are absent in RBCs.
- They present the peptide antigen to CD8 T cells.

MHC Region-II

It spans over 1000 kbp length; comprises of three regions—DP, DQ and DR genes encoding DP, DQ and DR proteins respectively, each one is capable of forming the α and β-chain of MHC class II molecules. In addition, MHC II region also contain certain other non-classical genes, such as DO, DM, LMP and TAP (transporter associated with antigen processing) that help in antigen processing and presentation.

- MHC-II proteins are located on the surface of antigen presenting cells.
- They present the peptide antigen to CD4 T cells.

MHC Region-III

It is also 1000 kbp in length. It is not involved in antigen presentation, instead it carries genes that code for complement factors (C2, C4, C3 convertase, factor B and properdin), heat shock protein (HSP) and tumor necrosis factor (TNF-α and β) and steroid 21-hydroxylases.

STRUCTURE OF MHC MOLECULE (FIG. 14.13)

MHC Class I Molecule

It is composed of α chain (glycoprotein, 45kDa) coded by HLA class I genes and β2 *microglobulin* (non-glycosylated

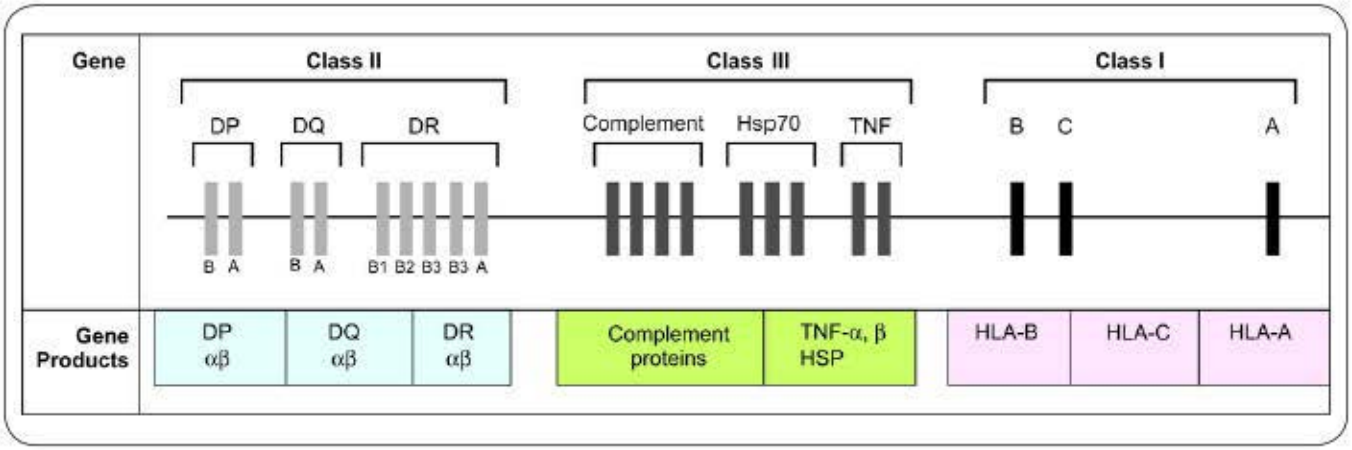

Fig. 14.12: Structure of human MHC complex

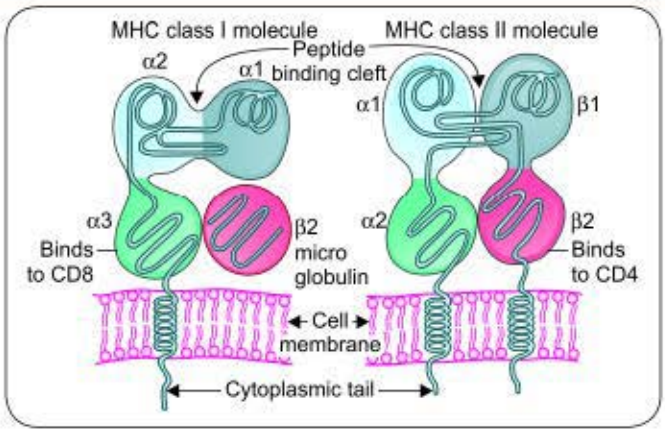

Fig. 14.13: Structure of MHC molecules

12 kDa protein, encoded by a non MHC gene from chromosome 15).

- The α chain is folded further and organized into three extracellular globular domains—α1, α2 and α3 (each containing 90 amino acids) and a cytoplasmic tail.
- The association of β2 microglobulin with α chain is necessary for the expression of MHC I molecules on to the cell surface. In **Daudi cells** (a type of human B cell tumor cell which are not able to produce β2 microglobulin), it is observed that they synthesize MHC-I but do not express them on cell surface.

Role of MHC Class I Molecules

- The antigen peptide groove of class I MHC molecule (i.e. the site, where the antigen peptide binds) is formed by the cleft between α1 and α2 domains.
- The α3 domain binds to CD8 molecule present on cytotoxic T cells during antigen presentation.

MHC Class II Molecule

It comprises of one α chain (33 kDa) and one β chain (28 kDa). The α and β chains in turn consist of two domains each—α1 and α2 and β1 and β2, respectively and cytoplasmic tails.

- The antigen peptide groove is formed by the cleft between α1 and β1 domains.
- The β2 domain interacts with CD4 molecule of helper T cells during antigen presentation.

Differences between MHC class I and II molecules is described in Table 14.8.

TABLE 14.8: Differences between MHC class I and MHC class II molecules

	MHC class I	MHC class II
Present on	All nucleated cells (except sperms) and platelets	Antigen presenting cells (APCs)
Peptide antigen is	Presented to CD8 T cells	Presented to CD4 T cells
Nature of peptide antigen	Endogenous or intracellular (viral/ tumor antigen)	Exogenous
Peptide antigen (size)	8–10 amino acid long	13–18 amino acid long
Antigen presentation pathways	Cytosolic pathway	Endocytic pathway
Peptide-binding site	α1/α2 groove	α1/β1 groove
CD4 or CD8 binding site	α3 binds to CD8 molecules on T_C cells	β2 binds to CD4 on T_H cells

Contd...

MHC Polymorphism

MHC molecules are involved in antigen processing and presentation to the T cells. Each MHC molecule specifically presents a certain antigenic peptide to the T cells. Since there is a wide spectrum of different antigenic peptides (with specific sequences) derived from various antigens; there is a likewise need of different MHC molecules capable of recognizing these peptides. This is made possible by the polymorphic feature of MHC genome; by which it is capable of producing a wide array of MHC molecules with vast antigenic specificities. There are three mechanisms by which MHC molecules show such a high level of pleomorphism.

- **Multiple gene loci:** Both MHC class I and II molecules are coded by multiple genes. Gene of each locus codes for a similar but not identical chain. For example:
  - MHC I molecules (α chain) are coded by any of the three loci of class I region, i.e. HLA-A or B or C loci
  - MHC II molecules (α and β chains) are coded by any of the three loci of class II region, i.e. DP or DQ or DR loci.
- **Multiple allele for each locus:** In a given species, extraordinarily large numbers of different alleles are known to exist for each locus. MHC genes are one of the most polymorphic genes known. For example:
  - For class I MHC region in humans, there are 240 alleles for HLA-A, 470 alleles for HLA-B and 110 alleles for HLA-C. The MHC class I region of any individual would have one of the allele from each HLA-A, B and C allele bank.
  - So, there are total 240 × 470 × 110 number of theoretical combinations possible for class I MHC region. These alleles encode for products that vary from one another by 5–10% of their DNA sequence.
  - Similar polymorphism also exists for alleles of class II DP, DQ and DR loci.
- **Codominant expression:** MHC genes are expressed in *codominant fashion*, i.e. the alleles inherited from parents (one from father and one from mother) are simultaneously and equally expressed.

Contd...

TABLE 14.9: Diseases associated with certain HLA alleles

HLA allele	Associated disease
HLA B27	Ankylosing spondylitis, Reactive arthritis (*Yersinia, Salmonella*, gonococcus) and Reiter's syndrome
DR-2	Multiple sclerosis, Goodpasture's syndrome
DR-3	Myasthenia gravis, systemic lupus erythematosus
DR-3/DR-4	Insulin-dependent diabetes mellitus
DR-4	Rheumatoid arthritis
A3/B14	Hereditary hemochromatosis

Regulation of MHC Expression

There are several regulatory mechanisms that control the expression of MHC genes in different cell types.

- **Transcription factors:** MHC genes have promoter sequences at their 5′ end which are regulated by certain transcription factors such as **CIITA**, and **RFX** (both bind to MHC II promoter genes and increase their transcription). Defects in CIITA, and RFX cause one of the form of **bare lymphocyte syndrome**.
- **Cytokines** also influence MHC expression.
  - IFN-γ activates both MHC-I and II promoter genes.
  - IL-4 increases expression of class II MHC molecules on resting B cells.
- **Corticosteroid and prostaglandins** decrease the expression of MHC II molecules.
- **In many viral infection**, the viral antigens inhibit various components of MHC-I (e.g. adenovirus proteins inhibit TAP, cytomegalovirus proteins inhibit β2 microglobulin). As a result, MHC-I expression is suppressed.

MHC and Disease Susceptibility

Many HLA alleles have been associated with increased susceptibility to certain diseases (Table 14.9). The relative risk of occurrence of the disease in presence of the identified allele varies. For example, HLA B27 is strongly associated with ankylosing spondylitis (90 times higher risk than those not expressing HLA B 27).

SOLUBLE PRODUCTS OF LYMPHOID CELLS

CYTOKINES

Definition

Cytokines are chemical substances which serve as messengers, mediating interaction and communication between the various cells of immune system.

Major Classes of Cytokines

Present nomenclature of cytokines includes all the compounds that were known earlier by various names, such as:

- Lymphokines—produced by lymphocytes
- Monokines—produced by monocytes and macrophages
- Interleukins—produced by WBCs and acting on the same or different WBCs
- Chemokines—involved in chemotaxis and other leukocyte behavior.

Properties of Cytokines

Cytokines are comparable with growth factors and hormones in many ways such as all of them act at very low concentration (picomoles) and through specific receptors. However, there are some differences also.

- Growth factors are produced constitutively while cytokines are inducible, i.e. produced only after the activation of their cells of origin.
- Hormones have mostly endocrine effects whereas cytokines have broad range of effects, which include (Fig. 14.14):
  - Autocrine effect—that acts on the same cell
  - Paracrine effect—that acts on the adjacent cell
  - Endocrine effect—that acts on a cell present at a distant site.
- Unlike hormones and growth factors which work mostly independently, cytokines can work together and there are various types of interactions occurring between cytokines:
  - **Pleiotropy and redundancy effect:** Pleiotropy refers to same cytokine having different actions on different target cells, whereas redundancy implies to different cytokines producing the same effect on the same target cell (Fig. 14.15).
  - **Synergy and antagonism effect:** Two cytokines may augment each other's action producing a larger effect (synergism) or may oppose each other's action (antagonism).

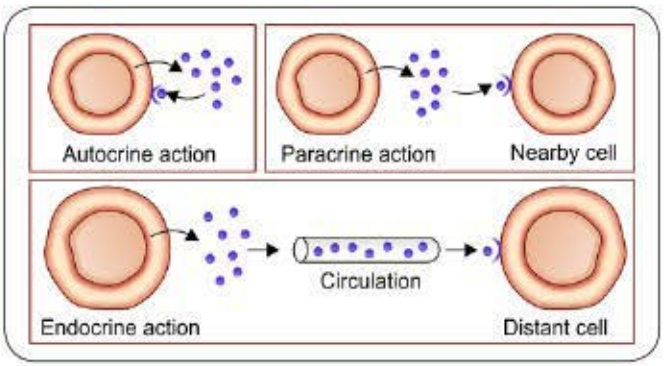

Fig. 14.14: Action of cytokines on target cell

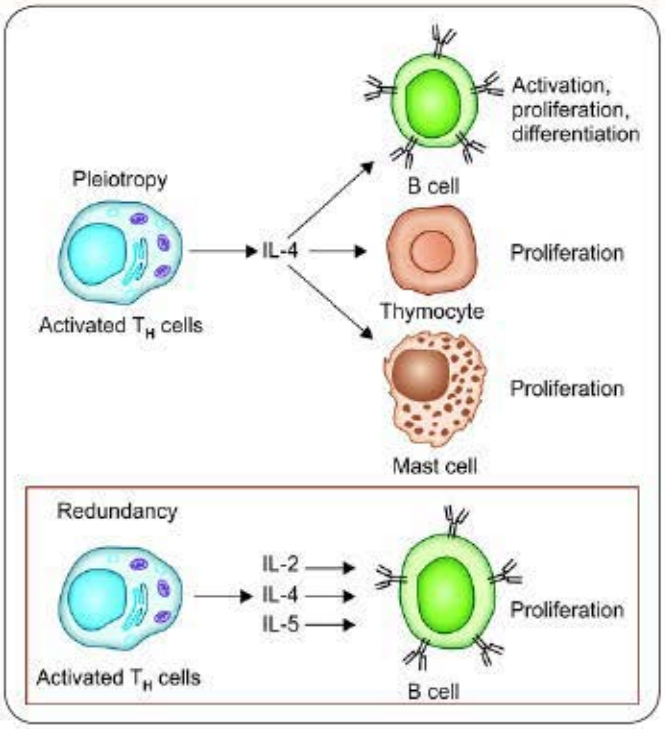

Fig. 14.15: Pleiotropy and redundancy effect of cytokines

- **Cascade effect:** It refers to a series of effects mediated by different cytokines. One cytokine acts on a target cell to produce another cytokine which in turn acts on another target cell and so on.

Structure of Cytokines

Cytokines are glycoproteins with molecular weight less than 30 kDa. Most cytokines display high degree of α-helix structure but no β-structure. Cytokines characterized so far belong to one of the four groups—the hematopoietin family, the interferon family, the chemokine family, or the tumor necrosis factor family; each interacting with a separate class of cytokine receptors present on target cell surface.

Functions of Important Cytokines

Though cytokines are secreted by a wide variety of cells, the major producers are T_H cells and macrophages. Cytokines produced have a range of overlapping functions on the target cells/tissues, which can be broadly categorized into two groups:

1. Promote development of cellular and humoral responses of adaptive immunity:
   - Interferon-γ
   - Cytokines such as IL-2, IL-4, IL-5
2. Cytokines promote various responses of innate immunity:
   - Induction of inflammatory responses—by IL-1, IL-8, TNF-α
   - Regulation of hematopoiesis—by colony stimulating factors, IL1, IL-3, IL-7, IL-9, IL-11, etc
   - Antiviral activity—By interferon- α and β
   - Antitumor activity—By TNF- α and β
   - Pyrogenic activity—By TNF- α, IL-1 and IL-6.

The functions of individual cytokines are summarized in Table 14.10. Cytokines of cellular and humoral immune responses are also discussed in Chapter 15.

Cytokines and Diseases

Pathogenesis of many diseases is characterized by increased expression of cytokines or their receptors. Common examples include the following:

- **Septic shock** due to gram-negative bacteria, such as *Escherichia coli* or *Neisseria meningitidis* is mediated by the endotoxins released by bacteria that stimulate macrophage to produce IL-1 and TNF-α.
- **Toxic shock syndrome** is caused by the toxin released from *Staphylococcus aureus* which activates T cells nonspecifically leading to massive cytokine release and that in turn activates macrophages to release large quantities of IL-1 and TNF-α.
- **Cancers:** Several malignancies have been associated with ↑IL-6, e.g. cervical cancer, bladder cancer, etc.
- **Chaga's disease** is caused by a parasite named *Trypanosoma cruzi* which is shown to inhibit the IL-2α receptor, thus blocking the IL-2 action → leading to inhibition of T_H1 activity → immunosuppression.
- Cytokine storm (see below).

Cytokine Storm

It is a condition, where the cytokines are produced in excess leading to **hypercytokinemia** which can cause significant damage to body tissues and organs.

- Normally, the production of cytokines is kept in check by the body. However, in some instances, the reaction becomes uncontrolled, and too many immune cells are activated in a single place.
- The precise reason for this is not entirely understood but may occur in a number of infectious and noninfectious diseases, including graft versus host disease (GVHD), acute respiratory distress syndrome (ARDS), sepsis, Ebola, avian influenza, smallpox, and systemic inflammatory response syndrome (SIRS).

Cytokines used in Therapy

Cytokines offer great promise for the treatment of a number of diseases. Many strategies have been followed to create a cytokine or anti-cytokine state in the body depending on the need. The strategies are:

TABLE 14.10: Sources and functions of cytokines

Cytokine	Cytokine secreting cells	Target cells and Functions
Interleukins (IL)		
IL-1	Produced by all nucleated cells, but principal sources are APCs, such as macrophages, monocytes, dendritic cell, B cells and endothelial cell	▪ T_H cells - IL1 produced by APCs stimulates T_H cells activation and proliferation • Promotes IL2 secretion by T_H cells • Induces IL-2 receptor expression on T_H cells • Induces ↑MHC-II expression on APCs ▪ B cell—promotes B cell development and maturation ▪ Liver—induces synthesis of acute phase reactant proteins ▪ Hypothalamus—induction of fever ▪ Macrophage and neutrophil activation—↑expression of ICAM
IL-2	T_H 1 cells	Induces proliferation activated T_H cells, T_C cells and some NK cells (Previously called as T cell growth factor)
IL-3	T_H cell, NK cell, Mast cell	▪ Stimulates hematopoiesis (acts as multi-CSF) ▪ Mast cell degranulation—↑ histamine secretion
IL-4	T_H 2 cells	▪ T_H cells—promote T_H 2 cell activity and inhibit T_H 1 cell ▪ B cell—promotes B cells activation and proliferation and induce B cell class switch over to produce IgE, IgG4, IgG1; previously called as B cell growth factor ▪ Macrophage and APCs—induce ↑MHC-II expression
IL-5	T_H 2 cells	Promote eosinophil growth and differentiation
IL-6	T_H 2 cells, macrophages	IL-1 and TNF like effects (synergistic effect) Promotes B cell proliferation and antibody production
IL-7	Bone marrow/thymic stromal cells	Serves as a growth factor for T cell and B cell precursors.
IL-8	Macrophages, endothelial cells	Attracts neutrophils, NK cells, eosinophils and basophils.
IL-9	T_H cells	Hematopoietic and thymopoietic effects
IL-10	T_H 2 cells	Reduces cytokine production by T_H1 cell
IL-11	Bone marrow stromal cells	▪ Hematopoietic effect (B cell and platelet development) ▪ Liver—induce synthesis of acute phase reactant protein
IL-12	Macrophages	Promote T_H 1 cell induction and inhibit T_H2 activity; promotes CMI responses NK cell stimulatory factor
IL-13	T_H 2 cells	Mimic IL-4 function
IL-17	$CD4^+$ activated memory T_H cell	Initiates and maintains inflammation
Interferons (IFN)*		
IFN-α	Leukocytes	Antiviral activity
IFN-β	Fibroblasts	Antiviral activity
IFN-γ	T_H and T_C cells, NK cells	▪ Macrophage—Activates the resting macrophages into activated macrophage ▪ B cells—Activate B cells to produce IgG ▪ Promotes inflammation of delayed type of hypersensitivity (along with TNF-β) ▪ T_H2 cell—Inhibits T_H 2 cell proliferation
Tumor necrosis factors (TNF)		
TNF-α	Macrophage	▪ IL-1 like effect ▪ Tumor cells—Promote vascular thrombosis and tumor necrosis ▪ Inflammatory cells—Induce cytokine secretion ▪ Induces lipolysis, causes extensive weight loss associated with chronic inflammation
TNF- β	T_H 1 cell and T_C cell	Tumor cells—Similar effect like TNF-α Macrophage—Enhance phagocytic activity
Colony-stimulating factor(CSF)		
GM-CSF	Fibroblasts, endothelium, T cells, macrophages	Macrophage and granulocyte growth stimulation
G-CSF	Bone marrow stromal cells, macrophages	Granulocyte growth stimulation
M-CSF	Fibroblasts, endothelium	Macrophage growth stimulation

Contd...

Contd...

Others		
TGF- β	Macrophages, mast cells T and B cells, platelet	▪ Inhibit T and B cell proliferation and hematopoiesis: ▪ Promote wound healing ▪ Promotes class switching of B cells to the IgA class

ICAM-1, intercellular adhesion molecule 1; TGF-β, transforming growth factor- β

*Interferons are discussed in detail in Chapter 41

- **Use of cytokines (e.g. interferons) as drug:**
  - Interferon-α is used for the treatment of hepatitis B, hepatitis C, hairy cell leukemia, multiple myeloma and Chronic myeloid leukemia (CML).
  - Interferon-β is used for the treatment of multiple sclerosis.
  - Interferon-γ is used for the treatment of chronic granulomatous disease.
- **Cytokine-toxin conjugates** are used to destroy the target cells; here the cytokines help in binding to the target cells so that the toxin can act on.

EXPECTED QUESTIONS

I. Essay:

1. Describe in detail about the structure and function of various lymphoid organs and cells of immune system.

II. Write short notes on:

1. Major histocompatibility antigen
2. Cytokines
3. Dendritic cells
4. Development of T cells
5. Development of B cells
6. MALT

III. Multiple Choice Questions (MCQs):

1. T cell area of lymph node is:
   a. Cortex
   b. Medulla
   c. Paracortical area
   d. All of the above

2. Which one of the following cytokine induces fever?
   a. IL-2
   b. IL-1
   c. IL-4
   d. IL-5

3. All of these are antigen presenting cells (APC's) except:
   a. T cells
   b. B cells
   c. Dendritic cells
   d. Macrophage

4. Cell type which lacks HLA antigen is:
   a. Monocyte
   b. Thrombocyte
   c. Neutrophil
   d. Red blood cell

5. Interferon gamma is secreted by:
   a. Macrophage
   b. Fibroblasts
   c. Activated T-cell
   d. Neutrophils

Answers

1. c **2.** b **3.** a **4.** d **5.** c

CHAPTER 15
Immune Responses: Cell-mediated and Antibody-mediated

Chapter Preview

- Antigen presentation
- Helper T cells (activation and differentiation)
- Cell-mediated immune response
- Humoral/antibody mediated immune response

INTRODUCTION

Immune response refers to the highly coordinated reaction of the cells of immune system and their products. It has two arms (Fig. 15.1).

Humoral or Antibody-mediated Immune Response (AMI)

It provides protection to the host by secreting *antibodies*; that can bind and neutralize microbial antigens circulating free or present on the surface of the host cells and in the extracellular spaces, but have no role against intracellular antigens. If antibodies were the only agents of immune response, pathogens that manage to evade them by being in the intracellular environment would have escaped the immune response. Nevertheless, this is not the case.

Cell-mediated Immune Response (CMI)

It plays a crucial role in providing protection against intracellular microbes as well as tumor cells. Although CMI is mainly T cell mediated (especially cytotoxic T cells); however, various other effector cells such as NK cells, macrophages, granulocytes are also component of CMI.

CMI and AMI are Interdependent

CMI and AMI cannot work individually, but they are highly dependent on each other (Fig. 15.1). Cytokines released from T cells which stimulate B cells to produce antibodies. Similarly, many effector cells of CMI such as macrophages and NK cells use antibodies as receptors to recognize the target cells for killing.

CMI also regulates the humoral immunity by releasing cytokines from activated T cells that stimulate the B cells to transform into antibody secreting plasma cells.

There are certain initial events that must take place before the induction of either CMI or AMI. These events are common to both CMI and AMI, and they occur irrespective of the type of immune response that will follow. These events include:

- Antigen presentation to helper T cells
- Activation and differentiation of helper T cells into either T_H1 or T_H2 subsets

Helper T (T_H) cells are the central key that regulates the type of immune response that is going to occur. Activated helper T cells differentiate into either T_H1 or T_H2 subsets. Induction of T_H1 cells secrete cytokines that stimulate cell mediated response, whereas if T_H2 cells are differentiated, they secrete certain cytokines that in turn induce the B cells to produce antibodies.

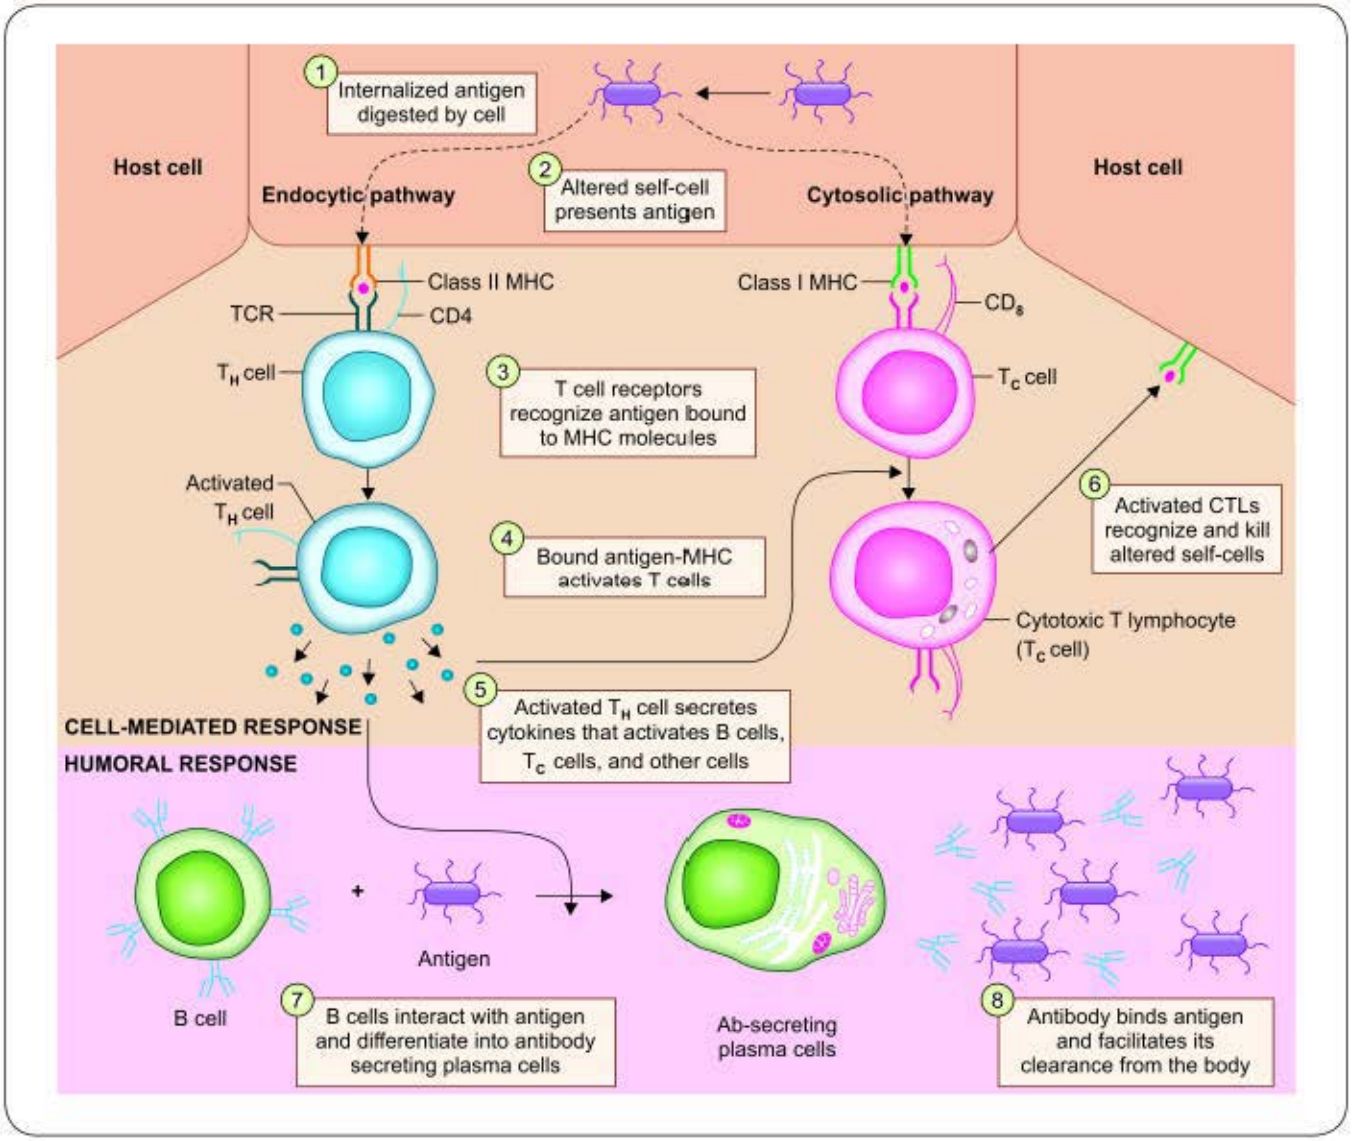
ANTIGEN PRESENTATION

For induction of immune responses, recognition of antigens by T cells is essential. T cells cannot recognize the native and free antigens, but they do so only after the antigen is processed into smaller antigenic peptides containing specific epitopes which are subsequently combined with MHC molecules (class I or II) and presented on the host cell surface.

Antigen-presenting Cells (APCs)

Although antigen presentation refers to presentation of antigenic peptide to both T_H (helper T cells) and T_C (cytotoxic T cells) by complexing with MHC-II and I respectively; however, antigen-presenting cells (APCs) in strict sense implies only to those cells (e.g. dendritic cell, macrophage, etc.) that present the antigenic peptide along with MHC class II to T_H cells (Table 15.1).

Cells presenting antigenic peptides along with MHC class I molecules to T_C cells are not included under APCs. These cells are usually virus infected cells or tumor cells. They are often referred to as **target cells** as the activated T_C cells cause lysis of these cells.



1 Internalized antigen digested by cell
Host cell
Endocytic pathway
2 Altered self-cell presents antigen

7 B cells interact with antigen and differentiate into antibody secreting plasma cells
Ab-secreting plasma cells
8 Antibody binds antigen and facilitates its clearance from the body

Fig. 15.1: Overview of immune response

TABLE 15.1: Antigen-presenting cells (APCs)

Professional APCs	Nonprofessional APCs
Dendritic cells	Fibroblasts (skin)
Macrophages	Thymic epithelial cells
B cells	Pancreatic beta cells
	Vascular endothelial cells
	Glial cells (brain)
	Thyroid epithelial cells

Dendritic cells, macrophages and B cells are the major APCs and are called **professional APCs**. There are some other non-professional cells that can occasionally present antigens to helper T cells.

Antigen Processing Pathways

For induction of immune response (both CMI and AMI), antigens must be presented to T_H cells. In addition, for CMI induction, antigen presentation to T_C cells is essential. Two well defined pathways used by the immune system are known. They are different from each other in their mechanism and target antigen, as given follows (Table 15.2):

1. **Cytosolic pathway:** Here, the endogenous (intracellular) antigens such as viral antigens and tumor antigens are processed and presented along with MHC class I molecules to CD8 T cells.
2. **Endocytic pathway:** In this pathway, the exogenous antigens (extracellular microbes and their products, e.g. toxins) are processed and complexed with MHC

TABLE 15.2: Differences between cytosolic and endocytic pathways of antigen presentation

Property	Cytosolic pathway	Endocytic pathway
Antigen processed	Endogenous	Exogenous
Antigen is complexed with	MHC I molecules	MHC II molecules
Antigen is presented to	T_C cells	T_H cells

class II molecules and presented to T_H cells. The cells involved in endocytic pathway include the APCs such as macrophages, dendritic cells and B cells.

HELPER T CELLS (ACTIVATION AND DIFFERENTIATION)

Helper T cell (T_H) activation and differentiation is the central event that regulates both the components of immune response; CMI and AMI.

Activation of Helper T Cells

Signal Generation

Activation of T_H cells requires generation of two specific signals (Fig. 15.2).

1. **Antigen-specific signal:** It involves binding of antigenic peptide present in the groove of MHC-II on APCs to TCR (T cell receptor) present on surface of T_H cells. CD4 molecules of T_H cells also interact with β2 domain of MHC-II.
2. **Costimulatory signal:** It involves binding of CD28 molecule on T_H cells to B7 molecules on APCs. APCs (macrophages) secrete interleukin-1 (IL-1) which acts on T_H cells.

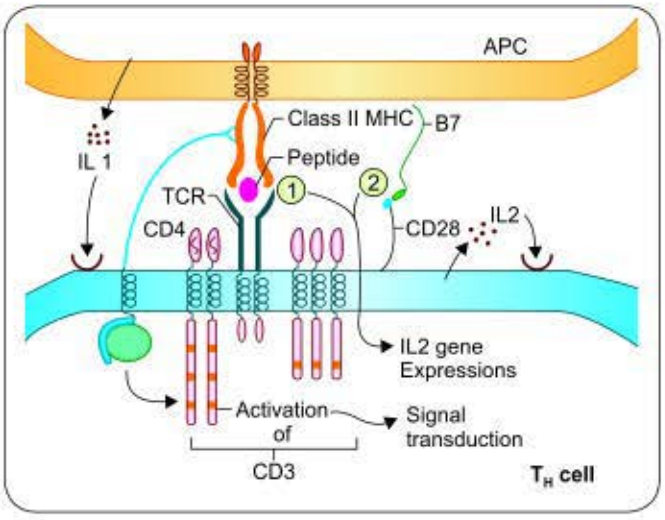

Fig. 15.2: Activation of T_H cell by interacting with APC

Signal Transduction

Following induction of signal, its transmission is essential for T_H cell activation. Signal transduction is initiated at CD4 molecule which interacts with CD3 complex, which in turn transmit the signal leading to activation of T_H cells.

Differentiation of Helper T cells

Activated T_H cells secrete increased amount of IL-2 as well as IL-2 receptor (IL2R or CD25). IL-2 binds to its receptors on the same T_H cell and also on other T_H cells and induces the naive T_H cells to proliferate and differentiate. T_H cells get activated and become lymphoblast cells which subsequently differentiate into memory and effector T_H cells.

Effector T_H cells

They are derived either from the naive T_H cells or pre-existing memory T_H cells following antigenic stimulus. They are short lived (few days to weeks). They further **differentiate into either T_H1 or T_H2** subsets. This differentiation is very crucial as they secrete distinct cytokines that further mediate specific functions.

Cytokines secreted by T_H1 cell stimulate cytotoxic T cells and induce cell mediated immune response; while cytokines secreted by T_H2 cell stimulate B cells producing different classes of antibodies (humoral immune responses). **IL12** secreted by macrophage plays an important role in the differentiation of T_H cells. It promotes T_H1 subset proliferation.

- **T_H1 cells** produce IL-2, interferon-γ (IFN-γ) and tumor necrosis factor-β (TNF-β); each has specific function (Table 15.3)
- **T_H2 cells** secrete IL-4, IL-5, IL-6, IL-10 and IL-13. They activate the B cells to transform into plasma cells which in turn secrete antibodies (Table 15.3).

Memory T Cells

They are derived from activated T_H cell. They have longer life span (months to years). They are in resting stage, but following subsequent antigenic stimulus, they become activated and differentiated into effector T_H cells. They express CD45RO isoform of common leukocyte antigen CD45, as compared to naive T cells which express CD45RA.

CELL-MEDIATED IMMUNE RESPONSE

The term cell-mediated immune response (CMI) refers to destruction of cells carrying intracellular microbes and other abnormal cells, such as tumor cells by various specific and nonspecific cells of immune system, of which the most important is cytotoxic T (T_C)cells.

TABLE 15.3: Role of cytokines secreted by T_H1 and T_H2 cells

T_H1 cytokines and their functions	
IL-2	▪ Promotes activation of T_H and T_C cells ▪ Activates NK cells to become LAK cells
IFN-γ	▪ Activates the resting macrophages into activated macrophage ▪ Activates B cells to produce IgG ▪ Promotes inflammation of delayed type of hypersensitivity (along with TNF-β) ▪ Inhibits T_H2 cell proliferation
TNF-β	Enhances phagocytic activity of macrophage
T_H2 cytokines and their functions	
IL-4	▪ Inhibits T_H1 cell differentiation ▪ Stimulates B cells to produce IgE and also IgG4 and IgG1
IL-5	▪ Enhances proliferation of eosinophils ▪ Both IL-4 and IL-5 together provide protection against helminthic infections and also mediate allergic reaction
IL-6	Promotes B cell proliferation and antibody production
IL-10	Inhibits T_H1 cell differentiation

Abbreviaitons: LAK cell, lymphokine-activated killer cells; IFN, interferons; IgG, immunoglobin G; TNF, tumor necrosis factor; NK, natural killer

Role of CMI

CMI mediates the following immunological functions:

- Provides immunity against microbes residing in intracellular milieu:
  - For obligate intracellular organisms, CMI remains the only effective immune response. Examples include all viruses, some bacteria (*Mycobacterium, Chlamydia* and *Rickettsia*), some parasites (*Plasmodium, Leishmania, Trypanosoma and Cryptosporidium*) and some fungi (*Pneumocystis*).
  - For facultative intracellular organisms, humoral immunity is active as long as the organism is extracellular. Once they come to intracellular milieu, CMI takes the leading role. Examples include Bacteria like *Listeria, Salmonella* and *Yersinia* and fungi such as *Histoplasma* and *Cryptococcus.*
- Provides immunity against tumor cells and other damaged and altered cells.
- Mediates delayed hypersensitivity (type IV hypersensitivity).
- Plays key role in transplantation immunity and graft-versus-host (GVH) reaction.

Effector Cells of CMI

CMI can be mediated by both antigen specific and nonspecific effector cells (Table 15.4). They perform their function by direct killing of the target cells (e.g. virus infected cells or tumor cells).

TABLE 15.4: Effector cells of CMI

Effector cells of CMI	Antigen specificity
Cytotoxic T cells	Specific
NK cells	Nonspecific
Cells performing ADCC (NK cells, macrophages, neutrophil and eosinophils)	Nonspecific

Abbreviations: ADCC, antibody-dependent cell-mediated cytotoxicity; NK, natural killer

- The most important mediator of CMI is cytotoxic T cell which is antigen specific.
- However, many other non-specific effector cells such as macrophages, NK cells, neutrophils, and eosinophils also contribute to CMI.
- Although CMI has many features distinct from humoral immune response but it is not completely independent. The nonspecific effector cells use antibodies as receptors to recognize the target cells for killing.

Cytotoxic T Lymphocytes

CD8 cytotoxic T lymphocytes (CTL or T_C) are the principal effector cells of CMI, involved in the destruction of target cells such as virus infected host cells and tumor cells. Naive T_C cells (or CTL precursors) respond to viral or tumor peptide antigens which are processed by the target host cells (by cytosolic pathway) and presented along with MHC class I molecules. Activated T_C in turn secretes cytotoxic enzymes that lyse the target cells.

Activation of CTL

Generation of activated CTL from naive T_C cells requires induction of at least three signals (Fig. 15.3):

1. **Antigen-specific signal:** It is induced by binding of TCR-CD3 complex of naive T_C cells to MHC I -peptide

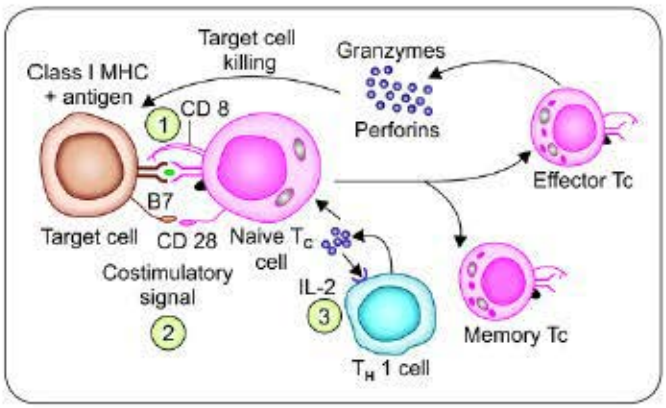

Fig. 15.3: Activation and differentiation of T_C cells

complex of target cells. CD8 of T_C cells also interacts with α3 domain of MHC-I.

2. **Costimulatory signal:** CD28 of naive T_C cells interacts with B7 molecule on target cells.
3. **Third signal:** IL-2 (secreted by T_H1 cell) acts on high-affinity IL-2 receptor on T_C cells.

Following induction, the transmission of signal occurs in a way similar to that described for T_H cells.

Functions of CTL (Target Cell Lysis)

The activated T_C cells produce two types of lethal enzymes; called perforins and granzymes.

- **Perforins** produce pores in the target cell membrane; through which granzymes are released inside.
- **Granzymes** are serine proteases; they induce cell death by apoptosis through caspase pathway.

Natural Killer Cells

NK cells are large granular lymphocytes that constitute 10-15% of peripheral blood lymphocytes.

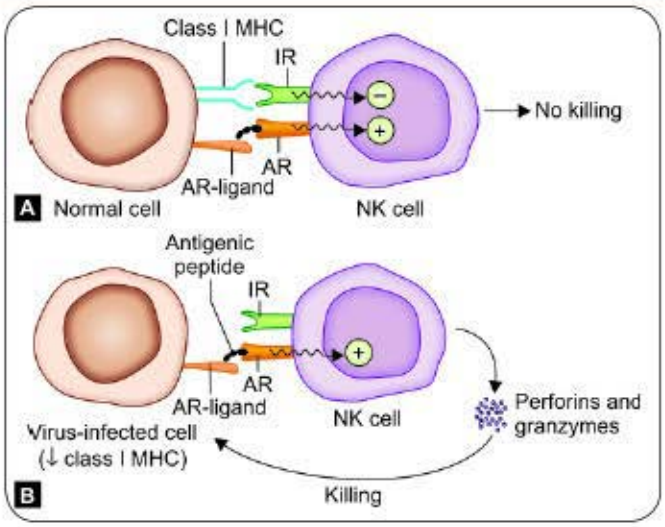
- They are derived from a separate lymphoid lineage. NK cells are cytotoxic, but antigen non-specific.
- They are part of innate immunity, act as first line of defense and do not require prior contact with the antigen.

NK cells act against virus infected cells and tumor cells till the T_C cells are activated and take over the function. However, they differ from T_C cells in many other aspects (Table 15.5) such as:

- **NK cell markers:** NK cells lack the T cell markers such as CD3, CD4 or CD8 molecules (hence are also called null cells), instead possess specific surface markers such as CD16 and CD56.
- **No MHC restriction:** NK cells can recognize the ligands (antigens) without MHC presentation.

TABLE 15.5: Comparison between NK cells and T_C cells

Property	NK cells	T_C cells
Surface markers	CD16 and CD56	CD3, CD8
MHC restriction	No	MHC-I restricted
Memory	No	Yes
Immunity	Part of innate immunity	Part of acquired immunity
Target cell	Virus infected cells Tumor cells	Same as NK cells
Mechanism of destruction	Perforins and granzymes (constitutive)	Same as NK cells (inducible)
Immune response	CMI	CMI



Figs 15.4A and B: NK cell-mediated cytotoxicity. **A.** In normal cell; **B.** In virus infected cell
Abbreviations: AR, activation receptor, IR, inhibtion receptor

- **Innate immunity:** NK cells are part of innate immunity; they do not require the prior exposure to microbial antigen.
- **No memory:** NK cells do not differentiate into memory cells.

Mechanism of NK Cell-mediated Cytotoxicity

Receptor Interaction

NK cells are not MHC restricted. They directly recognize certain ligands (e.g. glycoproteins) present on the surface of altered host cells like virus-infected cells or tumor cells. However, such ligands are also present on normal cells. Still, NK cells are capable of distinguishing normal host cells from the altered cells (Figs 15.4A and B). This is mediated by two types of receptors present on NK cell surface **(theory of opposing-signals model).**

- **Activation receptors** (e.g. NKR-P1, CD16): When these receptors are engaged with ligands present on the target cells; NK cells become activated.
- **Inhibitory receptors** (such as C-type lectin inhibitory receptors): They recognize a part of MHC I molecule (HLA-E) which is present on the surface of all normal nucleated cells.
  - Binding of inhibitory receptors to MHC-I molecules generates an inhibitory signal that suppresses the NK cells even if they are bound to the activation receptors. This is because the inhibitory signal is the dominant signal and hence it overrides the activation signal.
  - However, in virus infected cells and tumor cells, the MHC-I expression is remarkably reduced. In such

cases, there would not be any inhibitory signal. Hence, binding of activation receptor to its ligand leads to activation of NK cells.

Target Cell Destruction

Mechanism of target cell lysis by NK cells is similar to that of T_C cells, i.e. via secreting perforins and granzymes. Perforins forms pore on target cells, through which granzymes enter and lyse the target cells (Fig. 15.4B). The only difference is that, the enzymes are constitutively expressed in NK cell cytoplasm (i.e. they are cytotoxic all the time, even without exposure to the antigen).

Alternate Mechanism of NK Cell Activity

- NK cells respond to IL-12 produced by macrophages and secrete IFN-γ, which in turn activates the macrophages. Then, the activated macrophages phagocytose and kill the microbes.
- NK cells also mediate their function via ADCC (described below).

Antibody-dependent Cell-mediated Cytotoxicity (ADCC)

A number of nonspecific cytotoxic cells express receptors (FcR) on their surface that can bind to the Fc region of any immunoglobulin.

- Following contact with a target cell coated with an antibody, these FcR bearing cells can bind to Fc portion of the antibody coated on the target cells, and subsequently cause lysis of the target cell.
- Although these cytotoxic cells are nonspecific for the antigen, the specificity of the antibody directs them towards the specific target cells. This type of cytotoxicity is referred to as **antibody-dependent cell-mediated cytotoxicity (ADCC)**.

ADCC is exhibited by various cells such as NK cells, macrophages, monocytes, neutrophils, and eosinophils. They release various cytotoxic factors into the target cells like perforins, granzymes, lytic enzymes, free radicals, TNF, etc. (Fig. 15.5). However, there is no complement dependent cytolytic activity.

- NK cells secrete perforins, and granzymes. Neutrophils release lytic enzymes.
- Eosinophils can release lytic enzymes and perforins; play an important role in providing immunity against helminths.
- Macrophages produce lytic enzymes and TNF.

Assessment/detection of CMI

There are several methods for detection of CMI.

- The mixed-lymphocyte reaction (MLR) is an *in vitro* system for assaying T-cell proliferation in a cell mediated response.

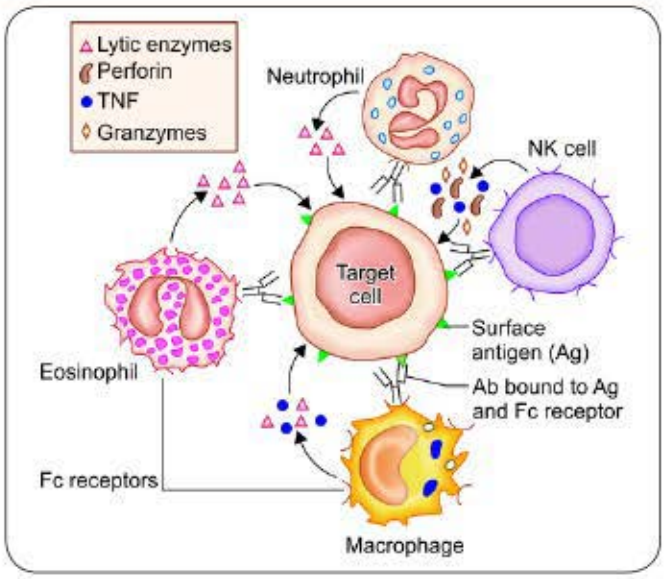


Fig. 15.5: Cytotoxic factors released by various cells in ADCC

- Cell-mediated lympholysis (CML) is another *in vitro* assay for testing the cytotoxic function of effector cells of CMI.
- The graft-versus-host reaction (GVH) in experimental animals provides an *in vivo* system for studying cell-mediated cytotoxicity.

HUMORAL/ANTIBODY-MEDIATED IMMUNE RESPONSE (AMI)

Antibody-mediated immune response (AMI) provides protection to the host by **secreting antibodies;** that prevent invasion of microbes present on the surface of the host cells and in the extracellular environment, but has no role against intracellular microbes. AMI occurs through the following three sequential steps:

1. Activation of B cells following contact with the microbial antigen (B cells act as APCs).
2. Proliferation and differentiation of B cells into effector cells (antibody producing plasma cells) and memory cells.
3. Effector function: Production of secreted antibodies by plasma cells which in turn counter act with the microbes in many ways, such as neutralization, opsonization, complement activation, etc.

Activation of B Cells

Antigens that activate B cells fall into two categories.

1. Most antigens are **thymus dependent (TD)**; they activate B cells indirectly via activation of T cells. TD antigens are processed by APCs, presented to T_H cells following which the activated T_H cells secrete cytokines that in turn activate the B cells.

2. The thymus independent (TI) antigens (e.g. bacterial capsule) are not processed by APC. They can directly activate B cells without the help of T cell induced cytokines (for details refer Chapter 10).

TD antigens induced activation of B cell is described below.

Antigen Presentation of B Cells to Activated T_H Cells

The first and foremost step that occurs is recognition of microbial antigen (TD antigen) by B cell membrane immunoglobulin receptors (mIg) followed by receptor-mediated endocytosis of antigen. Then the antigen is processed into smaller antigenic peptides that are presented in complex with MHC-II to activated T_H cells (by endocytic pathway). This leads to induction of two signals.

Signal Induction

The naive B cells are in the resting stage. Activation requires induction of three signals (Fig. 15.6).

1. **Signal 1:** It is induced by the cross linking of IgM on B cell membrane with the microbial antigen.
2. **Signal 2:** It is an additional signal provided by binding of CD40 on B cell with CD40L (ligand) on activated T_H cells.
3. **Signal 3:** It is usually a cytokine stimulus. Cytokines produced by the activated T_H cells bind to specific cytokine receptor on B cells.

Signal Transduction

Following induction of signal, its transmission is essential for B cell activation.

- Signal transduction is initiated by the B-cell receptor (BCR). The BCR comprises of two parts (Fig. 15.7).
  1. Antigen-binding membrane Ig
  2. Ig-α/Ig-β heterodimer

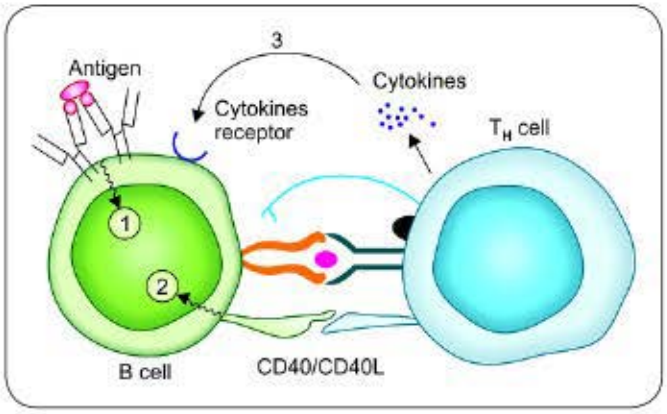

Fig. 15.6: Antigen presentation of B cells to activated T_H cells and signal induction

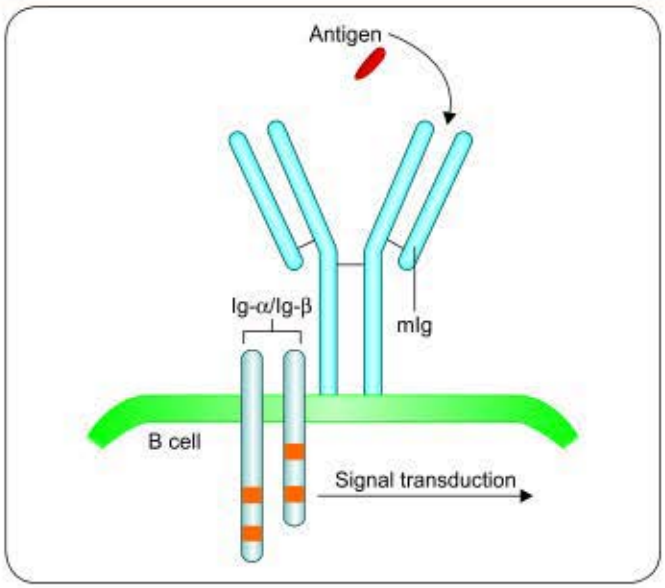

Fig. 15.7: B cell signal transduction

- Following antigen cross linkage to membrane Ig, the Ig-α/Ig-β heterodimer is activated and in turn transmits the signal, ultimately leading to activation of B cells.

Proliferation and Differentiation of B Cells

As described in Chapter 14, the naive B cells, released from bone marrow go and house in the B cell areas of peripheral lymphoid organs (e.g. cortex of lymph node and marginal zone of spleen). There, the naive B cells are organized to form primary lymphoid follicles.

- Following the antigenic exposure, the naive B cells are activated and then they proliferate.
- Eventually, the primary lymphoid follicles transform into secondary lymphoid follicles.
- Secondary lymphoid follicles bear a germinal center which in turn has two areas; dark zone and light zone. Events occurring in the secondary lymphoid follicles are as follows.

Events in the Dark Zone of Germinal Center (Fig. 15.8)

The activated B cells differentiate into larger dividing cells called **centroblasts**, which further transform into smaller non dividing cells called **centrocytes** by expressing membrane Ig.

- Centroblasts express the membrane Ig by undergoing a type of mutation called **somatic hypermutations**. These are point mutations arising due to insertion or deletion in the variable region of Ig gene.
- This results in alteration of the membrane Ig affinity by which it binds with the corresponding antigen. Thus, the resultant centrocytes would bear membrane Ig with altered affinity.

- Because somatic hypermutations occur randomly; they generate membrane Ig with both high and low affinity.
  - The centrocytes with low affinity membrane Ig undergo apoptosis and then are phagocytosed by special type of macrophages found in lymphoid follicles called **tingible body macrophages**.
  - The centrocytes with high affinity membrane Ig are allowed to survive, following which they migrate to the light zone. The process of enhancement of affinity of membrane Ig for antigen binding is called **affinity maturation**.

Events in the Light Zone of Germinal Center (Fig. 15.8)

- **Binding of centrocytes to follicular dendritic cells:** The centrocytes with high affnity membrane Ig undergo maturation by binding to a special type of dendritic cell called **follicular dendritic cell** (see box below). Then the mature centrocytes undergo class switch over.

Follicular Dendritic Cells

The follicular dendritic cells (FDC) are special type of dendritic cells which differ from the other types of dendritic cells in various ways.

- They do not act as APCs and do not express MHC class II. Instead, they bear Fc receptors that recognize Ag-Ab complex.
- Consequently, the antigen is unable to move and is retained in the lymphoid follicle for prolonged periods so that the centrocytes can come and bind to the antigens present in Ag-Ab complex.
- This allows the FDCs to interact with the centrocytes which results in the selection of the centrocytes with high affinity membrane Ig.

- **Class switch over:** Early in the immune response, IgM is the predominant immunoglobulin secreted by the B cells. But as the maturation progresses, the same B cells undergo a phenomenon called **class switch over** to produce Ig of other classess (Fig. 15.8).
  - Class switch over occus in the light zone of lymphoid follicles, where the positively selected centrocytes interact with activated T_H cells and receive a cytokine signal for class switching.
  - Binding of cytokines produced by T_H cells to cytokine receptors present on centrocytes surface induces class switch over.
  - Different cytokines induce production of different classes of Ig by switching mechanism. (Table 15.6)
- **Differentiation of centrocytes into plasma cells and memory cells:**
  - After undergoing class switch over, the selected centrocytes further undergo differentiation into effector cells (plasma cells) and memory cells in the light zone of germinal center.

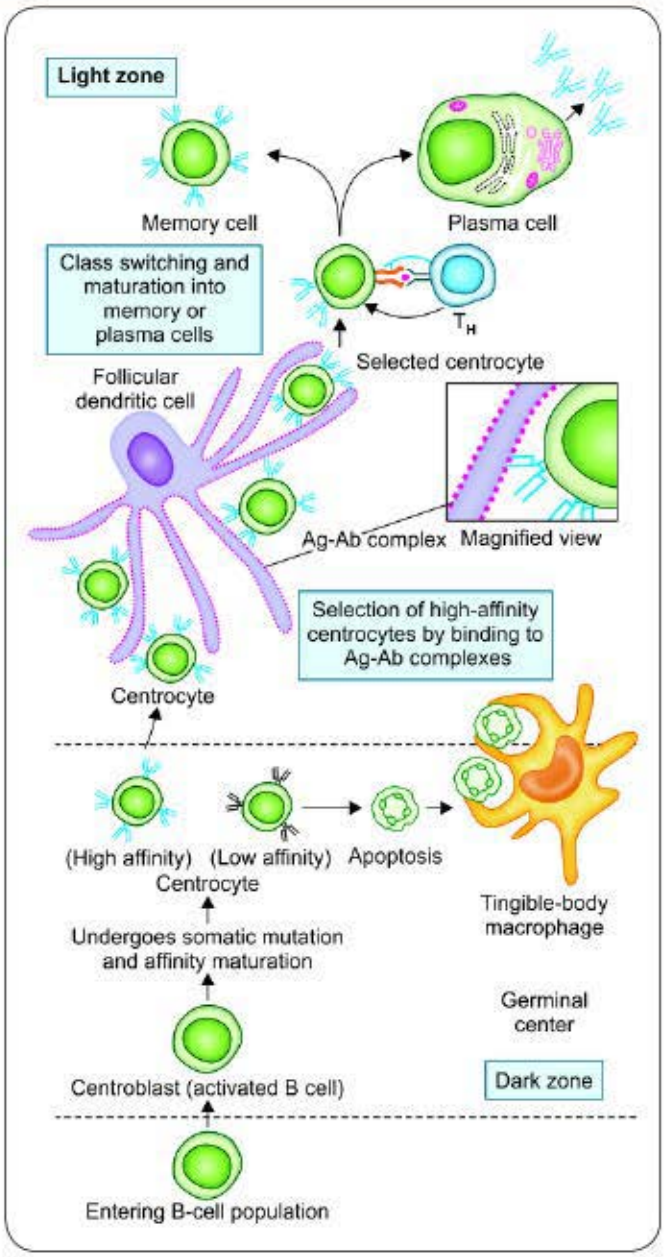

Fig. 15.8: Differentiation of B cells in secondary lymphoid follicles

TABLE 15.6: Cytokines secreted by T_H cells and the respective Ig class/subclass they induce

Cytokine(s)	Ig class produced
IFN-γ	IgG2a or IgG3
IL-5 + TGF-β	IgA or IgG2b
IL-4	IgE or IgG1 or IgG4
IL-2,4,5	IgM
IL-4,5,6 + IFN-γ	IgG

- Plasma cells are large antibody-secreting cells; produce secretory Ig enormously, but do not synthesize membrane Ig. They do not have MHC-II molecules and do not undergo further class switch over.
- Memory cells bear high affinity membrane Ig molecules of all classes as compared to naive B cell that bear only low affinity IgM or IgD membrane Ig. They are long lived cells which respond to the secondary antigenic stimulus.

Effector Functions of AMI

Antibodies secreted from plasma cells mediate a number of biological functions through their Fc portions that bind to Fc receptors (FcRs) expressed by many cell types.

- **Promotes opsonization:** FcRs present on phagocyte surface recognize antibody coated microbes, bind to them and that leads to enhanced phagocytosis (Fig. 15.9).
- **Transcytosis:** Poly-Ig receptors are expressed on the inner (basolateral) surface of epithelial cells (facing the blood). They bind to dimers of IgA and multimers of IgM antibodies and transfer them through the cell to their apical (outer) surface and into the lumen of an organ (e.g. the intestine). This is a process referred to as **transcytosis** and is responsible for the accumulation of antibodies in the lumen of the organ (Fig. 15.10).
- **Mediates mucosal immunity:** Transcytosis of IgA to gut lumen provides mucosal immunity neutralizing the microbes at local mucosal sites.
- **Activates complement-mediated cytolysis:** Antigen antibody complex activates the classical complement pathway (Fig. 15.11). The final complement factors (C5-C9), also called **membrane attack complex** which has lethal activity by forming pores on the target cells.
- **Promotes ADCC:** Though ADCC is principally cell mediated (described under CMI section); antibodies direct the cells to reach to the target cells. ADCC is important to provide immunity against:
  - Helminths (eosinophil-IgE mediated)
  - Tumor cells and virus infected cells (NK cell-IgG mediated)

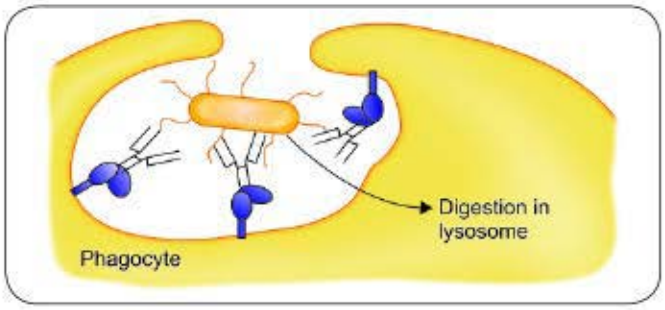

Fig. 15.9: Opsonization of bacteria and phagocytosis

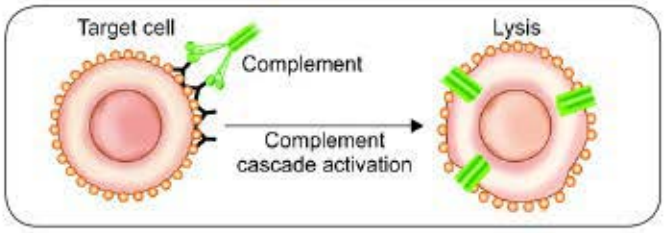

Fig. 15.11: Complement-mediated cytolysis

EXPECTED QUESTIONS

I. Essay:

1. Describe in detail about the mechanism of cell mediated immune response?
2. Describe in detail about the mechanism of antibody mediated immune response?

II. Write short notes on:

1. Antigen presentation
2. ADCC

III. Multiple Choice Questions (MCQs):

1. **Cell-mediated immunity is by virtue of:**
   a. NK cell b. Eosinophil
   c. Cytotoxic T cells d. All above
2. **Macrophages are major source of:**
   a. IL-1 b. IL-5
   c. IL-7 d. IFN-γ
3. **Perforins are produced by:**
   a. Plasma cells b. Suppressor T cells
   c. Cytotoxic T cells d. Memory helper T cells

Answers

1. d **2.** a **3.** c

CHAPTER 16

Hypersensitivity

Chapter Preview

- Definition and classification
- Type-I hypersensitivity reaction
- Type-II hypersensitivity reaction
- Type-III hypersensitivity reaction
- Type- IV hypersensitivity reaction

The purpose of immune response is to eliminate the foreign antigens that have entered into the host. In most instances, immune response leads to only a subclinical or localized inflammatory response which just eliminates the antigen without causing significant damage to the host. However, at times, this response becomes abnormal; leads to exaggerated inflammatory response which causes extensive tissue damage or sometimes even death.

HYPERSENSITIVITY REACTIONS

Definition

The term hypersensitivity or allergy refers to the injurious consequences in the sensitized host, following subsequent contact with specific antigens.

Gell and Coombs Classification

Following an antigen contact, hypersensitivity may occur immediately or after a few days. It may result from abnormality of either humoral or cell mediated immune response. Based on the above two features, Gell and R Coombs classified hypersensitivity reactions into four types (Table 16.1).

Immediate Hypersensitivity Reactions

These reactions occur immediately, within few minutes to few hours of antigen contact, as a result of abnormal exaggerated humoral response (antibody mediated). This can be further classified into three types based on the type of effector mechanisms:

1. **Type I hypersensitivity reaction:** It is IgE mediated, which causes mast cell degranulation following a contact with soluble antigen.
2. **Type II hypersensitivity reaction:** It is IgG (or rarely IgM) mediated which causes complement activation or ADCC (antibody dependent cellular cytotoxicity) in response to cell surface bound antigens.
3. **Type III hypersensitivity reaction:** It is immune complex mediated; which are formed due to interaction between soluble antigen and antibody (usually IgG), resulting in an abnormal inflammatory response.

Delayed Hypersensitivity Reaction

Delayed hypersensitivity reaction occurs after few days of antigen contact, as a result of abnormal cell mediated immune response. This is also called type IV hypersensitivity reaction. It is mediated by a specific subset of T_H cells called delayed hypersensitivity T cells or T_{DTH} cell.

TYPE I HYPERSENSITIVITY REACTION

The hallmark of type I hypersensitivity reaction is production of IgE by sensitized B cells following a contact with an allergen which inturn induces mast cell degranulation. The pharmacologically active mediators released from these granules cause vasodilation, vascular and smooth muscle contraction and increased vascular permeability. These changes ultimately lead to localized response (called **atopy**) and systemic response (called **anaphylaxis**).

Allergens

Allergens are foreign antigens that induce allergy. List of allergens is given in Table 16.2.

Experiments to Demonstrate Type I Reaction

Several experiments were conducted in the past to demonstrate type I hypersensitivity reactions.

TABLE 16.1: Features of various types of hypersensitivity reactions

	Type I	Type II	Type III	Type IV
Immune response altered	Humoral	Humoral	Humoral	Cell mediated
Immediate or delayed	Immediate	Immediate	Immediate	Delayed
Duration between appearance of symptoms and antigen contact	2 to 30 minutes	5–8 hour	2–8 hours	24–72 hours
Antigen	Soluble	Cell surface bound	Soluble	Soluble or bound
Mediator	IgE	IgG	Ag-Ab complex	T_{DTH} cell
Effector mechanism	Mast cell degranulation	▪ ADCC ▪ Complement-mediated cytolysis	Complement activation and inflammatory response	Macrophage activation leads to phagocytosis or cell cytotoxicity
Desensitization to the allergen	Easy, but short lasting	Easy, but short lasting	Easy, but short lasting	Difficult, but sustained
Typical manifestations	▪ Anaphylaxis ▪ Asthma ▪ Atopic dermatitis	▪ Transfusion reactions ▪ Rh incompatibility ▪ Hemolytic anemia	▪ Arthus reaction ▪ Serum sickness ▪ Glomerulonephritis ▪ Rheumatoid arthritis	▪ Tuberculin test ▪ Granuloma formation in tuberculosis, leprosy, etc ▪ Contact dermatitis

TABLE 16.2: Common allergens associated with type I hypersensitivity reaction

Allergen types	Examples
Food	Nuts, egg, peas, sea food, beans, milk
Plants and pollens	Rye grass, rag weed
Proteins	Foreign serum, vaccines
Drugs	Penicillin, sulfonamides, local anesthetics and salicylates
Insect bite products	Venom of bee, wasp, ant, cockroach calyx and dust mites
Others	Mold spores, animal hair and dander

P–K Reaction

K Prausnitz and H Kustner (1921) injected serum from an allergic person into a nonallergic individual intradermally. Later when the appropriate antigen was injected at the same site, a wheal and flare reaction (analogous to hives) developed at the site. Thus, they were the first to demonstrate that antibodies in the serum are responsible for the allergy and it is transferable from one person to another.

- The wheal and flare response occurs in three stages as follows:
  1. Begins with the appearance of an erythematous area at the site of injury, followed by
  2. Development of a flare (erythema) surrounding the site
  3. Finally, a wheal (swelling and congestion) forms at the site as fluid leaks under the skin from the surrounding capillaries.
- They named the response as the **P–K reaction** and such serum factors that reacted with the allergen were called **P–K antibodies**, or **reaginic antibodies**. After the discovery of IgE (K. Ishizaka, 1960), it became clear that these serum factors are nothing, but IgE antibodies.

Schultz Dale Phenomenon

This was done to demonstrate anaphylaxis in vitro; by exposing isolated tissues such as intestine or muscle segments of sensitized guinea pigs to the allergens.

Theobald Smith Phenomenon

This was done to demonstrate anaphylaxis *in vivo* by injecting the allergen into guinea pigs.

Mechanism of Type I Hypersensitivity

Type I hypersensitivity reaction occurs through two phases; the sensitization and effector phases, both occurring with an interval of 2–3 weeks (Fig. 16.1).

Sensitization Phase

This occurs when an individual is exposed for the first time to the sensitizing or priming dose of an allergen.

- Sensitization is most effective when the allergen is introduced parenterally, but may occur by any route, including ingestion or inhalation.
- In susceptible individuals, very minute doses can be sufficient to sensitise the host.
- The allergen is processed by the antigen presenting cells and the antigenic peptides are presented to the CD4 helper T cells.

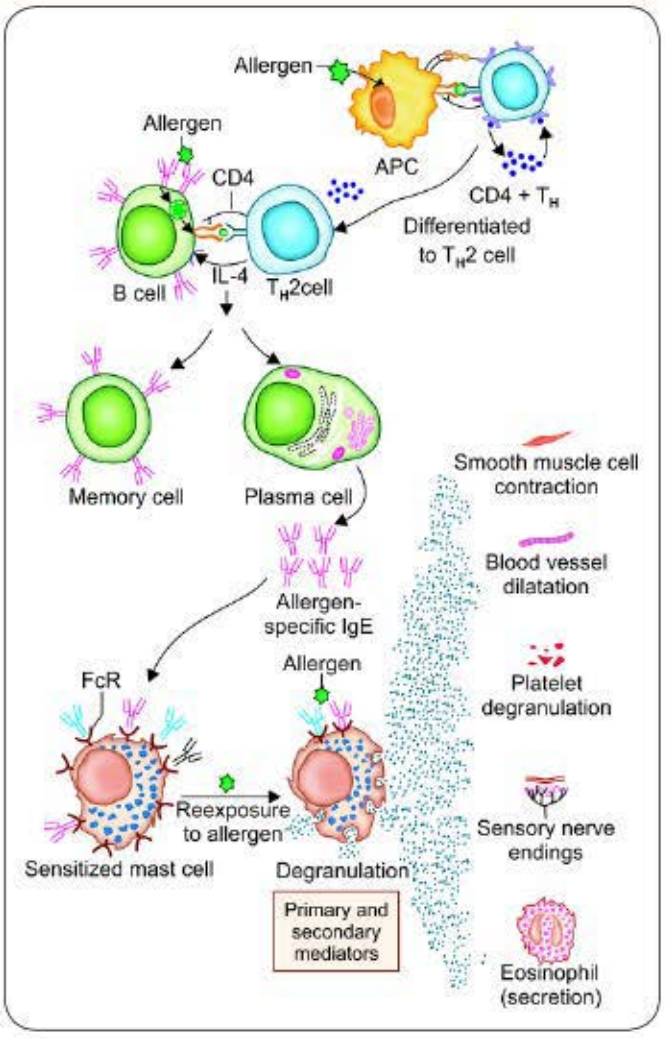

Fig. 16.1: Mechanism of type I hypersensitivity reaction

- Activated T_H cells are differentiated into T_H2 cells which in turn secrete interleukin 4 (IL-4).
- IL-4 induces the B cells to differentiate into IgE producing plasma cells and memory cells.
- Secreted IgE migrate to the target sites, and coat on the surface of mast cells and basophils. Fc region (the C_H3 and C_H4 domains) of IgE binds to high affinity Fc receptors (e.g. FcεR1) present on mast cell surface.
- Such sensitized mast cells (coated with IgE) will be waiting for interaction with the subsequent antigenic challenge.

Effector Phase

When the same allergen is introduced subsequently (shocking dose), it directly encounters with the Fab region of IgE coated on mast cells.

- IgE Cross linkage initiates degranulation: Allergen bound to IgE triggers the mast cells (and basophils) activation and degranulation. Granules in turn release a number of pharmacologically active chemical mediators that lead to the various manifestations of type-1 reaction.
- The memory B cells further differentiate into plasma cells that supply the IgE.
- **Degranulation in two phases**: Mast cells and basophils undergo degranulation in two phases.
  1. Primary mediators: The preformed chemical mediators which are already synthesized by mast cells, are immediately released, e.g. histamine and serotonin (Table 16.3).
  2. Secondary mediators: They are those where the mast cells synthesize and release, e.g. prostaglandins and leukotrienes (Table 16.3).
- **Pharmacological actions:** The chemical mediators perform several pharmacological actions, such as ↑bronchial and other smooth muscle contraction, ↑increased vascular permeability and vasodilation (Table 16.3).
- **Symptoms:** These actions in combinations, produce symptoms such as breathlessness, hypotension and shock leading to death at times.

TABLE 16.3: Mediators of type I hypersensitivity

Primary mediators	Action
Histamine, heparin and serotonin	↑Vascular permeability ↑Smooth-muscle contraction
Eosinophil chemotactic factor (ECF-A)	Eosinophil chemotaxis
Neutrophil chemotactic factor (NCF-A)	Neutrophil chemotaxis
Proteases	Bronchial mucous secretion Degradation of blood-vessel and basement membrane
Secondary mediators	**Action**
Platelet-activating factor	Platelet aggregation and degranulation; Contraction of pulmonary smooth muscles
Leukotrienes (slow reactive substance of anaphylaxis, SRS-A)	↑Vascular permeability; contraction of pulmonary smooth muscles
Prostaglandins	↑Vasodilation; Contraction of pulmonary smooth muscles Platelet aggregation
Bradykinin	↑Vascular permeability; smooth-muscle contraction
Cytokines (IL-1 and TNF-α)	Systemic anaphylaxis; ↑ Expression of cell adhesion molecules (CAMs) on venular endothelial cells

Manifestations of Type I Reaction

Manifestations are grouped into immediate and late.

Immediate Manifestations

Systemic Anaphylaxis

It is an acute medical emergency condition, characterized by severe dyspnea, hypotension, and vascular collapse leading to death at times.

- It occurs within minutes of exposure to allergen and unless treated promptly, may lead to fatality.
- Allergens: Wide range of allergens have been shown to trigger anaphylaxis in susceptible humans, including the venom (from bee, wasp, and ant stings); drugs (such as penicillin, insulin), antitoxins, seafood and nuts.
- Epinephrine (adrenalin) is the drug of choice for systemic anaphylactic reactions.

Localized Anaphylaxis (Atopy)

Here, the reaction is limited to a specific target tissue or organ, mostly the epithelial surfaces at the entry sites of allergen. These allergies afflict more than 20% of people. They almost always run in families (i.e. inherited) and are collectively called **atopy**. Examples include:

- **Allergic rhinitis (or hay fever):** It is the most common atopic disorder, affecting 10% of the population. This results from exposure to airborne allergens with the conjunctiva and nasal mucosa leading to appearance of various symptoms such as ↑watery secretions of the conjunctiva, nasal mucosa, and upper respiratory tract, as well as sneezing and coughing.
- **Asthma**: It is the second most common atopic manifestation. It differs from hay fever in involvement of lower respiratory mucosa, resulting in contraction of the bronchial smooth muscles and airway edema, ↑mucus secretion; all together leading to bronchoconstriction and dyspnea. The stimulus may or may not be an allergen. Accordingly, asthma can be classified as:
  - Allergic asthma: It is induced by airborne or blood-borne allergens, such as pollens, dust, fumes, insect products, or viral antigens.
  - Intrinsic asthma: It is independent of allergen stimulation; induced by exercise or cold.
- **Food allergy:** Various foods also can induce localized anaphylaxis in atopic individuals. The food allergens (e.g.nuts, egg, sea food, etc.) can either stimulate the mast cells lining gut mucosa to cause GI symptoms such as diarrhea and vomiting or may be carried in the blood stream to distant sites (e.g. when the allergen is deposited on skin, causes local wheal and flare like reaction called **atopic urticaria** (or hives).
- **Atopic dermatitis (allergic eczema):** It is an inflammatory disease of skin that is frequently associated with young children with family history of atopy. It often develops during infancy, manifested as erythematous skin eruptions which are filled with pus.The skin lesions have an increased response of T_H2 cells and eosinophils.
- **Drug allergy:** Various drugs (such as penicillin, sulphonamides, etc.) may produce type I hypersensitivity responses which may be either local reactions or even sometimes produce systemic anaphylaxis.

Late Manifestations

The immediate phase of type 1 reaction is followed, 4–6 hours later, by an inflammatory response. This phase lasts for 1–2 days and leads to tissue damage.

- **Mediators:** They released in acute phase along with cytokines (IL-3, IL-5, IL-8) and ECF and NCF induce recruitment of various inflammatory cells, such as neutrophils, eosinophils, macrophages, and lymphocytes, etc. Among the infiltrates, eosinophils and neutrophils predominate; each accounting for 30% of the total inflammatory cells influx.
- **Eosinophil influx:** It is favored by ECF (eosinophil chemotactic factor), IL-5 and GM-CSF. Eosinophils express Fc receptors for IgG and IgE and thus bind directly to antibody-coated allergens. This in turn causes release of toxic granules from eosinophils which contribute to the chronic inflammation of the bronchial mucosa that characterizes persistent asthma.
- **Neutrophil infiltration:** It is induced by NCF (neutrophil chemotactic factor), and other cytokines such as IL-8. Activated neutrophils release various mediators which further potentiates inflammatory tissue damage and thickening of basement membrane.

Factors Influencing Type I Hypersensitivity

1. Genetic Makeup

Host genetic factors play an important role in mounting an immune response against an allergen.

- Some individuals mount a normal response where as some mount an exaggerated immune response. Allergen to one individual may not be allergic to other individual.
- There are several gene loci identified which encode proteins that are involved in the regulation of immune responses towards the allergens.
- It is also observed that if both the parents are allergic there is 50% chance that the child will be allergic and when only one parent is allergic, the chance of the child being allergic drops down to 30%.

2. Allergen Dose

The dose of the allergen has a definite impact on the type of immune response produced. It is observed that repeated

small doses of allergen induce a persistent IgE response in mice; while higher dosage leads to transient IgE response with a shift towards IgG response.

3. T_H1 vs T_H2 Response

The balance between T_H1 and T_H2 response determines the response of an individual towards an allergen.

- T_H1 response produces cytokine interferon-γ, which is inhibitory to type I hypersensitivity; whereas T_H2 response induced cytokine IL-3, IL-4 and IL-5 promotes IgE mediated allergic response.
- Hence, accordingly atopic and non-atopic individuals would demonstrate a predominant T_H1 and T_H2 response to an allergen respectively.

Detection of type I hypersensitivity

Skin Prick Test

Small amounts of suspected potential allergens are introduced at different skin sites either by intradermal injection or by superficial scratching.

- If a person is already sensitized to the allergen, a local wheal and flare response develops within 30 minutes at the inoculation sites (Fig. 16.2).
- Advantage: Skin test is relatively inexpensive and allows screening of a large number of allergens at one go.
- Disadvantage: It may occasionally sensitize the individual to new allergens and in some rare cases may induce late-phase reaction or even systemic anaphylactic shock.

Radioimmunosorbent Test (RIST)

It quantitatively detects the **total serum IgE** antibody up to nanogram levels.

- It is a highly sensitive technique, based on the radioimmunoassay.
- The patient's serum (containing IgE) is made to react with agarose beads or paper disks coated with anti-IgE. After the beads or disks are washed, radiolabeled anti-IgE is added.
- The radioactivity of the beads or disks, measured with a gamma counter, is proportional to the level of IgE in the patient's serum (Fig. 16.3A).

Radioallergosorbent Test (RAST)

It is an another method similar to RIST, but it quantifies the serum level of **allergen specific IgE**.

- Here, instead of anti-IgE, the allergen itself is coated to beads or disks, so that when the patient's serum is added, only the allergen specific IgE would bind to the beads or disks.
- After washing the unbound nonspecific IgE, the amount of allergen specific IgE is then measured by adding radiolabeled anti-IgE, followed by counting the bound radioactivity by a gamma counter (Fig. 16.3B).

TREATMENT — Type I hypersensitivity reaction

- **Avoidance of contact with known allergens:** The first and foremost step is identification and avoidance of contact with known allergens such as dusts, house pets, allergic food, etc. However, it is not practically possible to avoid all allergens especially air born allergens, such as pollens.
- **Hyposensitization:** Repeated exposure to increased subcutaneous doses of allergens can reduce or eliminate the allergic response to the same allergen.

Contd...

TREATMENT — Type I hypersensitivity reaction

- This occurs probably due to either (1) a shift of IgE response towards IgG or (2) a shift of T_H2 response towards T_H1 response, which secrete IFN-γ that in turn can suppress the IgE response.
- Here, the IgG acts as blocking antibody because it competes with IgE for binding to the allergen. The IgG-allergen immunocomplex can be removed later by phagocytosis.

- **Monoclonal anti-IgE:** Humanized monoclonal anti-IgE can bind and block the IgE; but useful only if the IgE is not already bound to high affinity Fc receptors.
- **Drugs:** Several drugs are useful in suppressing type 1 response through various mechanisms (Table 16.4).

TABLE 16.4: Drugs used in type I hypersensitivity

Drugs	Mechanism of action
Antihistamines	Block H1 receptors on target cells; hence antagonize the effects of histamine released
Epinephrine (adrenaline)	Stimulates cAMP production in mast cells; thereby prevents mast cell degranulation
Cortisone	Blocks conversion of histidine to histamine and stimulates cAMP levels in mast cells
Theophylline	Prolongs high cAMP levels in mast cells
Cromolyn sodium	Blocks Ca^{2+} influx into mast cells

TYPE II HYPERSENSITIVITY REACTION

In type II reactions, the host injury is mediated by **antibodies** (IgG or rarely IgM) which interact with various types of antigens, such as:

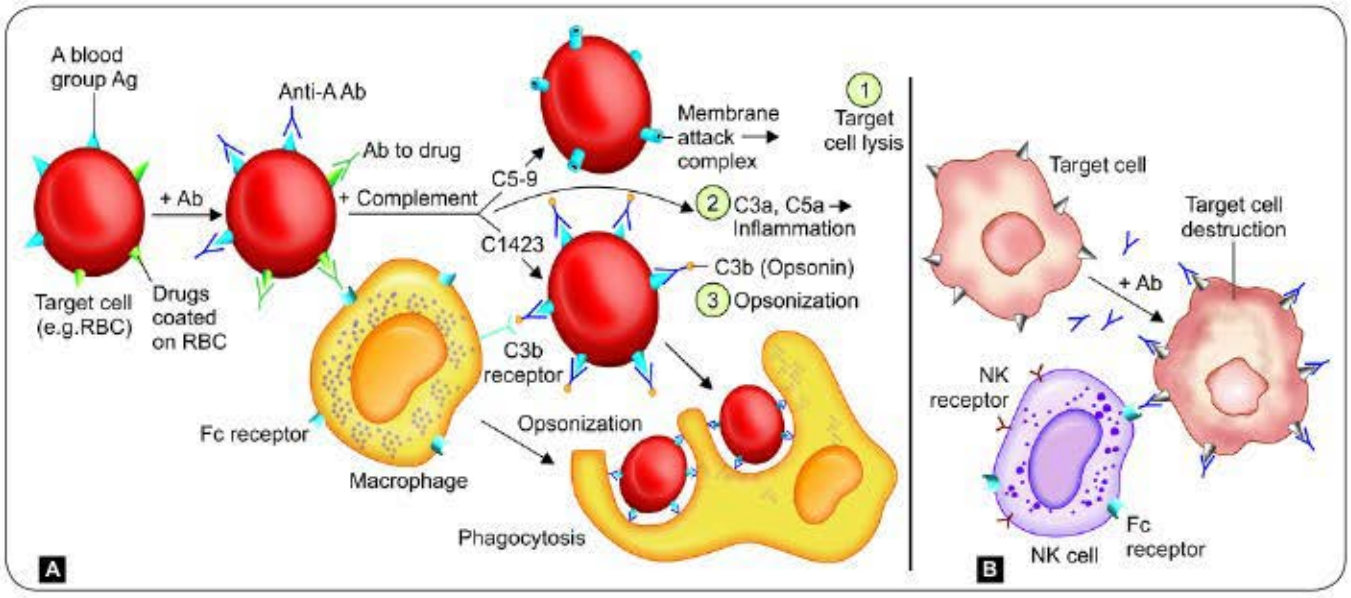
- Host cell surface antigens (e.g. RBC membrane antigens like blood group and Rh antigens)
- Extracellular matrix antigens or
- Exogenous antigens absorbed on host cells (e.g. a drug coating on RBC membrane).

After Ag-Ab binding occurs, the Fc region of antibody initiates the type II reactions by the following three broad mechanisms (Figs 16.4A and B).

Complement Dependent Reactions

The Fc region of antibody (bound with antigen) can activate the classical pathway of complement system. Activation of classical pathway leads to host cell injury which is mediated by the following three mechanisms (Fig. 16.4A).

1. **Complement dependent cytolysis:** The membrane attack complex (C5-C9) formed by the activation of classical pathway can produce pores which lead to lysis of the target cells.
2. **Complement dependent inflammation:** The by-product of complement pathways such as C3a and C5a are chemoattractants; hence can induce inflammatory response leading to tissue injury.
3. **Opsonization:** By-products of complement pathway, such as C3b and C4b act as opsonins. They deposit on the target cells. Phagocytes, such as macrophage



Figs 16.4A and B: Different mechanisms of antibody mediated type II hypersensitivity reactions. **A.** Complement-dependent reactions; **B.** Antibody-dependent cellular cytotoxicity (ADCC)

and neutrophil can engulf such C3b and C4b coated target cells via complement receptors.

Complement Mediated Type II Reactions

Antibody dependent complement mediated type II hypersensitivity is observed in various clinical conditions such as:

- **Transfusion reaction (ABO incompatibility):** RBCs from an incompatible donor are destroyed after being coated with recipient antibodies directed against the donor's blood group antigens (Fig. 16.4A).
- **Erythroblastosis fetalis (Rh incompatibility):** Rh negative mother having anti-Rh antibodies due to prior exposure to Rh positive blood (due to previous pregnancy or blood transfusion), can cross the placenta and cause destruction of Rh-positive fetal RBCs.
- **Autoimmune hemolytic anemia, agranulocytosis, or thrombocytopenia:** All these result due to production of autoantibodies to individual's own membrane antigens of RBCs/ granulocytes/platelets respectively.
- **Drug-induced hemolytic anemia:** Drug or its metabolic products may get adsorbed onto RBC membrane. If antibodies are formed against the drug, these antibodies will bind with the adsorbed drug on RBC surface and lead to complement activation and lyses of RBCs. For example, following quinine therapy used for malaria (resulting in black water fever) and penicillin therapy (Fig. 16.4A).
- **Pemphigus vulgaris** (autoantibodies against desmosomal proteins that lead to disruption of epidermal intercellular junctions).

Antibody Dependent Cellular Cytotoxicity (ADCC)

IgG antibodies can coat on the target cells by interacting with the surface antigens through Fab region. The Fc portion of IgG in turn binds to Fc receptors on various effector cells such as NK cells which result in destruction of the target cells (Fig. 16.4B).

- ADCC is involved in destruction of the targets that are too large to be phagocytozed, e.g. parasites, tumors or graft rejection.
- Although ADCC is typically mediated by IgG antibodies, in certain instances (e.g. eosinophil-mediated killing of parasites) IgE antibodies are used.

Autoantibody Mediated (Antibody-dependent Cellular Dysfunction or ADCD)

In this condition, the host produces certain autoantibodies which bind and disturb the normal function of human self-antigens.

- **Anti-receptor Ab:** Antibodies may be directed against human receptors, resulting in either inhibition or excessive activation of the receptors leading to host injury.
  - **Activation of receptor, e.g. Graves' disease:** Here, the autoantibodies produced are called LATS (long acting thyroid stimulators), which stimulate the thyroid cells to upregulate the production of thyroid hormones.
  - **Inhibition of receptor, e.g. myasthenia gravis:** In this condition, anti-acetyl choline (ACh) receptor antibodies are produced; which block the ACh receptors, leading to profound muscular weakness.
- **Other examples of ADCD:**
  - Good pasture syndrome (antibody produced against type IV collagen).
  - Pernicious anemia (antibody directed against intrinsic factor).
  - Rheumatic fever (antibody against streptococcal antigens cross reacting with heart).
  - Myocarditis in Chagas disease.

TYPE III HYPERSENSITIVITY REACTION

Type III hypersensitivity reactions are as a result of excess formation of immune complexes (Ag-Ab complexes) which initiate an inflammatory response through activation of complement system leading to tissue injury (Fig. 16.5).

- **Antigen involved:** Immune complexes can involve exogenous antigens such as bacteria and viruses or endogenous antigens such as DNA.

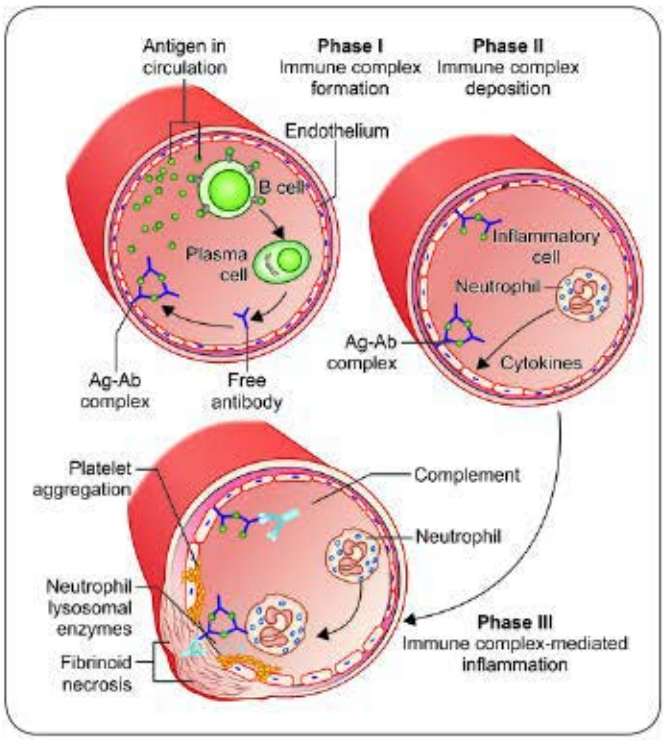


Fig. 16.5: Mechanism of systemic type III hypersensitivity reaction

- **Removal of immune complexes:** Mere formation of immune complexes does not result in type III hypersensitivity reaction.
  - Under normal circumstances, the immunocomplexes are rapidly cleared by activation of complement system.
  - Immunocomplexes coated with complements are either directly phagocytosed by macrophages/monocytes or are bound to RBCs and carried to liver and spleen where they are phagocytosed.
- However, in some situations, the immune system may be exposed to excess dose of antigen over long period of time such as in chronic infection, autoimmune diseases, and repeated exposure to environmental pollutants. This leads to formation of excessive immune complexes.

Soluble vs Insoluble Immunocomplexes

Balance between level of antigen and antibody decides the nature of immunocomplex that is going to be formed.

- In case of antibody excess or antigen-antibody equivalence, immune complexes formed are large and insoluble; which tend to localize near the site of antigen administration to produce a localized type III reaction.
- However, in situations when the antigen is in excess (particularly monovalent antigens), small soluble complexes are formed which tend to travel through blood and get deposited in various sites producing a generalized type III reaction.

Mechanism of Tissue Injury

Classical Complement Activation

The Ag-Ab-immune complexes stimulate the classical pathway of complement; the products of which mediate the tissue injury in type III reaction.

- **Anaphylatoxin:** Complement by-products C3a and C5a being anaphylactic; induce localized mast cell degranulation with consequent increase in vascular permeability.
- **Chemoattractant:** C3a and C5a also act as chemoattractants, causing recruitment of neutrophils to the site of immune complex deposition.
- **Role of neutrophils:** Neutrophils attempt to phagocytose the large immune complexes, but fail in doing so. Instead, they release large number of lytic enzymes from the secretory granules (through **frustrated phagocytosis**) which causes extensive tissue damage.

Platelet Activation

Immunocomplexes bind to the Fc receptors on platelets leading to their activation. Platelet aggregation (leads to microthrombi formation) and vasoactive amines released from activated platelets, both together cause tissue ischemia leading to further tissue damage.

Activation of Hageman Factor

Activation of Hageman factor leads to activation of kinin, which in turn causes causes vasodilatation and edema.

Types of Type III Hypersensitivity Reaction

Type III reactions are either localized or generalized.

Localized or Arthus Reaction

Arthus reaction is defined as localized area of tissue necrosis due to vasculitis resulting from acute immune complex deposition at the site of inoculation of antigen.

The reaction is produced experimentally (NM Arthus, 1903) by injecting an antigen into the skin of a previously immunized animal, e.g. rabbit (i.e. excess of preformed antibodies against the injected antigen are already present in the circulation). The circulating antibodies bind with the antigen in the dermis and form immune complexes. These immune complexes fix the complement, resulting in localised immune complex mediated inflammatory response called **Arthus reaction**.

In humans, localized Arthus reaction is seen in some situations, such as:

- **In skin:** (1) following insect bites or (2) during allergic desensitization treatment wherein repeated injections of the same antigen is given for long periods.
- **In lungs**, following inhalation of bacteria, fungi, spores or proteins may produce intrapulmonary lesions. Examples include conditions causing extrinsic allergic alveolitis, such as:
  - Farmer's lung: It develops following inhalation of actinomycetes (*Saccharopolyspora* species) from mouldy hay.
  - Bird-Fancier's disease: This develops following inhalation of serum proteins in dust derived from dried pigeon's feces.

Generalized or Systemic Type III Reactions

The pathogenesis of systemic immune complex disease can be divided into two phases:

1. **Formation of small sized soluble Ag-Ab complexes** in the circulation, which occurs following the entry of a large dose of antigen into the body.
2. **Induces inflammatory reaction:** Deposition of the immune complexes in various tissues, thus initiating an inflammatory reaction in various sites throughout the body such as; blood vessels (vasculitis), glomerular basement membrane (glomerulonephritis), and synovial membrane (arthritis). This has been linked to the pathogenesis of various diseases (Table 16.5).

Serum Sickness

This is another historical example of type III reaction. This condition is not seen now days, it was seen in the past,

TABLE 16.5: Diseases associated with generalized type III hypersensitivity reactions

Connective tissue disorders: Due to autoantibodies forming immunocomplexes with self-antigens ▪ SLE (systemic lupus erythematosus): Anti-DNA Ab ▪ Rheumatoid arthritis: Ab against human immunoglobulin ▪ PAN (polyarteritis nodosa)
Parasitic diseases: Resulting from immunocomplex deposition ▪ Nephrotic syndrome in *Plasmodium malariae* ▪ Katayama fever in schistosomiasis ▪ African trypanosomiasis
Bacterial diseases: Resulting from immunocomplex deposition ▪ *Streptococcus pyogenes*: Post-streptococcal glomerulonephritis ▪ *Mycobacterium leprae* (Lepra reaction type 2)
Viral diseases: With immunocomplex deposition ▪ Hepatitis B (arthritis) ▪ Hepatitis C (arthritis) ▪ Infectious mononucleosis (Epstein-Barr virus) ▪ Dengue (arthritis)
Others ▪ Hyperacute graft rejection ▪ Subacute bacterial endocarditis ▪ Serum sickness

following serum therapy, i.e. administration of foreign serum, e.g. horse anti-tetanus serum, to treat tetanus cases.

- The horse serum proteins being foreign can induce antibody formation in the host, leading to formation of large number of immunocomplexes
- Typically, after 7–8 days, the individuals begin to show various manifestations which are collectively called **serum sickness**. The symptoms include fever, weakness, vasculitis, edema, erythema and rarely lymphadenopathy and glomerulonephritis.
- It subsides gradually once the immunocomplexes are cleared and free antibodies accumulate.

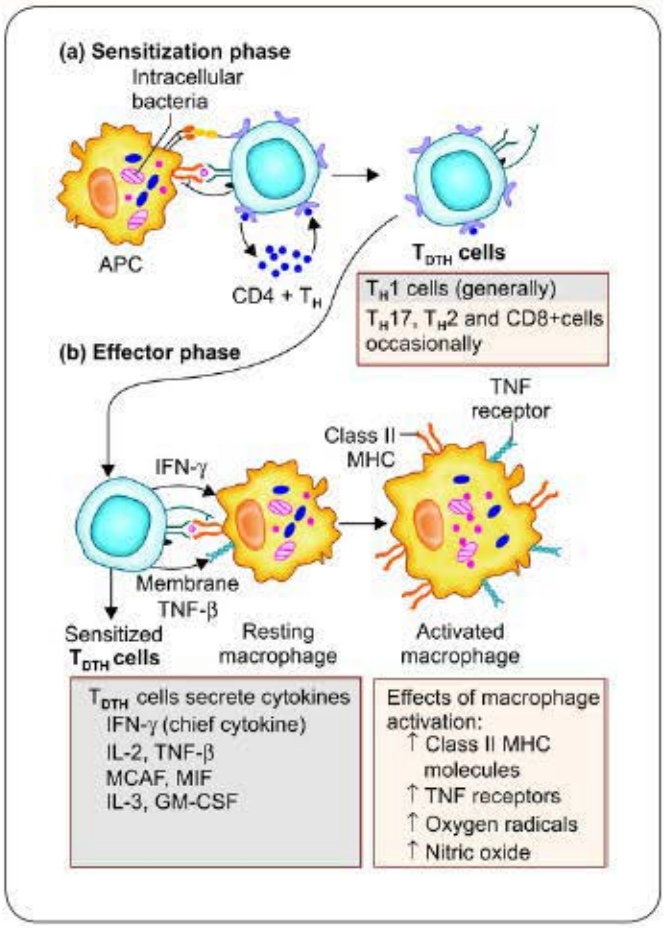
TYPE IV HYPERSENSITIVITY REACTION

Type IV hypersensitivity reactions differ from other types in various ways:

- It is delayed type (occurs after 48–72 hours of antigen exposure)
- It is cell-mediated; characteristic cells called **T_{DTH} cells** (delayed type of hypersensitivity T cells) are the principal mediators of type IV reactions.
- Tissue injury occurs predominantly due to activated macrophages.

Mechanism of Type IV Reactions

Type of IV hypersensitivity reactions occur through two phases—1. sensitization and 2. effector phases (Figs 16.6A and B).



Figs 16.6A and B: Mechanism of delayed type hypersensitivity. **A.** Sensitization phase; **B.** Effector phase

Abbreviations: APCs, antigen presenting cells; MHC, major histocompatibility complex; TNF, tumor necrosis factor; IFN, interferons; DTH, delayed type hypersensitivity; MCAF, monocyte chemotactic and activating factor; MIF migration inhibitory factor

Sensitization Phase

This is the initial phase of 1–2 weeks occurring following antigenic exposure (Fig. 16.6A).

- During this period, the antigen presenting cells (APCs) process and present the antigenic peptides along with MHC-II to the helper T cells. T_H cells are differentiated to form T_{DTH} cells.
- Most T_{DTH} cells are derived from T_H1 cells; but occasionally other T cells, such as $CD8^+$ T cells and $CD4^+$ T_H17 can also act as T_{DTH} cells.

Effector Phase

The T_{DTH} cells, on subsequent contact with the antigen, secrete variety of cytokines which attract and recruit various inflammatory cells (e.g. macrophages) at the site of DTH reaction (Fig. 16.6B).

Cytokines Secreted from T_{DTH} Cells

- **Interferon-γ:** It is the key cytokine of type IV reaction. It activates the resting macrophages into activated macrophages which are highly competent for microbial killing; mediated through several mechanisms such as:
  - ↑Expression of MHC-II molecules so that they can act as efficient APCs
  - ↑ TNF receptors
  - ↑ Levels of oxygen radicals and nitric oxide
- **Interleukin-2 (IL-2):** It acts in autocrine manner; stimulates the proliferation of T_{DTH}cells.
- **MCAF** (Monocyte chemotactic and activating factor) and **TNF** β–Help in migration of monocytes from blood to the site of DTH and transforming them into tissue macrophages.
- **MIF** (migration inhibitory factor): It further inhibits migration of macrophages from the site of DTH.
- **IL-3** and **GM-CSF** (granulocyte-monocyte colony stimulating factor)-help in local synthesis of monocytes.

Role of DTH: Protective vs Tissue Damage Response

Through type IV hypersensitivity reactions, host attempts to provide defense against many intracellular microorganisms such as *M. tuberculosis* as well as several chemicals and nickel salts (Table 16.6). Always, the attempts do not result in protection.

TABLE 16.6: Examples of DTH

Intracellular pathogens inducing DTH	
Intracellular bacteria ▪ *Mycobacterium leprae* ▪ *M. tuberculosis* ▪ *Listeria monocytogenes* ▪ *Brucella abortus*	**Intracellular fungi** ▪ *Pneumocystis jirovecii* ▪ *Candida albicans* ▪ *Histoplasma capsulatum* ▪ *Cryptococcus neoformans*
Intracellular viruses ▪ Herpes simplex virus ▪ Variola (smallpox) ▪ Measles virus	**Skin test to demonstrate DTH** ▪ Tuberculin test (Mantoux test) ▪ Lepromin test ▪ Montenegro test (leishmaniasis) ▪ Frie test—done in LGV
Contact dermatitis	
Following exposure to contact antigens— Nickel, poison ivy, poison oak, picryl chloride	
Other examples of DTH	
Noninfectious conditions ▪ Diabetes mellitus type 1 ▪ Multiple sclerosis ▪ Peripheral neuropathies ▪ Hashimoto's thyroiditis	 ▪ Crohn's disease ▪ Chronic transplant rejection ▪ Graft-versus-host disease
Granuloma formation seen in Tuberculosis, sarcoidosis, schistosomiasis and other trematode infections	**Other example** Lepra reaction type I

Protective Response

Under normal circumstances, the pathogens are usually cleared with little tissue damage; mediated by the enhanced microbicidal potency of activated macrophages.

Tissue Damage Response

However, in conditions, when the intracellular microbes escape the macrophage killing mechanisms; the enhanced phagocytic activity and release of various lytic enzymes by the activated macrophages in an attempt to kill the pathogen leads to non specific tissue destruction.

Pathology of DTH Reaction (Granuloma Formation)

Continuous DTH reaction for killing the intracellular microbes (especially persistent and/or nondegradable antigens) leads to formation of granuloma (e.g. tubercles in leprosy and tuberculosis).

- The initial T_H cell infiltrate is progressively replaced by macrophages in 2–3 weeks. Macrophages transform into two type of cells:
  1. They become large, flat, and eosinophilic; denoted as **epithelioid cells**.
  2. The epithelioid cells occasionally fuse (induced by IFN-γ) to form **multinucleated giant cells**.

Granuloma consists of an inner zone of epithelioid cells, typically surrounded by a collar of lymphocytes and a peripheral rim of fibroblasts and connective tissue (Fig. 16.7).

Tuberculin Test

Tuberculin test is the prototype of delayed hypersensitivity. In sensitized individuals, (i.e. who possess sensitized T_{DTH}

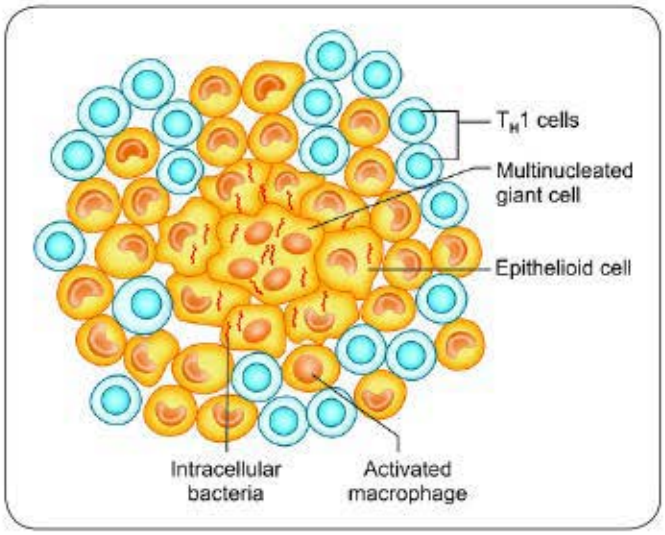


Fig. 16.7: Structure of granuloma

cells due to prior contact with *M. tuberculosis*); when a preparation of tuberculin antigen (glycerol extract of the tubercle bacillus) is injected intradermally, a local reaction develops after 48–72 hours consisting of induration surrounded by erythema.

Contact Dermatitis

Many antigens such as nickel, poison oak, etc. (Table 16.6) act by producing DTH response:

- Most of these substances are haptens; they complex with skin proteins, which act as carrier to make the haptens immunogenic.
- This hapten-skin protein complex is internalized by skin APCs (e.g. Langerhans cells), then presented to T_H cells to induce a TDH reaction.
- Activated macrophages release lytic enzymes which result in skin lesions (e.g. redness and pustule seen following contact with poison oak).

EXPECTED QUESTIONS

I. Essay:

1. Define hypersensitivity reaction. Classify hypersensitive reactions. Write in detail about type IV hypersensitive reaction.
2. Neha, a seventeen year student who has recently joined MBBS, has come back to the hostel after returning from the first vacation to home. After entering to her hostel room, she suddenly developed an episode of severe sneezing, and dyspnea. She had to be admitted to the casualty and when asked, she told that she has faced similar episodes since her child childhood.
   a. What type of immune reaction is this?
   b. Describe the pathogenesis of this condition and management.

II. Write short notes on:

1. Type II hypersensitive reaction
2. Immune complex mediated hypersensitive reaction
3. Delayed type hypersensitive reaction

III. Multiple Choice Questions (MCQs):

1. Type I hypersensitivity is mediated by which of the following immunoglobulins?
a. IgA b. IgG
c. IgM d. IgE

2. Wheal and flare is which type of hypersensitivity reaction:
a. Type I b. Type II
c. Type IV d. Type V
e. Mediated through allergen specific IgE

3. Type I hypersensitivity includes all of the following except:
a. Autoimmune hemolytic anemia
b. Anaphylaxis
c. Extrinsic asthma
d. Hay fever

4. The type of Hypersensitivity reaction in Myasthenia gravis is:
a. Type I b. Type II
c. Type III d. Type IV

5. A positive tuberculin test is an example of:
a. Type I hypersensitivity
b. Type II hypersensitivity
c. Type III hypersensitivity
d. Type IV hypersensitivity

Answers

1. d **2.** a **3.** a **4.** b **5.** d

CHAPTER 17

Autoimmunity

Chapter Preview

- Immunological tolerance
- Mechanisms of autoimmunity
- Autoimmune diseases
- Single organ or cell type autoimmune diseases
- Systemic autoimmune diseases
- Laboratory diagnosis of autoimmune diseases

Autoimmunity is a condition in which the body's own immunologically competent cells or antibodies act against its self-antigens resulting in structural or functional damage. Paul Ehrlich had first introduced the concept of autoimmunity; he termed this condition as "horror autotoxicus".

- Normally immune system does not react to its own antigens due to a protective mechanism called tolerance. Any breach in tolerance mechanisms predispose to several autoimmune diseases.
- Therefore, before going into the details of mechanisms of autoimmunity; it is essential to know about the various tolerance mechanisms that the human immune system possesses.

IMMUNOLOGICAL TOLERANCE

Immunological tolerance is a state in which an individual is incapable of developing an immune response against his own tissue antigens. It is mediated by two broad mechanisms—central tolerance and peripheral tolerance.

Central Tolerance

This refers to the deletion of self-reactive T and B lymphocytes during their maturation in central lymphoid organs (i.e. in the thymus for T cells and in the bone marrow for B cells).

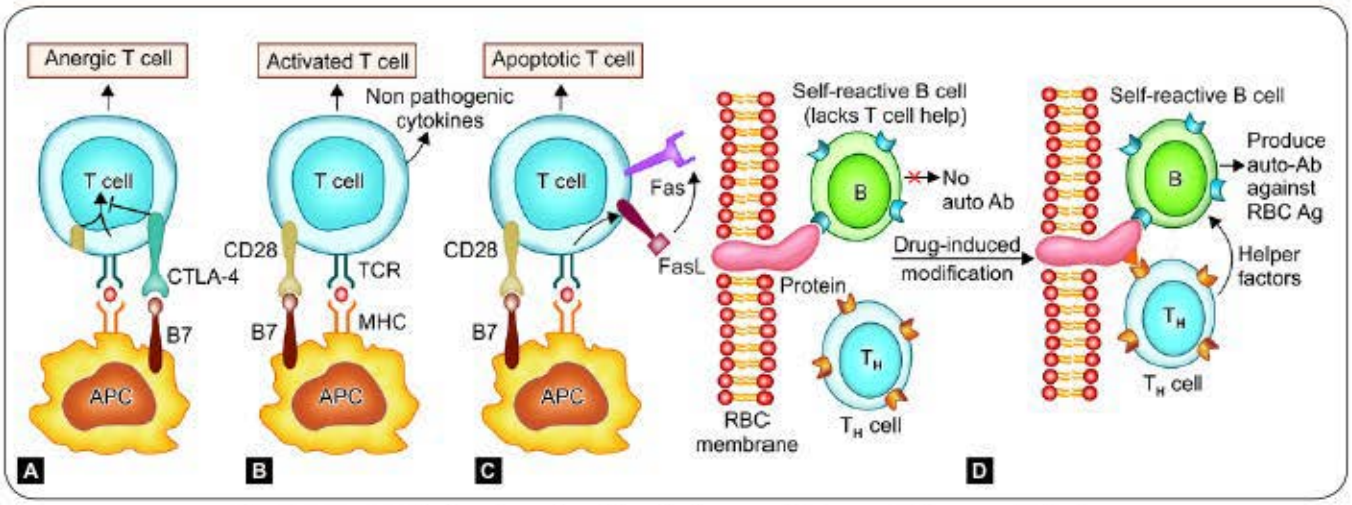
- **In thymus:** During the T cell development in thymus, if any self-antigens are encountered, they are processed and presented by thymic antigen presenting cells (APCs) in association with self-MHC. Any developing T cell that expresses a receptor for such self-antigen is negatively selected (i.e. deleted by apoptosis). Therefore, the resulting peripheral T-cell pool is devoid of self-reactive cells.
- **In bone marrow:** When developing immature B cells in the bone marrow encounter a self-antigen during their development, the tolerance is developed by:
  - **Receptor editing:** It is a process by which many of the B cells reactivate the machinery of antigen receptor gene rearrangement (mainly genes coding for light chains), so that a different (edited) B cell receptor will be produced which no longer recognizes the self-antigen.
  - **Negative selection:** After receptor editing, if the B cells again recognize a self-antigen, then they are destroyed by subjecting them to apoptosis.

However, the process of central tolerance is not completely perfect. Many self-reactive T and B cells bearing receptors for self-antigens escape into the periphery. Hence, for counteracting those lymphocytes, peripheral tolerance takes a lead role.

Peripheral Tolerance

This refers to several back-up mechanisms that occur in the peripheral tissues to counteract the self-reactive T cells that escape central tolerance. It is provided by several mechanisms (Fig. 17.1).

- **Ignorance:** The self-reactive T cells might never encounter the self-antigen which they recognize and therefore remain in a state of ignorance.
- **Anergy:** It can be defined as unresponsiveness to antigenic stimulus. The self-reactive T cells interact with the APCs presenting the self antigen, but the co-stimulatory signal is blocked. The B7 molecules on APC bind to CTLA-4 molecules on T cells instead of CD28 molecules (Fig. 17.1A).



Figs 17.1A to D: Mechanisms of peripheral tolerance. **A.** Anergy; **B.** Phenotypic skewing; **C.** Apoptosis; **D.** T cells help to stimulate self-reacting B cells

Note: Normally, T cell activation requires two signals- Main signal (provided by antigen MHC complex of APC interacts with TCR on T cell) and a co-stimulatory signal (B7 molecules on APCs bind to CD28 on T cells). If self antigens are processed and presented by APCs, that do not bear the co-stimulators, a negative signal is delivered, and the cell becomes anergic.

- **Phenotypic skewing:** Self-reactive T cells interacting with APCs presented with self-antigens, undergo full activation, but might secrete nonpathogenic cytokines and chemokine receptors profile, hence although they are activated, yet fail to induce autoimmune response (Fig. 17.1B).
- **Apoptosis by AICD:** Self-reactive T cells are activated after interacting with APCs presented with self-antigens. But the activation of T cells induces upregulation of Fas ligand which subsequently interacts with the death receptor Fas leading to apoptosis. This mechanism is called as activation-induced cell death (AICD) (Fig. 17.1C).
- **Regulatory T cells (T_{reg} cells):** T_{reg} cells can down regulate the self-reactive T cells through secreting certain cytokines (e.g., IL-10 and transforming growth factor β [TGF-β]) or killing by direct cell to cell contact.
- **Dendritic cells (DCs):** When certain dendritic cells such as immature DCs and tolerogenic DCs capture the self-antigen for processing, they down regulate the expression of molecules of costimulatory ligands such as CD40 and B7 molecules or act indirectly by induction of regulatory T cells.
- **Sequestration of self-antigen:** Certain self-antigens can evade immune recognition by sequestration in immunologically privileged sites, e.g. corneal proteins, testicular antigens and antigens from brain.

MECHANISMS OF AUTOIMMUNITY

Autoimmunity results due to breakdown of one or more of the mechanisms of immunological tolerance.

Breakdown of T Cell Anergy

Normal cells that do not usually express costimulatory molecules (B7) can be induced to do so. Such induction may occur in presence of tissue necrosis and local inflammation. This mechanism has been postulated for—

- Multiple sclerosis
- Rheumatoid arthritis
- Psoriasis.

Failure of AICD

Failure of the autoreactive activated T cells to undergo activation-induced cell death (AICD), i.e. apoptosis via Fas-Fas ligand can lead to autoimmunity. It is observed in patients suffering from systemic lupus erythematosus (SLE).

Loss of T_{reg} Cells

Autoimmunity can result following the loss of regulatory T cell-mediated suppression of self-reactive lymphocytes.

Providing T Cell help to stimulate self-reacting B Cells

Antibody response to self-antigens occurs only when potentially self-reactive B cells receive help from T cells. For example, in autoimmune hemolytic anemia, administration of certain drugs may result in drug-induced alterations in the red cell surface that create antigens which can be recognized by helper T cells (Fig. 17.1D).

Release of Sequestered Antigens

The sequestered antigens are usually viewed as foreign to the immune system as they are never been exposed to the tolerance mechanisms during development of immune system. Injury to the organs leads to release of such sequestered antigens which are very well capable of mounting an immune response. Spermatozoa and ocular antigens release can cause post vasectomy orchitis and post-traumatic uveitis.

Infectious agents may participate in the pathogenesis of autoimmunity by the following mechanisms:

Molecular Mimicry

Some microorganisms share antigenic determinants (epitopes) with self-antigens, and an immune response against such microbes would produce antibodies that can crossreact with self-antigen.

- For example, acute rheumatic fever results due to antibodies formed against streptococcal antigens (M protein), cross react with cardiac antigens (glycoproteins), due to antigenic cross reactivity.
- Molecular mimicry involving T-cell epitopes- Examples include multiple sclerosis, where T cell clones reacting to myelin basic protein probably would have been induced by reacting against peptides derived from many microbes including viruses.

Polyclonal Lymphocyte Activation

Several microorganisms and their products are capable of causing polyclonal (i.e. antigen-nonspecific) activation of T cells or B cells.

- **Polyclonal T cell activation:** Superantigens released from microbes (e.g. *Staphylococcus aureus*), polyclonally activate the T cells directly by binding to antigen non-specific Vβ region of T cell receptors.
- **Polyclonal B cell activation:** It can be induced by products of various microbes such as Epstein Barr virus, HIV, etc.

Exposure of Cryptic Self-epitopes

Research has proved that "molecular sequestration" of antigens is much more common than anatomic sequestration.

- During development of immune system, not all epitopes of an antigen are effectively processed and presented to T cells. There are some nondominant cryptic epitopes which remain sequestrated. Hence, T cell clones reacting against such epitopes are not deleted.
- Such cryptic self epitopes can be released secondary to inflammation at a site of tissue injury, which can induce increased protease production and differential processing of released self-epitopes by APCs.

Epitope Spreading

The self-peptides released due to persistent inflammation induce tissue damage (as occurs in chronic microbial infection) and are processed and presented by APCs along with microbial peptides. It is possible that, there may occur a shift or spread of T cell recognition to self epitopes presented on APCs rather than recognizing microbial epitope.

Bystander Activation

It is the nonspecific activation of bystander self-reactive T_H1 cells. Activation of microorganism-specific T_H1 cells leads to cytokine influx which causes an increased infiltration of various nonspecific T cells at the site of infection.

AUTOIMMUNE DISEASES

The immunological attack of self-reacting T lymphocytes or autoantibodies on tissues leads to the development of various autoimmune diseases. There are broad ranges of autoimmune diseases which can either be localized into single organ/cell type or may involve many organs and cause systemic manifestations (Table 17.1).

TABLE 17.1: Autoimmune diseases and immune response produced with their clinical manifestations

Single organ or cell type autoimmune diseases		
Disease	**Self-antigen present on**	**Type of immune response and Important features**
Autoimmune anemias		
Autoimmune hemolytic anemia	RBC membrane proteins	Autoantibodies to RBC antigens trigger complement mediated lysis or antibody-mediated opsonization of the RBCs
Drug-induced hemolytic anemia	Drugs alter the red cell membrane antigens	Drugs such as penicillin or methyldopa interact with RBCs so that the cells become antigenic
Pernicious anemia	Intrinsic factor (a membrane-bound protein on gastric parietal cells)	Autoantibodies to intrinsic factor block the uptake of vitamin B 12; leads to megaloblastic anemia
Idiopathic thrombocytopenic purpura	Platelet membrane proteins (glycoproteins IIb-IIIa or Ib-IX)	Auto-antibodies against platelet membrane antigens leads to ↓platelet count

Contd...

Contd...

Goodpasture syndrome	Renal and lung basement membranes	Auto-antibodies bind to basement-membrane antigens on kidney glomeruli and the alveoli of the lungs followed by complement mediated injury leads to progressive kidney damage and pulmonary hemorrhage
Myasthenia gravis	Acetylcholine receptors	Blocking type of autoantibody directed against Ach receptors present on motor nerve endings, leads to progressive weakening of the skeletal muscles
Graves' disease	Thyroid-stimulating hormone (TSH) receptor	Anti-TSH-autoantibody (stimulates thyroid follicles, leads to hyperthyroid state)
Hashimoto's thyroiditis	Thyroid proteins and cells	Autoantibodies and T_{DTH} cells targeted against thyroid antigen leads to suppression of thyroid gland. ▪ Seen in middle aged females ▪ Hypothyroid state is produced (↓ production of thyroid hormones)
Post-streptococcal glomerulonephritis	Kidney	Streptococcal antigen–antibody complexes are deposited in glomerular basement membrane
Systemic autoimmune diseases		
Disease	**Self-antigen present on**	**Type of immune response and Important features**
Systemic lupus erythematosus (SLE)	Autoantibodies are produced against various tissue antigens such as DNA, nuclear protein, RBC and platelet membranes.	▪ **Age and sex:** Women (20-40 years of age) are commonly affected; female to male ratio is 10:1. ▪ **Immune complexes** (self Ag-autoAb) are formed; which are deposited in various organs ▪ Major symptoms: Fever, **butterfly rash** over the cheeks, arthritis, pleurisy, and kidney dysfunction
Rheumatoid arthritis	Here, a group of auto-antibodies against the host IgG antibodies are produced called **RA factor**. It is an IgM antibody directed against the Fc region of IgG. Anticitrullinated peptide antibodies (**ACPA**) are also produced	▪ Age and sex: Women (40–60 years of age) affected ▪ Autoantibodies bind to circulating IgG, forming IgM-IgG complexes that are deposited in the joints and can activate the complement cascade. **Major symptoms:** ▪ Main feature: Arthritis (chronic inflammation of the joints, begins at synovium; most common joints involved are-small joints of the hands, feet and cervical spine) ▪ Other features: Hematologic, cardiovascular, and respiratory systems are also frequently affected
Sjögren syndrome	Ribonucleoprotein (RNP) antigens SS-A (Ro) and SS-B (La) present on salivary gland, lacrimal gland, liver, kidney, thyroid	Auto-antibodies to the RNP antigens SS-A (Ro) and SS-B (La); leads to immune-mediated destruction of the lacrimal and salivary glands resulting in dry eyes (*keratoconjunctivitis sicca*) and dry mouth (xerostomia)
Scleroderma (Systemic sclerosis)	Nuclear antigens such as DNA topoisomerase and centromere present in heart, lungs, GIT, kidney, etc.	Helper T cell (mainly) and auto-antibody mediated. Excessive fibrosis of the skin, throughout the body **Two types** ▪ Diffuse scleroderma: Autoantibodies against DNA topoisomerase I (anti-Scl 70) is elevated ▪ Limited scleroderma: ↑Anticentromere antibody, characterized by CREST syndrome—calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia
Seronegative spondyloarthropathies	Sacroiliac joints and other vertebrae Several types: ▪ Ankylosing spondylitis ▪ Reiter Syndrome ▪ Psoriatic Arthritis ▪ Spondylitis with Inflammatory Bowel Disease ▪ Reactive arthritis	**Common characteristics:** They present as rheumatoid arthritis like features, but differ from it by: ▪ Association with HLA-B27 ▪ Pathologic changes begin in the ligamentous attachments to the bone rather than in the synovium ▪ Involvement of the sacroiliac joints, and/or arthritis in other peripheral joints ▪ Absence of RA (hence the name "seronegative") ▪ Auto-Ab and immune complex mediated
Multiple sclerosis	Brain (white matter)	Self-reactive T cells produce characteristic inflammatory lesions in brain that **destroys the myelin** sheath of nerve fibers; leads to numerous neurologic dysfunctions

LABORATORY DIAGNOSIS OF AUTOIMMUNE DISEASES

Autoimmune diseases are diagnosed by detection of various autoantibodies in serum of the patients;

- **Autoimmune hemolytic anemias:** Diagnosed by Coombs test, in which the red cells are incubated with an anti-human IgG antiserum. If IgG autoantibodies are present on the red cells, the cells are agglutinated by the antiserum.
- **Goodpasture syndrome:** Biopsies from patients are stained with fluorescent-labeled anti-IgG and anti-C3b reveal linear deposits of IgG and C3b along the basement membranes.
- **SLE** is diagnosed by:
  - Detection of autoantibodies against various nuclear antigens by indirect immunofluorescence assay (most widely used) and ELISA based techniques.
    - **Antinuclear antibody (ANA):** Positive in >90% of cases, used as screening method (Fig. 17.2).
    - Anti-double stranded DNA (dsDNA): Highly specific, used for confirmation of cases.
    - Anti-Sm antibodies
  - **Lupus band test:** It is a direct immunofluorescence test, can detect deposits of immunoglobulins and complement proteins in the patient's skin.
  - **LE cell test:** The lupus erythematosus (LE) cell test was commonly used for diagnosis, but it is no longer used because the LE cells are only found in 50–75% of SLE cases.
- **Scleroderma:** Anti-Scl 70 antibody is raised, detected by indirect immunofluorescence assay.
- **Sjögren's syndrome:** Is diagnosed by detection of SS-A (or anti-Ro) and SS-B (or anti-La) antibodies by indirect immunofluorescence assay.

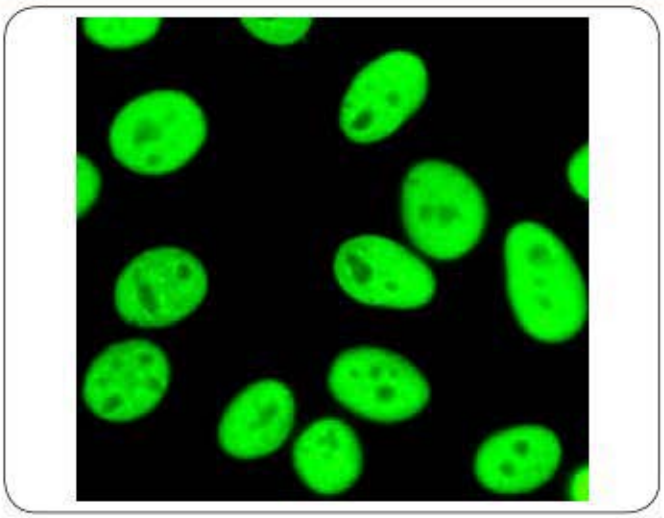


Fig. 17.2: Antinuclear antibody (homogeneous pattern) by indirect immunofluorescence staining

Source: Biological Reference Reagents, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Rheumatoid arthritis:** RA is diagnosed by detection of two important autoantibodies-RA factor and ACPA.
  - ***RA factor*** (by latex agglutination test): RA factor is an IgM autoantibody directed against Fc portion of IgG.
    - RA factor detection has good sensitivity (negative in only 15% of cases).
    - False positive detection of RA factor is seen in other autoimmune diseases.
  - ***Anticitrullinated peptide antibodies* (ACPA):** is an auto-antibody to citrullin protein. It is positive only in 67% of cases; but is *highly specific*.
  - ***Rose-Waaler test*** to detect RA factor is of historical importance, no longer used now.

EXPECTED QUESTIONS

I. Essay:

1. Define autoimmunity. Classify various autoimmune diseases and briefly explain various mechanisms involved in the development of autoimmunity with suitable examples.

II. Multiple Choice Questions (MCQs):

1. **Lens antigens of the eye are a type of:**
   a. Sequestered antigens
   b. Neoantigens
   c. Cross reacting antigens
   d. None of the above
2. **Autoimmunity can be caused due to all of the following except:**
   a. The pressure of forbidden clones
   b. Expression of cryptic antigens
   c. Negative selection of T- cells in the thymus
   d. Release of sequestered antigens
3. **All of the following are systemic autoimmune diseases except:**
   a. Hashimoto's thyroiditis
   b. Systemic lupus erythematosus
   c. Rheumatoid arthritis
   d. Scleroderma

CHAPTER 18

Immunodeficiency Disorders

Chapter Preview

- Definition and Classification
- Primary Immunodeficiency Diseases
  - Humoral Immunodeficiency (B Cell Defects)
  - Cellular Immunodeficiencies (T Cell Defects)
  - Combined Immunodeficiencies
  - Disorders of Phagocytosis
- Secondary Immunodeficiencies

DEFINITION AND CLASSIFICATION

Immunodeficiency is a state where the defence mechanisms of the body are impaired, leading to enhanced susceptibility to microbial infections as well as to certain forms of cancer.

Immunodeficiency diseases are broadly classified as primary or secondary.

- Primary immunodeficiency diseases result from inherited defects affecting immune system development.
- Secondary immunodeficiency diseases are secondary to some other disease process that interferes with the proper functioning of the immune system (e.g., infection, malnutrition, aging, immunosuppression, autoimmunity, or chemotherapy).

PRIMARY IMMUNODEFICIENCY DISEASES

Most primary immunodeficiency diseases are genetically determined and can be further classified into diseases resulting from deficiency of either specific immunity (i.e. humoral or cellular or both) or nonspecific host defense mechanisms (mediated by complement proteins and cells such as phagocytes or NK cells) (Table 18.1).

However, the distinction of diseases affecting specific immunity (humoral or cellular) components is not clearcut. In particular, T-cell defects almost always lead to impaired antibody synthesis, and hence isolated deficiencies of T cells are usually indistinguishable from combined deficiencies of T and B cells.

The type of infections in a given patient depends largely on the component of the immune system that is affected (Table 18.2).

TABLE 18.1: Classification of primary immunodeficiency diseases

Humoral immunodeficiency (B cell defects)
▪ Bruton disease (X-linked agammaglobulinemia)
▪ Common variable immunodeficiency
▪ Isolated IgA deficiency
▪ Hyper-IgM syndrome
▪ Transient hypogammaglobulinemia of infancy
Cellular immunodeficiencies (T cell defects)
▪ DiGeorge syndrome (thymic hypoplasia)
▪ Chronic mucocutaneous candidiasis
▪ Purine nucleoside phosphorylase (PNP) deficiency
Combined immunodeficiencies (B and T cell defects)
▪ Severe combined immunodeficiencies
• Cytokine receptor mutation
• Adenosine deaminase (ADA) deficiency
▪ Wiskott–Aldrich syndrome
▪ Ataxia telangiectasia
▪ Nezelof syndrome
Disorders of phagocytosis
▪ Chronic granulomatous disease
▪ Myeloperoxidase deficiency
▪ Chediak–Higashi syndrome
▪ Leukocyte adhesion deficiency
▪ Lazy leukocyte syndrome
▪ Job's syndrome or Hyper-IgE syndrome
▪ Tuftsin deficiency
▪ Shwachman's disease
Disorders of complement*
▪ Complement component deficiencies
▪ Complement regulatory protein deficiencies

*Described in detail in Chapter 13

TABLE 18.2: Examples of Infections in Immunodeficiencies

Pathogen type	T-cell defect	B-cell defect	Granulocyte defect	Complement defect
Bacteria	Bacterial sepsis	Streptococci staphylococci *Haemophilus influenzae*	Staphylococci *Pseudomonas, Nocardia*	*Neisseria* Other pyogenic infections
Viruses	Cytomegalovirus, Epstein–Barr virus, Severe varicella, Chronic infections with respiratory and intestinal viruses	Enterovirus encephalitis	—	
Fungi	*Candida,* *Pneumocystis jirovecii*	—	*Candida,* *Aspergillus*	
Parasites	—	Giardiasis	—	
Special features	Aggressive disease with opportunistic pathogens, failure to clear infections	Recurrent sinopulmonary infections, Sepsis, chronic meningitis	—	

- Patients with defects in humoral immunity, complement, or phagocytosis typically suffer from recurrent infections with pyogenic bacteria
- On the other hand, those with defects in cell-mediated immunity are prone to infections caused by viruses, fungi, and intracellular bacteria.

Most primary immunodeficiencies come to attention early in life (between 6 months and 2 years of life); usually because of the susceptibility of infants to recurrent infections.

HUMORAL IMMUNODEFICIENCY (B CELL DEFECTS)

Bruton Disease (X-linked Agammaglobulinemia)

Bruton disease is one of the more common forms of primary immunodeficiency. It is characterized by:

- Failure of pre-B cells to differentiate into immature B cells in the bone marrow—due to absence of an enzyme called **Bruton's tyrosine kinase** which is involved in transformation of pre-B cell into immature B cell.
- As a result, there occurs total absence of B cells and plasma cells in the circulation, with depressed serum levels of all classes of immunoglobulins. However, Pre-B cells are found in normal numbers in bone marrow and the T-cell-mediated responses are also normal.
- The B-cell maturation stops at pre B cell stage; after the synthesis of heavy-chain without forming the light chains. Hence the cytoplasm of pre B cell may have incomplete immunoglobulins.
- Bruton's tyrosine kinase is X-linked; hence, this disease is seen primarily in males; nevertheless, sporadic cases have been described in females.
- Secondary infections are seen after 6 months of age, when maternal antibodies are depleted, such as:
  - Recurrent bacterial infections caused by pathogens that are usually cleared by antibody opsonization (e.g., *Haemophilus influenzae, Streptococcus pneumoniae,* or *Staphylococcus aureus*) leading to acute and chronic pharyngitis, sinusitis, otitis media, bronchitis, and pneumonia.
  - Viruses that are cleared by neutralizing antibodies, e.g. enteroviruses
  - Parasites which are usually resisted by secretory IgA-e.g. *Giardia lamblia.*
- Autoimmune diseases (such as SLE and dermatomyositis) also occur in up to 20% of cases.

Common Variable Immunodeficiency

This is a heterogeneous group of both sporadic and inherited forms of the disease characterized by hypogammaglobulinemia, increased susceptibility to infection, autoimmune disorders (hemolytic anemia, pernicious anemia), as well as lymphoid tumors. The clinical manifestations are superficially similar to those of Bruton diseases; but differ in the following aspects:

- Both sexes are affected equally
- Onset of symptoms is much later, in the second or third decade of life.
- It is also B cell development defect; B cells may be present in circulation in normal numbers, but they appear defective in their ability to differentiate into plasma cells and secrete immunoglobulins.
- The diagnosis is usually one of exclusion (after other causes of immunodeficiency are ruled out); the basis of the immunoglobulin deficiency is variable (hence the name).

- The defect in the antibody production has been variably attributed to intrinsic B-cell defects, deficient T-cell help, or excessive T-cell suppressor activity.

Isolated IgA Deficiency

IgA deficiency is the most common of all the primary immunodeficiency diseases, affects about 1 in 700 white individuals.

- In healthy normal individuals, IgA is predominant in mucosal secretions and involves in providing immunity at mucosal sites of intestine and respiratory tract.
- Therefore, the weakened mucosal defences due to IgA deficiency predispose patients to recurrent sinopulmonary infections and diarrhea. There is also a significant (but unexplained) association with autoimmune diseases.
- **Pathogenesis:** IgA deficiency occurs due to a block in the terminal differentiation of IgA-secreting B cells to plasma cells, which in turn is due to altered T-cell production of cytokines that drive IgA responses (e.g. TGF-β and IL-5) or due to intrinsic B-cell defect. The levels of other immunoglobulins are usually normal or even excess.

Hyper-IgM Syndrome

Hyper-IgM syndrome is an X-linked disorder; results due to a defect in **isotype class switchover** of B cells.

- Class switchover is a phenomenon by which the same B cell, instead of producing IgM, starts producing other classes of antibodies. Class switch over depends upon two signals generated by helper T cells which influence the B cells—
  - T_H cell induced cytokine
  - Signal generated due to direct contact through the interaction of CD40 molecules on B cells with CD40 ligand (CD40L) on T_H cells
- **Genetic defect:** In hyper-IgM syndrome, there occur mutations in either CD40L or CD40 genes; prevent the T- and B-cell interaction; thus blocking the class switchover.
- A block in class switchover results in lack of synthesis of other classes of antibodies such as IgG, IgA, and IgE with a normal or supernormal levels of IgM.
  - Deficiency of IgG leads to defect in opsonization and complement activation (predisposes to recurrent pyogenic infections) and IgA deficiency leads to increased recurrent sinopulmonary infections and diarrhea.
  - Excess IgM antibodies can react with blood cells, resulting in autoimmune hemolytic anemia, thrombocytopenia, or neutropenia.
- Because CD40L signals are involved in macrophage activation and thus producing delayed hypersensitivity response, hence patients with defect in CD40L are more susceptible to *Pneumocystis jirovecii* infection.
- Hyper-IgM syndrome is X-linked in 70% of the cases affecting males; in the remaining patients, the precise mutations have not been fully characterized.

Transient Hypogammaglobulinemia of Infancy

This occurs due to an abnormal delay in the initiation of synthesis IgG (or some time IgA or IgM).

- IgG synthesis usually starts by 2 months of age. But in some infants, it is delayed leading to defect in opsonization or complement activation resulting in recurrent otitis media and respiratory infections.
- However, spontaneous recovery occurs usually by 18-24 months of age.
- Interestingly, these infants show a normal antibody response against vaccines.

CELLULAR IMMUNODEFICIENCIES (T CELL DEFECTS)

DiGeorge Syndrome (Thymic Aplasia)

DiGeorge syndrome results from a congenital defect in thymic development leading to defect in T-cell maturation.

- Infants are extremely vulnerable to viral, fungal, intracellular bacterial and protozoan infections.
- **Genetic defect:** In 90% of cases, there occurs a deletion affecting chromosome 22q11 which leads to developmental malformation affecting the third and fourth pharyngeal pouches in embryonic life.
- As a result, all the structures that develop from third and fourth pharyngeal pouches such as thymus, parathyroid glands, and portions of the face and aortic arch become defective.
- Thus, in addition to the thymic defects, there may be associated:
  - Parathyroid gland hypoplasia resulting in neonatal tetany and hypocalcemia.
  - Anomalies of the heart and the great vessels (Fallot's tetralogy).
  - Characteristic facial appearance.
- B cells and serum immunoglobulin levels are generally unaffected.
- Treatment: Thymus transplantation has been found to be successful in restoration of immune function. In others (with partial defects), immunity may improve spontaneously with age.

Chronic Mucocutaneous Candidiasis

It represents an impaired cell-mediated immunity against *Candida albicans* leads to superficial infections of the skin, mucous membranes, and nails.

- They do not show increased susceptibility to other infections but often associated with endocrinopathies and autoimmune disorders.
- Transfer factor therapy, along with amphotericin B has been reported to be effective.

Purine Nucleoside Phosphorylase Deficiency

It is a rare autosomal recessive disorder (chromosome 14), characterized by deficiency of an enzyme of purine metabolism called purine nucleoside phosphorylase (PNP).

- PNP is a key enzyme required for purine degradation; catalyzes the conversion of guanosine to hypoxanthine.
- Its deficiency leads to elevated deoxy-GTP levels resulting in T-cell toxicity. However, B cells are not affected.
- T cell depletion predisposes to increased susceptibility to infection and autoimmune disorders.

COMBINED IMMUNODEFICIENCIES (B AND T CELL DEFECTS)

Severe Combined Immunodeficiencies (SCID)

SCID represents groups of genetically distinct syndromes; all having in common, defects in both humoral and cell-mediated immune responses.

Types of Genetic Defect in SCID

- **Mutation in cytokine receptor:** Approximately 50-60% of the cases of SCID are X-linked (seen in males), resulting from mutations in the gene encoding the common γ chain shared by the cytokine receptors for IL-7 and others (IL-2, IL-4, IL-9, and IL-15).
  - IL-7 being lymphopoietic growth factor, defective IL-7 receptor signalling leads to defect in survival and expansion of immature B- and T-cell precursors in the bone marrow.
  - Defect in IL-15 receptor signalling leads to deficiency of NK cell.
- **The remaining cases of SCID** are inherited as autosomal recessive manner include:
  - **Adenosine deaminase (ADA) deficiency:** It is the most common type autosomal recessive SCID. ADA is an enzyme required for purine degradation; its deficiency leads to accumulation of deoxyadenosine which is toxic to rapidly dividing immature T lymphocytes. B cell deficiency is not profound.
  - **RAG Mutation:** Recombinase-activating genes (RAG) are essential for somatic gene rearrangements of T cell receptor and immunoglobulins. Thus, defect in RAG blocks the development of T and B cells.
  - **Jak3 mutation:** Jak3, an intracellular kinase, is essential for signal transduction through the common cytokine receptor γ chain. Hence Jak3 mutation is another way of blocking the cytokine receptor signalling.
  - **Class II MHC deficiency:** Mutations that impair the expression of class II MHC molecules prevent the development of CD4+ T cells. This condition is also called the **bare lymphocyte syndrome**.

Infections

Irrespective of the underlying genetic defect, the affected infants are susceptible to severe recurrent infections by a wide array of pathogens, including *Candida, Pneumocystis*, cytomegalovirus and *Pseudomonas* (Table 18.2).

Treatment

Bone marrow transplantation is the mainstay of treatment. Gene therapy replacing the mutated genes has been successful in X-linked cases.

Wiskott–Aldrich Syndrome (WAS)

It is an X-linked recessive disease, characterized by immunodeficiency with thrombocytopenia, eczema, etc. The severity of WAS increases with age.

- It first manifests itself by defective responses to bacterial polysaccharides and by lower IgM levels. IgG levels are usually normal. Paradoxically the levels of IgA and IgE are often elevated.
- Other T and B cell responses are normal initially, but with increase of age, there are recurrent bacterial infections and a gradual loss of humoral and cellular responses.
- Patients are also prone to develop non-Hodgkin B-cell lymphomas.
- Patients may present with bloody diarrhea secondary to thrombocytopenia.

Pathogenesis

The underlying genetic defect is due to a mutation in the gene encoding Wiskott–Aldrich syndrome protein (WASP) present in precursor lymphoid cells of bone marrow. It is a cytoskeletal glycoprotein (sialophorin or CD43), required for actin polymerization.

Ataxia Telangiectasia

The syndrome is characterized by:

- Difficulty in maintaining balance while walking (cerebellar ataxia).
- Appearance of broken capillaries (telangiectasia) in the eyes and choreoathetoid movements (usually noticed in infancy).
- Deficiency of IgA and sometimes IgE.
- Profound sinopulmonary infections.

Genetic defect: The primary defect appears to be in a kinase involved in regulation of the cell cycle. The relationship between the immune deficiency and the other defects in ataxia telangiectasia remains obscure.

Nezelof Syndrome

It is an autosomal recessive condition characterized by cellular immunodeficiency resulting from thymus hypoplasia.

- In some patients, B cells are normal, whereas in others a B-cell deficiency may be present, secondary to the T-cell defect.
- Affected individuals suffer from chronic diarrhea, viral and fungal infections, and a general failure to thrive.

DISORDERS OF PHAGOCYTOSIS

Chronic Granulomatous Disease (CGD)

Pathogenesis

Pathogenesis of CGD involves inherited defects in the gene encoding components of oxidase system, e.g. Nicotinamide adenine dinucleotide phosphate (NADP) oxidase of phagocyte which breaks down hydrogen peroxide to generate free oxygen radicals (O_2^-) that are involved in microbial killing. As a result, there occurs decreased oxidative burst which predisposes to recurrent bacterial infections. CGD is a genetic disease that runs in family in two forms:

- In X-linked form (more common, 70%), membrane component of phagocyte oxidase is defective.
- In autosomal recessive form, cytoplasmic component of phagocyte oxidase is defective.

Manifestations

- The bacteria involved in the recurrent infections are catalase positive; pyogenic pathogens such as staphylococci, *Pseudomonas* and coliforms. Catalase negative pathogens such as streptococci and pneumococci are handled well.
- Patients also undergo excessive inflammatory reactions that result in gingivitis, swollen lymph nodes, and nonmalignant granulomas (lumpy subcutaneous cell masses).
- Nitroblue tetrazolium reduction test (NBT) is used as screening test to detect deficiency of NADPH oxidase activity.

Myeloperoxidase Deficiency

It is a common genetic disorder characterized by deficiency in either quantity or function, of myeloperoxidase, an enzyme produced by neutrophils. Patients present with immune deficiency and recurrent infections, especially with *Candida albicans*.

Chediak–Higashi Syndrome

It is an autosomal recessive disease, characterized by:

- Defective fusion of phagosomes and lysosomes in phagocytes which leads to increased susceptibility to recurrent and severe pyogenic infections.
- Abnormalities in melanocytes leading to albinism (lack of skin and eye pigment)
- Abnormalities in cells of the nervous system (associated with nerve defects), and
- Platelets abnormalities, causing bleeding disorders.
- Aggressive but non-malignant infiltration of organs by lymphoid cells.

Genetic defect: Pathogenesis of this syndrome is due to a mutation in a protein called LYST which is believed to regulate lysosomal trafficking.

- The mutation impairs the targeting of proteins to secretory lysosomes, which makes them unable to lyse bacteria.
- Phagocytes from patients with this immune defect contain *giant granules* but do not have the ability to kill bacteria.

Leukocyte Adhesion Deficiency (LAD)

LAD is rare autosomal recessive disorder, characterized by a defect in the adhesion of leukocytes which results in poor leukocyte chemotaxis particularly neutrophil, inability to form pus. Thus it predisposes to various bacterial and fungal infections. LAD is of two types:

- **Leukocyte adhesion deficiency 1:** Defective leukocyte adhesion because of mutations in β2 integrin subunit (CD18), of the leukocyte cell adhesion molecule, which is found on chromosome 21.
- **Leukocyte adhesion deficiency 2:** Defective leukocyte adhesion is because of mutations in fucosyltransferase required for synthesis of sialylated oligosaccharide which is a selectin ligand.

Lazy Leukocyte Syndrome

It is an idiopathic condition due to defect in neutrophil chemotaxis which results in increased pyogenic infections such as gingivitis, abscess formation, pneumonia and neutropenia.

Job's Syndrome (Hyper-IgE Syndrome)

Hyper-IgE syndrome is a rare primary immunodeficiency disease characterized by eczema, recurrent staphylococcal skin abscesses, recurrent lung infections (pneumatocele), eosinophilia and high serum levels of IgE.

Genetic defect: The underlying mechanism is due to a defect in neutrophil chemotaxis. Most cases are sporadic, but some familial cases of Hyper-IgE syndrome have been reported, with either an autosomal dominant (AD) or autosomal recessive (AR) mode of inheritance.

- Autosomal dominant cases are linked to mutations in the STAT3 gene.
- Autosomal recessive cases are due to mutations in DOCK8 gene.

Tuftsin Deficiency

Tuftsin is a tetrapeptide (Thr-Lys-Pro-Arg) produced primarily in the spleen, by the cleavage of the Fc-portion of the heavy chain of IgG. It stimulates the bactericidal activity of phagocytes. Tuftsin deficiency, either hereditary or following splenectomy, results in increased susceptibility to certain capsulated organisms such as *H. influenzae*, pneumococci, and meningococci.

Shwachman's Syndrome

It is a rare congenital disorder characterized by neutropenia, exocrine pancreatic insufficiency, bone marrow dysfunction, skeletal abnormalities, and short stature.

SECONDARY IMMUNODEFICIENCIES

Secondary immunodeficiencies, also known as acquired immunodeficiencies, are due to the secondary effects of other diseases, such as:

- Malnutrition (due to inadequate immunoglobulin synthesis)
- Aging (suppression of immune system with age)
- Patients with several infections that supress immune system causing lymphocyte depletion, e.g. HIV (human immunodeficiency virus) infection
- Underlying cancers (particularly those of the bone marrow and blood cells (leukemia, lymphoma, multiple myeloma)
- Underlying proteinuric renal diseases—leads to loss of immunoglobulins
- Sarcoidosis
- Patients on immunosuppressive medications
- Patients receiving chemotherapy or radiation therapy for malignancy

As a group, the secondary immunodeficiencies are more common than the primary immunodeficiency disorders. Acquired immunodeficiency syndrome (AIDS), the most widespread and important of the secondary immunodeficiency diseases, is discussed in detail in Chapter 48.

EXPECTED QUESTIONS

I. Essay:

1. Define and classify immunodeficiency diseases. Describe in detail about Bruton's disease.

II. Write short notes on:

1. Severe combined immunodeficiencies
2. DiGeorge syndrome
3. Chediak–Higashi syndrome
4. Chronic granulomatous disease
5. Wiskott–Aldrich syndrome

III. Multiple Choice Questions (MCQs):

1. DiGeorge syndrome is due to:
   a. T cell defect
   b. B cell defect
   c. Phagocyte defect
   d. Complement defect

2. All of the following are primary immunodeficiency diseases except:
   a. DiGeorge syndrome
   b. Nezelof syndrome
   c. Chediak–Higashi syndrome
   d. AIDS

3. Chronic granulomatous disease is due to deficiency of:
   a. Tyrosine kinase
   b. NADPH oxidase
   c. Adenosine deaminase
   d. Myeloperoxidase

Answers

1. a **2.** d **3.** b

CHAPTER 19

Transplant and Cancer Immunology

Chapter Preview

- Transplant Immunology
  - Classification of transplants
  - Histocompatibility antigens
  - Types of graft rejection
  - Mechanism of graft rejection
  - Prevention of graft rejection
  - Graft–versus–host reaction
- Cancer immunology
  - Tumor antigens
  - Immune surveillance theory
  - Cancer immunotherapy

Organ transplantation and cancer are two situations in which the host immune system plays a deciding role in the survival of such transplants or tumors inside the host.

- In organ transplantation, immune response against the graft is a barrier to successful transplantation, and suppression of the immune system is the key for the transplant survival.
- In cancer, the situation is precisely the reverse: suppressed immune system gives opportunity for many tumors to take birth and enhancing the immunity against the tumor cells, is the principle used for treatment of cancers.

TRANSPLANT IMMUNOLOGY

Transplantation refers to transfer of a graft or transplant (cells, tissues, or organs) from one site to another. The individual from whom the transplant is taken is referred to as the **donor**; while the individual to whom it is transplanted, is called **recipient**.

CLASSIFICATION OF TRANSPLANTS

Transplants are classified in various ways.

- **Based on the organ or tissue transplanted:** Examples are kidney, heart and skin grafts, etc.
- **Based on the anatomical site of the graft**
  - Orthotopic grafts: When the tissue or organ grafts are transplanted to their anatomically 'normal' sites in the recipient, then such grafts are known as orthotopic grafts, e.g. as in skin grafts.
  - Heterotopic grafts: They are placed in anatomically 'abnormal' sites, as when thyroid tissue is transplanted in a subcutaneous pocket.
- **Vital and static transplants**:
  - Vital grafts are the live grafts, such as the kidney or heart, are expected to survive and function physiologically in the recipient.
  - Static grafts are nonliving structures, like bone or artery which merely provide a scaffolding on which new tissue is laid by the recipient.
- **Based on the genetic relationship** between the donor and the recipient:
  - Autograft: It is a self-tissue transferred from one part of the body site to another in the same individual. Examples include transferring healthy skin to a burned area in burn patients and use of healthy blood vessels of the same person to replace blocked coronary arteries.
  - Isograft or syngeneic graft: It is a tissue transferred between genetically identical individuals (e.g. monozygotic twins)
  - Allograft: It is a tissue transferred between genetically non-identical members of the same species (e.g. kidney or heart transplant).
  - Xenograft: It is a tissue transferred between different species (e.g. the graft of a baboon heart into a man).

In humans, allografts are the most commonly used graft in transplant centres; hence our further discussion will be confined to allografts.

HISTOCOMPATIBILITY ANTIGENS

Histocompatibility

Histocompatibility between the graft and recipient would decide whether the graft is going to be accepted or rejected.

- If a graft and recipient tissues are histocompatible to each other (i.e. antigenically similar); then the

graft is accepted. Usually, autografts and isografts are histocompatible.

- On the contrary, histoincompatible (i.e. antigenically dissimilar) grafts are generally rejected by the recipient. Allografts and xenografts are usually histoincompatible.

Transplantation Antigens

Transplantation antigens are the antigens of allografts against which the recipient would mount an immune response.

- MHC molecules (major histocompatibility antigens) are the most important transplantation antigens.
- Apart from that, ABO and Rh blood group systems also play a role in determining the histocompatibility.
- **Minor histocompatibility antigens (MHA):** They are the peptides derived from normal cellular proteins of donated organs. Immune response against MHA molecules is weaker; hence they pose problems of rejection less frequently than MHC molecules. One exception is when a graft is transferred from a male donor to a female recipient.
  - The graft tissues of a male donor (XY) would have some male-specific minor histocompatibility (H-Y) antigens determined by the Y chromosome which will be absent in the female (XX) recipient.
  - Hence, it is observed that the rejection of the grafts when transferred from a male donor to female recepient is more as compared to female to male transplantation.
  - This unilateral sex linked histoincompatibility is known as the **Eichwald–Silmser effect**.

TYPES OF GRAFT REJECTION

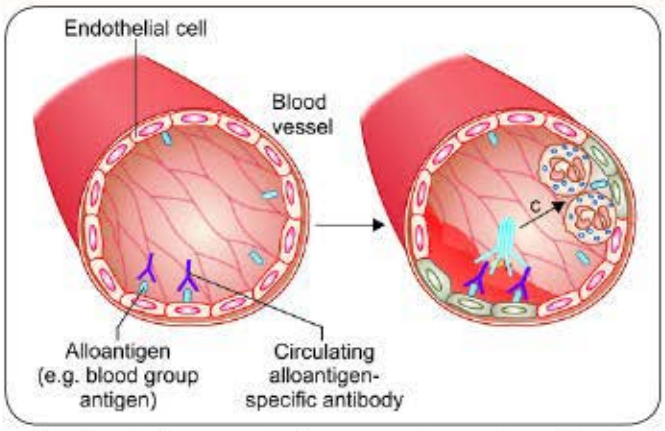
Graft rejection is classified into hyperacute, acute, and chronic, on the basis of time taken for the rejection, types of immune response mounted against the graft and clinical & pathologic features (Table 19.1).

Hyperacute Rejection

This occurs within minutes to hours of transplantation and is characterized by thrombosis of graft vessels and ischemic necrosis of the graft.

TABLE 19.1: Comparison of various types of graft rejection

Graft rejection	Time taken for rejection	Immune mechanisms involved
Hyperacute	Minutes to hours	Preformed antibodies (anti-ABO and/or anti-HLA)
Acute	Weeks to months	▪ Cytotoxic T cell mediated ▪ Antibody mediated
Chronic	Months to years	▪ Chronic DTH mediated ▪ Antibody mediated



Preformed antibodies react with alloantigens on the vascular endothelium of the graft, activate complement (C) and trigger rapid intravascular thrombosis and necrosis of the vessel wall.

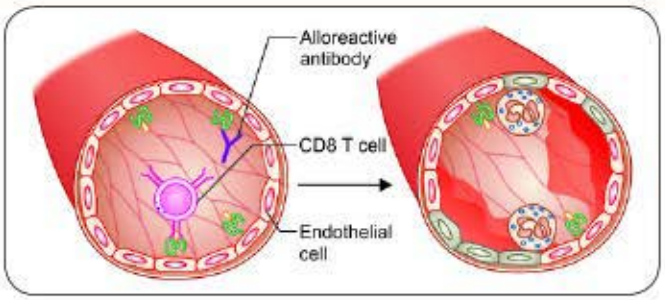
Fig. 19.1: Hyperacute graft rejection

- It is mediated by **circulating antibodies** that are specific for antigens on the graft endothelial cells and that are present before transplantation.
- In an individual, exposure to foreign HLA antigens can occur as a consequence of previous blood transfusions, pregnancy, or organ transplantation. Following which, the individual develops antibodies against these antigens. These preformed antibodies may be anti-ABO or anti-HLA specific for allogenic (i.e. graft's) MHC molecules. If an individual with these pre-existing antibodies to a foreign HLA antigen receives a graft (containing same foreign HLA antigen), then the graft will be rejected earlier and more vigorously (Fig. 19.1).
- Hyperacute rejection is not a common problem in clinical transplantation, because it can be avoided by matching the donor and the recipient. Potential recipients are tested for antibodies against the prospective donor's blood group antigens (by cross matching) and HLA antigens (by HLA typing).

Acute Graft Rejection

Acute graft rejection occurs within days or weeks after transplantation. It is due to an active immune response of the host stimulated by alloantigens in the graft.

- Acute graft rejection is mediated by T cells (mainly cytotoxic T cells, occasionally helper T cells) and antibodies specific for alloantigens in the graft.
- Cytotoxic T cells directly destroy the graft cells, or cytokines secreted by the helper T cells induce inflammation, which destroys the graft.
- Antibodies contribute especially to the vascular component of acute rejection. Antibody-mediated injury to graft vessels is caused mainly by complement activation by the classical pathway (Fig. 19.2).



CD8 T cells react with graft alloantigens and destroy the endothelial and parenchymal cells or antibodies react with alloantigens of the graft's endothelium and causes endothelial cell damage via complement activation.

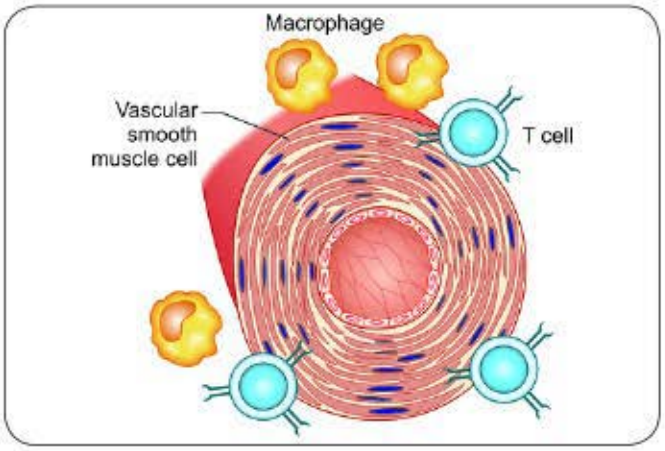
Fig. 19.2: Acute graft rejection

- Current immunosuppressive therapy is designed mainly to prevent and reduce acute rejection by blocking the activation of alloreactive T cells.

Chronic Graft Rejection

Chronic graft rejection is an indolent form of graft damage that occurs over months or years, leading to progressive loss of graft function.

- Chronic rejection may be manifested as fibrosis of the graft and by gradual narrowing of graft blood vessels, called graft arteriosclerosis.
- T cells that react against graft alloantigens secrete cytokines, which stimulate the proliferation and activities of fibroblasts and vascular smooth muscle cells in the graft. The smooth cell proliferation in the vascular intima may represent a specialized form of chronic delayed type hypersensitivity (DTH) reaction (Fig. 19.3).



T cells react with graft alloantigens may produce cytokines that induce inflammation and proliferation of intimal smooth muscle cells, leading to luminal occlusion and graft arteriosclerosis

Fig. 19.3: Chronic graft rejection

- Alloantibodies also contribute to chronic rejection.
- Chronic rejection is refractory to most of the therapeutic options available and is becoming the leading cause of graft failure.

FACTORS INFLUENCING ALLOGRAFT REJECTION

The rate of allograft rejection varies according to the—

- **Tissue involved**, e.g. skin grafts are rejected faster than other tissues such as kidney or heart.
- **Genetic distance** between the donor and recipient- More the genetic distance; faster is the rejection. Autografts and isografts are well accepted.
- **Immunological memory:** Rejection is faster when another graft is placed to a recipient from the same donor. This occurs due to the memory cells produced against the first graft would differentiate into effector cells; and that in turn reject the second graft faster.

An example is given below which describes the pathological sequences that take place when a skin graft is placed: (1) as an autograft to the same donor (leads to acceptance), (2) as an allograft to a recipient for the first time(leads to first set rejection), (3) as an allograft to the same recipient for the second time (leads to second set rejection).

Autograft Acceptance

When a skin graft is transplanted to the same individual at a different site, revascularization takes place by day 3–7; followed by healing (within day 7–10) and then resolution and acceptance of the graft (by day 12–14) (Fig. 19.4A).

First-set Rejection

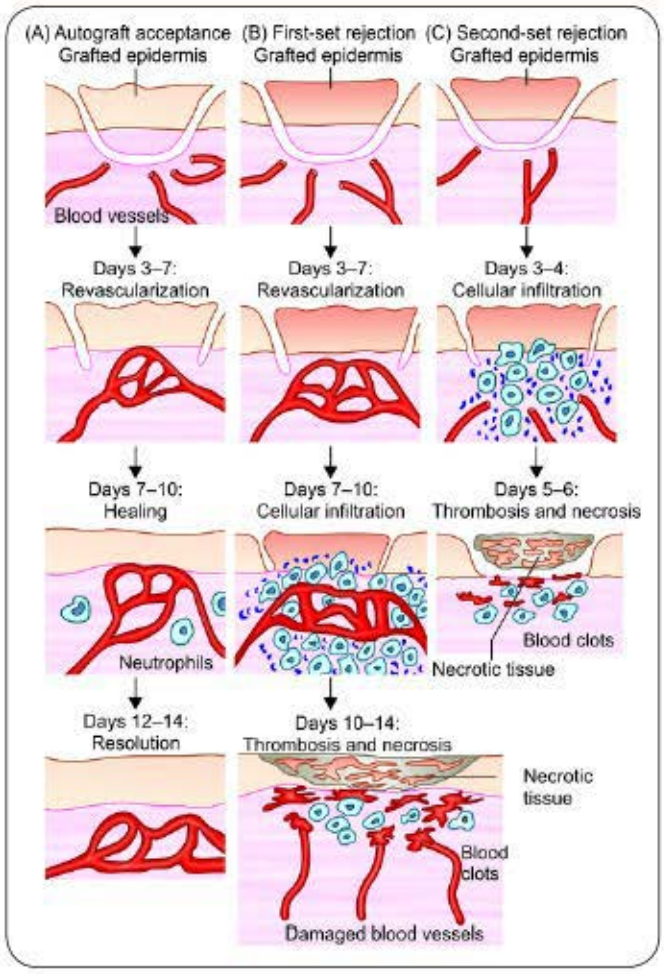
When an allograft is placed for the first time from a donor to a recipient, the type of primary graft rejection that develops is known as, **first-set rejection** (Fig. 19.4B).

- The skin first becomes revascularized between days 3 and 7; as the reaction develops, the vascularized transplant becomes infiltrated with lymphocytes, monocytes, neutrophils, and other inflammatory cells.
- There is decreased vascularization of the transplanted tissue by 7–10 days, visible necrosis by 10 days, and complete rejection by 12–14 days.

Second-set Rejection

If, in a recipient that has rejected a graft by the first set response, another graft from the same donor is transplanted, it will be rejected in an accelerated fashion.

- Though vascularisation starts but is soon interrupted by the inflammatory response.
- Necrosis sets in early and the graft sloughs off by the sixth day (Fig. 19.4C).



Figs 19.4A to C: Graft acceptance and graft rejection

MECHANISM OF GRAFT REJECTION

Graft rejection is caused principally by a T cell-mediated immune response to alloantigens expressed on the graft cells, primarily the MHC molecules (Fig. 19.5).

The T cell response to MHC antigens involves recognition of both the donor MHC molecule as well as the associated peptide ligand present in the cleft of the MHC molecule.

- The peptides present in the groove of allogeneic (i.e donor) class I MHC molecules are derived from proteins synthesized within the allogeneic cell.
- The peptides present in the groove of allogeneic (i.e. donor) class II MHC molecules are generally proteins taken up and processed by the allogeneic APCs.

The process of graft rejection can be divided into two stages: (1) A sensitization phase-which involves alloantigen (mainly graft MHC molecules) presentation to recipient's T cells and (2) An effector stage, in which immune destruction of the graft takes place due to activation of recipient's T cells.

Sensitization Phase

T cells in the recipient may recognize donor alloantigens in the graft in two different ways: (1) direct pathway and (2) indirect pathway; depending on what cells in the graft are displaying these alloantigens to the recipient T cells (Fig. 19.5).

Direct Pathway of Alloantigen Presentation

Many graft tissues contain antigen presenting cells (APCs, e.g. dendritic cells) and when the tissues are transplanted, the APCs are also carried along with the graft to the recipients.

- The allogeneic MHC molecules on graft's APCs are directly presented to the recipient's helper T cells.
- This pathway is responsible for most of the acute graft rejections mediated by cytotoxic T cells (described in effector phase).

Indirect Pathway of Alloantigen Presentation

This is similar to that for recognition of any foreign antigen by the host APCs.

- The graft cells are ingested by recipient APCs, donor alloantigens are processed and presented by the MHC molecules present on recipient APCs to recipient's helper T cells.
- This pathway is responsible for most of the chronic rejection mediated by helper T cells via specialized form of chronic DTH reaction (described in effector phase).

Effector Phase

A variety of effector mechanisms participate in allograft rejection. The most common are cell-mediated reactions involving delayed-type hypersensitivity T cells and cytotoxic T cells.

- **Delayed-type hypersensitivity:** Activated helper T cells differentiate into T_{DTH} cells. Cytokines secreted from T_{DTH} (e.g. interferon-γ) activate macrophages which destroy the target graft cells by producing lytic enzymes.
- **Cytotoxic T cells:** $CD8^+$ T_C cells kill the graft cells by recognizing the allogeneic MHC-I molecules.
- **Antibody-mediated mechanisms:** Cytokines produced by helper T cells activate B cells to produce antibodies. Antibodies are also important in mounting immune response against the graft. They take a lead role in mediating hyperacute graft rejections; however, in acute and chronic rejections, they play a minor role. Antibody-mediated destruction of the graft occurs by the following mechanisms:
  - Complement-mediated lysis
  - Antibody-dependent cell-mediated cytotoxicity (ADCC) via NK cell or macrophage mediated destruction.

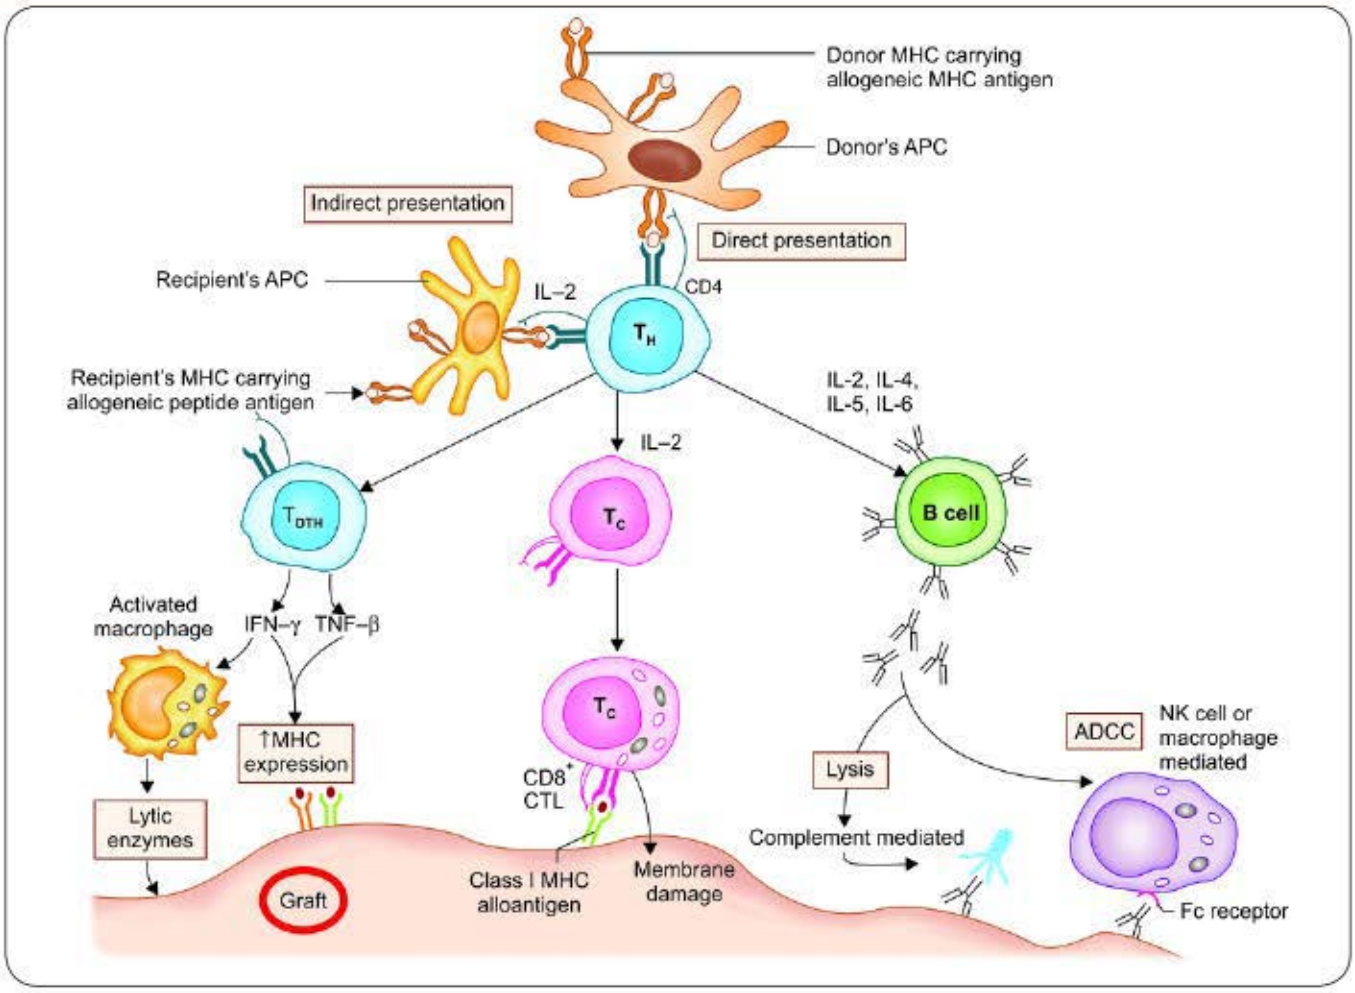


Fig. 19.5: Mechanisms involved in graft rejection

Abbreviations: MHC, major histocompatibility complex; NK, natural killer; APC, antigen presenting cells; IL, interleukin; TNF, tumor necrosis factor; IFN, interferons; CTL, cytotoxic-T lymphocytes

PREVENTION OF GRAFT REJECTION

Laboratory Tests to Determine Histocompatibility

Prior to transplantation, various laboratory tests should be carried out to assess the histocompatibility between the donor and recipient.

- ABO blood group compatibility testing by blood grouping and cross matching.
- HLA typing (see highlight box).

Immunosuppressive Therapy

- Hyperacute rejection manifests severely and within minutes, and so the treatment indicated is immediate removal of the tissue.

HLA Typing

In this test, donor's antigens expressed on the surface of leukocytes or their gene to that of recipient are matched. The HLA compatibility is determined by

- **Phenotypic method**, such as
  - Serology: Microcytotoxicity
  - Tissue typing: Mixed lymphocyte reaction
- **Genotypic methods**, such as
  - PCR detecting HLA genes
  - PCR-RFLP (restriction fragment length polymorphism)
  - Variable number tandem repeat (or VNTR) typing
  - STR (Short tandem repeat) typing
  - DNA Sequence based typing
  - Karyosome analysis

The phenotyic methods were used widely in the past. But with the advent of molecular methods, they are not preferred now. VNTR typing and DNA sequecing are one of the most reliable method for HLA typing.

TABLE 19.2: Immunosuppressive agents used to improve graft survival

Immunosuppressive drugs:	
Corticosteroids	Prednisolone, hydrocortisone
Calcineurin inhibitors	Cyclosporine, Tacrolimus
Mitotic inhibitors	Azathioprine Cyclophosphamide Methotrexate
Antiproliferatives	Mycophenolic acid
mTOR inhibitor(mammalian target of rapamycin)	Sirolimus (rapamycin) Everolimus
Monoclonal antibody based	
mAb to CD2 molecule present on T cell surface	OKT2
mAb to CD3 molecule present on T cell surface	OKT3
mAb to CD4 molecule present on T cell surface	OKT4
Monoclonal anti-IL-2Rα receptor antibodies	Basiliximab Daclizumab
Monoclonal anti-CD20 antibodies	Rituximab
mAb to TNFα	Infliximab
Antithymocyte globulin (ATG)	
Antilymphocyte globulin (ALG)	

- Chronic rejection is generally considered irreversible and poorly amenable to treatment—only retransplant generally indicated if feasible—though inhaled cyclosporine is being investigated to delay or prevent chronic rejection of lung transplants.
- Acute rejection is treated with therapeutic regimens consisting of one or combination of various immunosuppressive therapies as given in Table 19.2.

Graft–Versus–Host Reaction

Graft–versus–host (GVH) reaction is a condition, where graft mounts an immune response against the host (i.e. recipient) and rejects the host, in contrary to the ususal situation of graft rejections, in which the recepient mounts an immune response against the graft antigens.

The GVH reaction occurs when the following three conditions are present:

1. The graft must contain immunocompetent T cells (e.g. stem cells or bone marrow or thymus transplants)
2. The recipient should possess transplantation antigens that are absent in the graft.
3. The recipient may be immunologically suppressed and therefore cannot mount immune respponse against the graft.

Contd...

Contd...

Types

GVH disease occurs in two forms:

1. Acute or fulminant GVH disease occurs within first 100 days of post-transplantation. It is a major challenge in case of bone marrow transplantation.
2. Chronic GVH disease is less severe form, occurs after 100 days of transplantation.

Clinical Manifestations

- The acute GVH disease is characterized by selective damage to the liver (hepatomegaly), skin (rash), mucosa, and the intestine (diarrhea) mediated graft's immunocompetent T cell. Experimentally, GVH can be produced in mice, called **Runt disease**.
- Chronic GVH disease also attacks the above organs, but in addition, it causes damage to the connective tissues and exocrine glands.

Treatment

Glucocorticoids (administrated intravenously) are the standard treatment given for both acute and chronic GVH disease.

CANCER IMMUNOLOGY

Tumor immunology involves the study of antigens on tumor cells and the immune response to these antigens.

TUMOR ANTIGENS

Two types of tumor antigens have been identified on tumor cells:

1. Tumor-specific transplantation antigens (TSTAs)
2. Tumor-associated transplantation antigens (TATAs)

Tumor-specific Transplantation Antigen

Tumor-specific antigens are present only on tumor cells and are absent in normal cells of the body.

They may result from mutations in tumor cells that generate altered cellular proteins; cytosolic processing of these proteins would give rise to novel peptides that are presented with class I MHC molecules, inducing a cell-mediated immune response by tumor-specific cytotoxic T lymphocytes.

TSTAs are induced on tumor cells either by chemical or by physical carcinogens, and also by viral carcinogens.

- In chemically/physically induced tumors, the TSTA is tumor specific. Different tumors possess different TSTA, even though induced by the same carcinogen. Methylcholanthrene and ultraviolet light are the examples of chemical and physical carcinogens that are extensively studied.
- In contrast, the TSTA of virus induced tumors is virus specific; all tumors produced by one virus would

TABLE 19.3: TATAs used as tumor markers for diagnosis of cancers

Tumor markers	Tumor types
Oncofetal proteins	
Alpha-fetoprotein (AFP)	Hepatoma Testicular cancer
Carcinoembryonic antigen (CEA)	Gastrointestinal cancers Lung, ovarian cancers
Secreted tumor antigens	
CA 125	Ovarian cancers Other epithelial cancers
CA 19-9	Various carcinomas
Prostate-specific antigen	Prostate cancer
β2 microglobulin	Multiple myeloma
Hormones	
β subunit of chorionic gonadotropin	Hydatidiform mole Choriocarcinoma Testicular cancers

possess the same antigen. Example include Epstein–Barr virus which causes nasopharyngeal carcinoma and several types of lymphoma.

Tumor-associated Transplantation Antigens

Tumor-associated antigens (TATAs) are not unique to tumor cells and may also be expressed by normal cells, but at a very low level. Their level gets exponentially high in tumor cells. Examples include (Table 19.3):

- **Oncofetal antigens:** They are the proteins that are expressed on normal cells during fetal life, but not expressed in the adult normally.
  - Reactivation of the embryonic genes that encode these proteins in tumor cells results in their expression on the fully differentiated tumor cells.
  - Examples include alpha-fetoprotein (AFP) and carcinoembryonic antigen (CEA).
- **Non-oncofetal TATAs:** Examples include carbohydrate antigens (CA 125, CA 19-9), prostate specific antigen and macroglobulin.

IMMUNE RESPONSE AGAINST TUMOR CELLS

Both humoral and cell-mediated immune responses are induced by tumor antigens that result in the destruction of the tumor cells. In general, the cell-mediated response appears to play the major role, especially cytotoxic T cell and NK cell.

Cytotoxic T Cells

A number of tumors have been shown to induce tumor-specific T_C cells that recognize tumor antigens presented by class I MHC on the tumor cells. However, as the expression of class I MHC molecules are decreased in a number of tumors, thereby limiting the role of specific T_C cells in their destruction.

Natural Killer (NK) Cells

The recognition of tumor cells by NK cells is not MHC restricted. The activity of NK cells is not compromised; but enhanced by the decreased MHC expression exhibited by some tumor cells.

- This is due to withdrawal of inhibitory receptors induced NK cells suppression. The inhibitory receptors of NK cells will be no longer functional in the absence of MHC I molecules on the target cells so that the activation receptors become active.
- The activation receptors can be Fc receptors on NK cells which can bind to antibody-coated tumor cells, leading to ADCC.
- The importance of NK cells in tumor immunity is suggested by the mutant mouse strain called **beige** and **Chediak–Higashi syndrome** in humans. In each case, a genetic defect causes marked impairment of NK cells and an associated increase in certain types of cancer.

IMMUNE SURVEILLANCE THEORY

Theory of immunological surveillance (conceptualized by Paul Ehrlich) postulates that the tumor cells may arise frequently in our body but are recognized as foreign and are eliminated by the constant vigilance of our immune system.

Later, Lewis Thomas revived the theory by suggesting the role of cell-mediated branch of the immune system to patrol the body and eliminate cancer cells.

Immune evasion by tumor cells is described in detail in the box given below:

Immune Evasion by Tumor Cells

The immune surveillance hypothesis though looks attractive, it does not hold always true. In real situation, there are a number of immune evasion mechanisms by which tumor cells bypass the immune surveillance mechanisms.

- **Antitumor antibodies** produced against tumor antigens may have a role in immune evasion.
  - Blocking factor: Antitumor antibody may act as a blocking factor. The antibody binds to tumor-specific antigen and masks the antigen from cytotoxic T cells and NK cells.
  - Antigenic modulation: Certain tumor-specific antigens have been observed to disappear from the surface of tumor cells in the presence of serum antibodies and then to reappear after disappearance of serum antibodies.

Contd...

Contd...

- **Masking the immune cells:** Circulating tumor antigens may act as a 'smokescreen,' coating the lymphoid cells and preventing them from acting on the tumor cells.
- **Expressing low levels of MHC I:** Many tumor cells down regulate the expression of MHC I molecules; hence preventing their recognition by cytotoxic T cells.
- **Poor costimulatory signals:** The costimulatory signal of T cell activation is provided by interaction between the CD28 molecules on T cell surface with the B7 molecules on the APCs. The poor immunogenicity of many tumor cells may be due to lack of the costimulatory molecules on APCs.
- **Secrete soluble factors:** Certain tumor cells secrete soluble factors such as IL-10 and TGF-β that may suppress the immune responses against the tumor cells.
- **Expressing Fas ligand:** Some tumor cells express Fas ligand on their surface, which when interact with Fas (the death receptor) on T cells, causes apoptosis of T cells.
- **↑Opportunistic infections:** Patients with advanced cancers have an increased susceptibility to various opportunistic infections which in turn depresses the T cell responses.

CANCER IMMUNOTHERAPY

Cancer immunotherapy is the use of the immune system to treat cancer. There are three main groups of immunotherapy used to treat cancer: cell-based therapies, antibody therapies and cytokine therapies. They all provoke the immune system to attack the tumor cells by using these cancer antigens as targets.

Cell-based Therapies

Cell-based therapies, also known as **cancer vaccines,** usually involve the removal of immune cells from patients with cancer, either from the blood or from a tumor →immune cells specific for the tumor will be activated, grown and returned to the person with cancer →where the immune cells provoke an immune response against the cancer.

- Cell types that can be used in cancer vaccines include NK cells, cytotoxic T cells and dendritic cells.
- The only cell-based therapy currently approved for use is dendritic cells (Provenge) for the treatment of prostate cancer.

Monoclonal Antibodies

Monoclonal antibody (mAb) therapies are currently the most successful form of immunotherapy. Many mAbs are approved for treatments of a wide range of cancers (Table 19.4).

- They are usually targeted against the cell surface molecules, e.g. the epidermal growth factor receptor.

TABLE 19.4: Monoclonal antibodies approved for treatment of cancers

Monoclonal antibodies	Target	Approved for treatment of cancers
Alemtuzumab	CD52	Chronic lymphocytic leukemia (CLL)
Bevacizumab	Vascular endothelial growth factor	Colorectal, lung and renal cell cancer
Cetuximab	Epidermal growth factor receptor	Colorectal, the head and neck cancer
Ipilimumab	CTLA4	Metastatic melanoma
Rituximab	CD20	CLL
Tositumomab	CD20	Non-Hodgkin lymphoma
Trastuzumab	ErbB2	Breast cancer

- Once bound to the surface receptors on the tumor cells, antibodies can induce tumor cell death by several mechanisms such as ADCC, complement activation or by preventing the surface receptor to interact with its ligand.
- Conjugated mAb: When such mAb conjugated to a toxic molecule is used; the mAb binds to its receptor on tumor cells and delivers the toxic molecule to exert lethal effect on the tumor cells.
- The toxic molecule used to conjugate mAb may be either a toxin such as tetanus toxin or diphtheria toxin (immunotoxin) or chemical or radioactive substance.

Cytokine Therapies

Administration of cytokines can regulate and coordinate the behaviour of the immune system. Examples include:

- **Interferon α:** It is used in the treatment of hairy-cell leukaemia, AIDS-related Kaposi's sarcoma, follicular lymphoma, chronic myeloid leukaemia and malignant melanoma.
- **Interleukin-2:** It is used in the treatment of malignant melanoma and renal cell carcinoma.

Cancer Vaccine

They are used for treatment of existing cancers or prevention of emergence of new cancers.

- **Preventive cancer vaccines:** Examples of HPV vaccine and hepatitis B vaccine will prevent the emergence cervical and liver cancers, respectively.
- **Therapeutic cancer vaccines:** They are used to treat existing cancers. Research is ongoing for preparation of such vaccines. Vaccines against some oncogenic viruses have proven extremely effective.

EXPECTED QUESTIONS

I. Essay:

1. A 55-years-male patient with chronic kidney disease underwent a kidney transplantation donated by a donor. Patient developed rejection reaction within 3 weeks.
   a. What is the immunological process of rejection?
   b. Mention the pre-transplantation investigations to know the suitability of transplant?
   c. How can this be prevented?

II. Write short notes on:

1. Graft–versus–host reaction
2. Immune evasion by tumor cells
3. Immunotherapy for tumors

III. Multiple Choice Questions (MCQs):

1. Application of skin graft for the second time from the same donor will result in:
   a. First set rejection
   b. Second set rejection
   c. Both
   d. None

2. Transplantation between members with same genetic constitution is known as:
   a. Autograft
   b. Isograft
   c. Allograft
   d. Xenograft

3. Graft rejection due to preformed antibodies occurs in:
   a. Hyperacute rejection
   b. Acute rejection
   c. Subacute rejection
   d. Chronic rejection

4. All of the following are tumor associated transplant antigens except:
   a. Prostate-specific antigen
   b. Carcinoembryonic antigen
   c. CA 125
   d. Rituximab

Answers

CHAPTER 20

Immunoprophylaxis and Immunohematology

Chapter Preview

- Immunoprophylaxis
  - Active immunoprophylaxis
  - Passive immunoprophylaxis
- Immunohematology
  - Blood group system (ABO, Rh and others)
- Safe blood transfusion practices
- Transfusion reactions
- Transfusion transmitted infections

IMMUNOPROPHYLAXIS

Immunoprophylaxis against microbial pathogens can be classified into active immunoprophylaxis (or vaccination) and passive immunoprophylaxis (or immunoglobulin administration).

VACCINATION (ACTIVE IMMUNOPROPHYLAXIS)

Vaccine is an immunobiological preparation that provides specific protection against a given disease. Following vaccine administration, the immunogen (active ingredient of the vaccine) stimulates the immune system of the body to produce active immunity in the form of protective antibody and/or immunocompetent T cell response.

- **History:** The terms vaccine and vaccination are derived from '*Variolae vaccinae*' (smallpox of the cow), the term devised by Edward Jenner to denote cowpox. Later, to honor Jenner, Louis Pasteur proposed that these terms should be extended to cover all the new protective preparations being developed, in the memory of Edward Jenner.
- **Valency:** Vaccines may be **monovalent** that contains single antigen or single serotype of a microorganism) or **polyvalent** (contains two or more strains of the same microorganism), e.g. trivalent vaccines such as influenza vaccine and polio vaccine.
- **Homologous and heterologous vaccine:** In most vaccines, the immunizing substance is derived from the same microorganism against which it is used (homologous vaccine). However, there are few exceptions, where the vaccine organism is different from the disease-causing organism. Such vaccines are called as heterologous or "Jennerian" vaccines. Examples include—
  - The classic example is Jenner's use of cowpox to protect against smallpox.
  - Use of BCG vaccine made from *Mycobacterium bovis* to protect against human tuberculosis caused by *M. tuberculosis*.
- **Types:** Vaccine may be prepared by live modified organisms, inactivated or killed organisms, extracted or cellular fractions, toxoids or combinations of all these. Preparations that are more recent are subunit vaccines and recombinant vaccine. Vaccines of future prospects include DNA vaccine and edible vaccine.

Live Attenuated Vaccine

Live vaccines, such as BCG (Table 20.1) are prepared from live (usually attenuated) organisms.

- The live attenuated organisms lose the ability to induce full blown disease, but retain their immunogenicity.
- Attenuation is achieved by passing the live organisms serially through a foreign host, such as chick embryo/tissue culture or live animals.

  Note: Smallpox vaccine is a live vaccine which is not attenuated. The nonpathogenic cross reactive *Vaccinia* virus or cowpox virus were used to vaccinate against smallpox virus (i.e. *Variola*).

Advantages

Live vaccines in general, are more potent immunizing agent compared to killed vaccines, due to the following reasons:

- The live organisms **multiply** in the host and the resultant antigenic dose would be larger than what is administered.
- Live vaccines retain all the immunogenic components (major and minor) of the organisms.

TABLE 20.1: Example of commonly used vaccines

Bacterial	Viral
Live vaccines	
BCG vaccine	Measles vaccine
Typhoral vaccine	Mumps vaccine
Epidemic typhus vaccine	Rubella vaccine
	Live attenuated influenza vaccine
	Chickenpox vaccine
	Oral polio vaccine (OPV, Sabin vaccine)
	Rotavirus vaccine
	Yellow fever 17D vaccine
	Hepatitis A vaccine
	Japanese B encephalitis vaccine (14-14-2 strain)
Killed/inactivated vaccine	
Bacterial	Viral
Typhoid vaccine	Injectable polio vaccine (IPV or Salk vaccine)
Cholera vaccine	Killed influenza vaccine
Pertussis vaccine	Rabies vaccine
Plague vaccine	Hepatitis A vaccine
	Japanese B encephalitis vaccine (Nakayama strain)
Toxoid vaccine	
DT (Diphtheria toxoid) TT (Tetanus toxoid)	
Subunit vaccine	
	Hepatitis B vaccine
	HPV (Human papillomavirus) vaccine
Cellular fraction	
Meningococcal vaccine	
Pneumococcal vaccine	
Haemophilus influenzae type b vaccine	
Combined vaccine	
DPT vaccine (Diphtheria, pertussis and tetanus)	Mumps, measles, rubella (MMR) vaccine
Pentavalent vaccine (DPT + Hib + Hepatitis B)	

Note: Details about individual vaccine is discussed in the respective chapters.

- They are capable of inducing mucosal immunity by stimulating secretory IgA antibody production at the local mucosal sites.

Precautions While Using Live Vaccines

- **Contraindications:** Live vaccines should not be administered in individuals with immunodeficiency diseases or any conditions that supresses the immunity, such as leukemia, lymphoma, malignancies or corticosteroid or any other immunosuppressive drug therapy.
- **Pregnancy** is another contraindication, unless the risk of infection exceeds the risk of harm to the fetus by giving the live vaccine.
- When two live vaccines are required to be given; they should be administered with an interval of at least 4 weeks. Exception is yellow fever vaccine which is given less than 4 weeks after MMR vaccine.
- **Dosage:** Most live vaccines are given in single dose format as effective immunity is achieved with a single dose. Exception is oral polio vaccine (OPV) which is given as multiple doses at spaced intervals to achieve effective immunity.
- **Risk of gaining the virulence:** The attenuation of the live vaccine has to be done in an effective way otherwise there is always a risk of gaining the virulence back again.
- **Storage:** Live vaccines must be stored cautiously to retain effectiveness, especially the OPV and measles vaccine.

Inactivated or Killed Vaccine

It consists of organisms, which are grown in culture under controlled conditions and then killed using methods, such as heat or formaldehyde.

- They are generally safer but less efficacious than live vaccines.
- Compared to the live vaccines, killed vaccines require large doses, adjuvants, and multiple doses to confer immunity. In most cases, a booster dose is also needed.
- Adjuvants increase the immunogenicity of the vaccine antigen (e.g. alum is used as adjuvant in DPT vaccine).
- Killed vaccines are usually administered in subcutaneous or intramuscular routes. The only absolute contraindication is a severe local or general reaction to the previous dose.

Various characteristics of killed and live vaccines are given in Table 20.2.

Toxoid Vaccine

The exotoxins produced by certain bacteria can be detoxicated to form toxoid by treating with acidic pH, formalin or by prolonged storage.

- Toxoid is a form of toxin that loses its virulence property but retains immunogenicity.
- When a toxoid preparation is given as vaccine, it induces formation of neutralizing antibodies that are capable of neutralizing the toxin moiety produced during an infection; rather than acting upon the organism.

TABLE 20.2: Characteristics of killed and live vaccines

Characteristics	Killed vaccine	Live vaccine
Number of doses	Multiple	Single*
Need for adjuvant	Yes	No
Duration of immunity	Shorter	Longer
Effectiveness of protection	Lower	Greater
Mimics natural infection	Less closely	More closely
Immunoglobulins produced	IgG	IgA and IgG
Mucosal immunity	Absent	Induced
Cell-mediated immunity	Poor	Induced
Reverts back to virulent form	No	Possible
Excretion of vaccine virus and transmission to non-immune contacts	No	Possible
Interference by other microorganisms in host	No	Possible
Stability at room temperature	High	Low
Immunodeficiency and pregnancy	Safe	Unsafe

*Exception is oral polio vaccine (OPV), which is given as multiple doses at spaced intervals to achieve effective immunity.

- Examples include diphtheria toxoid (from *Corynebacterium diphtheriae*) and tetanus toxoid (from *Clostridium tetani*).

Extracted or Cellular Fractions Vaccine

Vaccines, in certain instances, are prepared from extracted cellular fractions; examples include meningococcal vaccine, pneumococcal vaccine and *Haemophilus influenzae* type b vaccine—all are prepared from the capsular polysaccharide antigens of the respective organism.

Subunit Vaccines

For certain viruses, only a particular subunit of the virus is necessary to initiate the infection, e.g. hepatitis B surface antigen (HBsAg) is the immunogenic component of hepatitis B virus. So, the subviral component alone can be used as vaccine rather than the whole virus.

- Examples of subunit vaccines include hepatitis B vaccine and human papillomavirus (HPV) vaccine.
- DNA recombinant technology is used for the preparation of such sub viral components. For example, in hepatitis B vaccine preparation, the gene coding for HBsAg is inserted into the chromosome of baker's yeast, so that, with the multiplication of the yeast, the gene of interest would also replicate resulting in production of large quantity of HBsAg which can be used as vaccine.

Combinations

If more than one immunizing agents are included in a vaccine preparation, it is called combined vaccine. The aim of the combined vaccine is to—

- Simplify administration and
- Augment the immunogenicity of the immunogen. For example, in DPT vaccine, the pertussis component acts as an adjuvant, which increases the immunogenicity of both diphtheria toxoid and tetanus toxoid.

Newer Vaccine Approaches

DNA Vaccine

DNA vaccines are experimental at present, have many advantages such as cost effectiveness and mounting a stronger and wider range of immune response.

The small pieces of DNA containing genes from the pathogenic microorganism are injected into the host. The gene of interest gets integrated with the host cell genome and starts transcribing the proteins against which the host mounts an immune response. Several vaccine trials are going on based on DNA vaccines.

Edible Vaccine

The edible vaccine is a new concept introduced recently.

- The gene encoding the orally active antigenic protein is isolated from the pathogen and is transferred to suitable plant bacteria, which are then used to infect a transgenic plant (e.g. banana, potato, etc.).
- The plants infected by the bacteria then start producing the antigen of interest in large scale. The appropriate plant parts having the antigen may be fed raw to animals or humans to bring about immunization.
- The advantages of the edible vaccines are—(1) low cost, (2) ability to produce in large scale, (3) administered orally, (4) induces local immunity, and (5) heat stable.
- **Applications:** The edible vaccines are still under experimental stage; some formulations available include—
  - Transgenic potatoes and tomatoes against diarrheagenic organisms.
  - Edible banana against Norwalk virus.

Cold Chain

"Cold chain" refers to a system of transport, storage, and handling of vaccines, starting at the manufacturer level and ending with the site of administration of the vaccine to the client. The optimum temperature for refrigerated vaccines is between +2°C and +8°C. For frozen vaccines the optimum temperature is –15°C or lower. In addition, protection from light is a necessary condition for some vaccines. Improper cold chain maintenance is one of the

most common causes of vaccine failure; especially oral polio vaccine which is the most sensitive vaccine to heat; must be stored at –20°C.

- Vaccines which must be stored in the freezer compartment are polio and measles vaccines.
- Vaccines which must be stored in the COLD part but never allowed to freeze are—DPT, TT, Td, BCG, hepatitis B, *H. influenzae* type b and diluents.

Vaccine Vial Monitor

Vaccine vial monitor is a tool to monitor the stability/potency of a vaccine and to check the efficiency of cold chain.

It is heat sensitive label lining the vaccine vial. It contains an outer blue circle and an inner white square. With increase of time and temperature, the inner square changes its color gradually from white towards blue, whereas the outer circle is not heat sensitive; it remains blue throughout (Table 20.3 and Fig. 20.1).

TABLE 20.3: Staging of vaccine vial monitor

	Inner square	Outer circle	Vaccine
Stage 1	White	Blue	Can be used
Stage 2	Light blue	Blue	Can be used
Stage 3	Blue	Blue	Discard
Stage 4	Dark blue	Blue	Discard

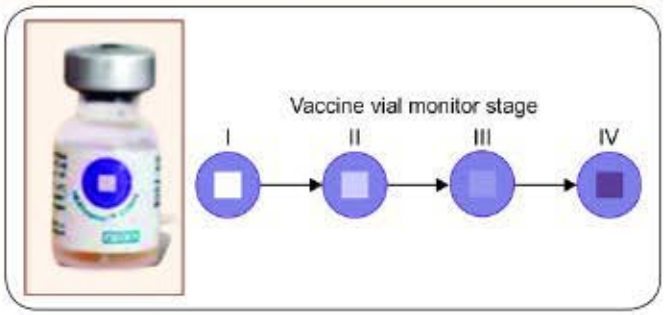

Fig. 20.1: Staging of vaccine vial monitor
(Vaccine is usable up to stages I and II and should be discarded for stages III and IV)

National Immunization Schedule (NIS)

Immunization is one of the most logical and cost effective strategies of any country for the prevention of childhood sicknesses and disabilities and is thus a basic need for all children. The following is the national immunization schedule recommended by the Ministry of Health, Government of India and it includes those vaccines that are given free of cost to all children of our country (Table 20.4).

PASSIVE IMMUNOPROPHYLAXIS (IMMUNOGLOBULINS)

Passive immunoprophylaxis is given in the form of commercially available ready made **immunoglobulins** prepared against the pathogenic microorganism. Unlike

TABLE 20.4: National Immunization Schedule (NIS) for infants, children and pregnant women (India)

Vaccine	When to give	Dose	Route	Site
For Pregnant Women				
TT-1	Early in pregnancy	0.5 mL	Intramuscular	Upper arm
TT-2	4 weeks afterTT-1*	0.5 mL	Intramuscular	Upper arm
TT-Booster	If received 2TT doses in a pregnancy within the last 3 years*	0.5 mL	Intramuscular	Upper arm
For Infants				
BCG	At birth or as early as possible till 1 year of age	0.1 mL (0.05 mL until 1 month age)	Intradermal	Left upper arm
Hepatitis B	At birth or as early as possible within 24 hours	0.5 mL	Intramuscular	Anterolateral side of mid thigh
OPV-0	At birth or as early as possible within the first 15 days	2 drops	Oral	Oral
OPV 1, 2 and 3	At 6 weeks, 10 weeks and 14 weeks	2 drops	Oral	Oral
DPT1, 2 and 3	At 6 weeks, 10 weeks and 14 weeks	0.5 mL	Intramuscular	Anterolateral side of mid thigh
Hepatitis B 1, 2 and 3	At 6 weeks, 10 weeks and 14 weeks	0.5 mL	Intramuscular	Anterolateral side of mid thigh

Contd...

Contd...

Vaccine	When to give	Dose	Route	Site
Measles	9 completed months–12 months (give up to 5 years if not received at 9–12 months age)	0.5 mL	Subcutaneous	Right upper arm
Vitamin A (1st dose)	At 9 months with measles vaccine	1 mL (1 lakh IU)	Oral	Oral
For Children				
DPT booster	16–24 months	0.5 mL	Intramuscular	Anterolateral side of mid thigh
OPV booster	16–24 months	2 drops	Oral	Oral
Measles (2nd dose)	16–24 months	0.5 mL	Subcutaneous	Right upper arm
Japanese encephalitis**	16–24 months with DPT/OPV booster	0.5 mL	Subcutaneous	Left upper arm
Vitamin A*** (2nd to 9th dose)	16 months with DPT/OPV booster. Then one dose every 6 months up to the age of 5 years	2 mL (2 lakh IU)	Oral	Oral
DPT Booster	5–6 years	0.5 mL	Intramuscular	Upper arm
TT	10 years and 16 years	0.5 mL	Intramuscular	Upper arm

* Give TT-2 or booster doses before 36 weeks of pregnancy. However, give these even if more than 36 weeks have passed. Give TT to a woman in labor, if she has not previously received TT.

** SA 14–14–2 vaccine, in selected endemic districts after the campaign.

*** The 2nd to 9th doses of vitamin A can be administered to children 1–5 years old.

vaccines, immunoglobulins act faster, without involvement of host immune apparatus.

Passive immunization is useful in the following circumstances:

- For immunocompromized individuals who cannot synthesize antibodies.
- For postexposure prophylaxis to achieve an immediate effect.

For the treatment of toxin mediated diseases to ameliorate the effect of toxin. Antibiotics cannot neutralize the toxin; hence, they cannot be used for the treatment of toxin mediated diseases.

Passive immunoprophylaxis is available against various microbial diseases given in Table 20.5.

TABLE 20.5: Passive immunoprophylaxis

Immunoglobulin preparations	Source	Indications
Diphtheria antitoxin	Equine	Treatment of respiratory diphtheria
Tetanus immune globulin (TIG)	Equine, Human	Treatment of tetanus as PEP, for people not adequately immunized with tetanus toxoid
Botulinum antitoxin	Equine, Human	Treatment of botulism
Varicella-zoster immune globulin (VZIG)	Human	PEP for immunosuppressed contacts of acute cases or new born contacts
Cytomegalovirus immune globulin (CMV-IG)	Human	PEP in hematopoietic stem cell and kidney transplant recipients
Rabies immune globulin (RIG)	Equine, Human	Treatment of rabies and PEP in people not previously immunized with rabies vaccine
Hepatitis B immune globulin (HBIG)	Human	PEP for Percutaneous or mucosal or sexual exposure Newborn of mother with HBsAg +ve
Hepatitis A immune globulin (HAIG)	Human	Postexposure prophylaxis • Family contacts • Travellers
Rubella	Human	Women exposed during early pregnancy
Measles	Human	Infants or immunosuppressed contacts of acute cases exposed <6 days previously
Rh isoimmunization (RhIG)	Human	**Treatment** Rh-ve mother on delivery of a Rh+ve baby

PEP, Postexposure prophylaxis

IMMUNOHEMATOLOGY

Among the 33 recognized blood group systems, the ABO system is the oldest system to be discovered (Landsteiner, 1900). The other blood group systems include Rh, MN, P, Lutheran, Lewis, Kell, Duffy, Kidd, Diego, Yt, Kg, Dombrock and Colton.

ABO BLOOD GROUP SYSTEM

The ABO blood group system comprises of four blood groups, each is determined by the presence or absence of two antigens A and B on the surface of the red blood cell (RBC) membrane and their corresponding antibodies in

TABLE 20.6: Distribution of ABO antigens and antibodies in RBCs and serum

Blood group	Antigen on RBC	Isoantibodies in serum
A	A	Anti-B
B	B	Anti-A
AB	AB	None
O	None	Anti-A and Anti-B

serum. The principle followed is if a blood group antigen is present on the RBC then the corresponding antibody would be absent in serum. Examples given in Table 20.6.

Natural Isoantibodies

Anti-A and anti-B isoantibodies are called natural antibodies because they are seen to arise without any apparent antigenic stimulation.

They are IgM in nature (pentameric), produced by the age of 6 months and persist thereafter.

ABO System in Other Animals

ABO blood types are also present in some other animals, for example rodents and apes, such as chimpanzees, and gorillas.

Distribution of Blood Groups in India

In India,because of diversity of race, religion and creed, the distribution of blood groups within the population is not uniform. A recent study done in North India had shown that group B is the commonest (35%), follow by group O (30%), A (21%) and AB (14%). Previous south Indian studies had shown blood group O to be the most common. However distribution of ABO blood groups may vary between various geographical areas.

RH BLOOD GROUP SYSTEM

Rh blood group is the most important blood group system in humans after ABO system. It was so named because the antibody against this Rh blood group antigen was first prepared in Rhesus monkey by Landsteiner and Wiener.

- At present, the Rh blood group system consists of 50 defined blood-group antigens, among which the five antigens D, C, c, E, and e are the most important.
- The commonly used terms Rh factor, refer to the D antigen only. Rh positive and Rh negative denote presence or absence of Rh antigen on the surface of RBCs. Unlike ABO system, there are no natural Rh antibodies in our blood.
- In India, about 95% of individuals have Rh positive blood group; the remainder (5%) are Rh negative.
- Rh blood group system has two important clinical applications—(1) its role in blood transfusion, (2) its role in causing hemolytic disease of the newborn (or Erythroblastosis fetalis).

Erythroblastosis Fetalis

When the mother is Rh-negative and the father is Rh-positive, the fetus can inherit the Rh factor from the father. This makes the fetus Rh-positive.

- During delivery, the Rh positive blood may be passed into maternal circulation.
- The mother being Rh-negative, may develop antibodies to an Rh-positive fetal RBCs. However, as anti-Rh antibodies are produced only after exposure to Rh-antigen (from Rh-positive fetus to Rh-negative mother or mismatched transfusion) and take some time to generate anti-Rh IgG which can cross the placenta; hence, maternal Rh antibodies fail to lyse fetal RBCs during the first Rh-incompatible pregnancy.
- During the subsequent pregnancies with a Rh positive fetus, the Rh antibodies being IgG in nature, can cross the placenta from mother to fetus and can destroy the fetal RBCs.
- This condition is called **hemolytic disease of newborn**. It can become severe enough to cause serious illness, brain damage, or even death of the fetus or newborn.

OTHER BLOOD GROUP SYSTEMS

In routine transfusion practice, only the ABO and Rh antigens are relevant. Proper matching of ABO and Rh groups should be carried out before transfusing the blood unit. The other blood group antigens are too weak.

SAFE BLOOD TRANSFUSION PRACTICES

Safe blood transfusion practices require that the following conditions are satisfied in choosing a donor:

- The recipient's plasma should not contain any antibodies that will damage the donor's RBCs.
- The donor plasma should not have any antibodies that will damage the recipient's RBCs.
- The donor red cells should not have any antigen that is lacking in the recipient RBCs. If the transfused cells possess a 'foreign antigen' it will stimulate an immune response in the recipient.

Selection of Blood Group for Blood Transfusion

Ideally, the donor and recipient should belong to the same ABO group. However in emergency situations, O blood group can be used for transfusion for any other ABO group and individuals with AB blood group can receive blood unit with any blood group.

Contd...

Contd...

- **Universal donor:** Individuals with 'O' blood group are called as universal donors because they do not possess either A or B antigen; hence, they are generally safe.
  - The anti-A and anti-B antibodies in the transfused O blood group are diluted in recipient's serum, do not ordinarily cause any damage to the red cells of the A or B blood group recipients.
  - ***Dangerous O group*:** It is observed that if the anti-A and anti-B antibody titers are high (1:200 or above) in the serum of the individuals with O blood group; then transfusion of such blood may result in damage to recipient's RBCs. This type of O blood group is called as the dangerous O blood group and it should not be used for transfusion.
- **Universal recipients:** Individuals with AB blood group do not have both A and B antibodies in serum; therefore, they can receive any other blood group. Hence, they are called as universal recipients.

TRANSFUSION REACTIONS

Transfusion reactions are the complications of blood transfusion; which may be of two types—immunological and nonimmunological.

Immunological Complications

Following are the immunological reactions that can take place after an incompatible blood transfusion.

- **Acute hemolytic reactions:** They are rare, occurs as a result of mismatched blood transfusion. The RBCs undergo intravascular hemolysis or they may be coated by antibodies and engulfed by phagocytes, removed from circulation and subjected to extravascular lysis.
  - Symptoms include fever, chills, chest pain, back pain, haemorrhage, increased heart rate, dyspnea, hypotension and rarely kidney injury.
  - When transfusion reaction is suspected, transfusion should be stopped immediately, and blood should be sent for tests to evaluate for presence of hemolysis. Treatment is supportive.
- **Delayed hemolytic reactions:** They may occur in some cases of mismatched blood transfusion. They mediate the same mechanism as seen in acute hemolytic reactions, but they are milder and occur late.
- **Febrile nonhemolytic reactions:** They are the most common type of transfusion reactions and occur due to the release of inflammatory chemical signals by WBCs present in stored donor blood.
- **Allergic reactions:** They occur when the recipient has preformed antibodies to certain chemicals in the donor blood, and they do not require prior exposure to blood transfusions.
- **Post-transfusion thrombocytopenia:** It may occur following transfusion containing platelets possessing surface protein Human platelet antigen-1a (HPA-1a).
- **Transfusion-associated acute lung injury (TRALI):** It is a rare complication, characterized by acute respiratory distress; probably mediated by anti-HLA antibodies. It is more common in pregnancy.

Nonimmunological Complications

These iron overload and various transfusion-transmitted infections.

Transfusion-transmitted infections

The most important nonimmunological complication is transmission of infectious agents during blood transfusion. These may include viruses, bacteria and protozoa. HIV and hepatitis viruses are of great concern among all the infectious agents associated with blood transfusion. List of various infectious agents transmitted via blood transfusion is as follows:

- **Viruses**
  - Human immunodeficiency viruses (HIV)
  - Hepatitis B, C and rarely D viruses
  - Cytomegalovirus (CMV)
  - Human T-Lymphotropic Virus
- **Bacteria**
  - *Treponema pallidum*
  - *Leptospira interrogans*
  - *Borrelia burgdorferi*
- **Protozoa**
  - *Plasmodium* species
  - *Babesia* species
  - *Leishmania donovani*
  - *Toxoplasma gondii*
  - *Trypanosoma cruzi*

EXPECTED QUESTIONS

I. Write short notes on:

1. Live vaccines vs. killed vaccines
2. National Immunization Schedule
3. Passive immunoprophylaxis
4. Transfusion reactions

II. Multiple Choice Questions (MCQs):

1. All of the following are live attenuated vaccines except:

a. MMR
b. Yellow fever 17D vaccine
c. Salk polio vaccine
d. Sabin polio vaccine

2. Which of the following infectious agents can be transmitted through blood transmission?

a. HIV
b. *Treponema pallidum*
c. *Toxoplasma gondii*
d. All of the above

CHAPTER 21

Staphylococcus

Chapter Preview

- Introduction
- Staphylococcus aureus
- Coagulase negative Staphylococcus (CoNS)

INTRODUCTION

Gram-positive cocci are classified into two families—Micrococcaceae and Streptococcaceae, differentiated by the catalase test. Micrococcaceae are catalase positive, gram-positive cocci arranged in tetrads or clusters; whereas Streptococcaceae are catalase negative gram-positive cocci, arranged in pairs or chains.

Family Micrococcaceae comprises of four genera—*Micrococcus, Stomatococcus, Planococcus* and *Staphylococcus*.

- *Micrococcus* species are skin commensals, usually not associated with human infections. They are 1–1.8 μm size, arranged in tetrads. As they are obligate aerobes, they show oxidative pattern in Hugh and Leifson's oxidative-fermentative (OF) test.
- *Planococcus* and *Stomatococcus* are not pathogenic to man.
- *Staphylococcus* species are arranged in clusters, show fermentative pattern in oxidative fermentive test.
  - Among *Staphylococcus* species, *S. aureus* is the most pathogenic; it produces an enzyme coagulase which forms the basis of coagulase test.
  - Whereas, other species do not produce coagulase and are called as coagulase-negative *Staphylococcus* (CoNS). They are rarely pathogenic to man; may cause infections in immunocompromised patients.
  - *S. epidermidis* is the most common CoNS infecting man, followed by *S. saprophyticus, S. lugdunensis, S. schleiferi, S. haemolyticus* and *S. warneri*.

History

Staphylococcus was first observed in pus by von Recklinghausen (1871) and was first cultured in liquid medium by Louis Pasteur (1880).

It was named as *Staphylococcus* (in Greek, *Staphyle* means 'bunch of grapes' and *kokkos* means berry) by Sir Alexander Ogston (1880). Rosenbach (1884) named two species of staphylococci based on pigmentation of colonies as *S. aureus* (golden yellow colonies) and *S. albus* (white colonies). Later Passet (1885) named a third species as *S. citreus* (lemon yellow colonies).

STAPHYLOCOCCUS AUREUS

Staphylococcus aureus is catalase positive, coagulase positive, facultative anaerobe, non-motile, non-sporing and occasionally capsulated.

- They are spherical cocci, about 1 μm in diameter, arranged in grape-like clusters. This arrangement is due to cell-division in *S. aureus* occurs in multiple planes with daughter cells remaining close together.
- It produces golden yellow pigmentation on nutrient agar and β hemolytic colonies on blood agar.
- *S. aureus* is the most virulent species among staphylococci; produces infections which range from localized pyogenic infections to life-threatening systemic infections in man.
- Its importance as human pathogen is greatly enhanced especially in hospital environment because of its ability to develop drug resistance.

Virulence Factors

S. aureus possesses an array of virulence factors as listed in Table 21.1.

Cell Wall Associated Factors

Like most gram-positive bacteria, the cell wall of *Staphylococcus* consists of a thick peptidoglycan layer and teichoic acid. *S. aureus* has additional factors in the cell wall, such as protein A and clumping factor.

TABLE 21.1: Virulence factors of *Staphylococcus aureus*

Cell wall associated factors
Peptidoglycan Teichoic acid Cell surface adhesins—e.g. clumping factor Protein A
Toxins
Membrane active toxins ▪ Hemolysins—α, β, γ, δ ▪ Leukocidin (or panton valentine toxin)
Epidermolytic toxin (exfoliative toxin) Enterotoxins Toxic shock syndrome toxin
Extracellular enzymes
Coagulase Heat stable thermonuclease Deoxyribonuclease Staphylokinase (fibrinolysin) Others—hyaluronidase, lipase, and protease

TABLE 21.2: Hemolysins of *Staphylococcus aureus* and their activity

Hemolysins	Activities
α-hemolysin	It is inactivated at 70°C but again reactivated paradoxically at 100°C (This is because at 60°C α-hemolysin combines with a heat labile inactivator which gets denatured at 100°C). ▪ It possesses lethal, leukocidal, dermonecrotic, cytotoxic and neurotoxic activities. ▪ It lyses rabbit RBCs, but is less active against sheep and human RBCs.
β-hemolysin	It is sphingomyelinase in nature: ▪ Lyses sheep RBC, but not human or rabbit RBC. ▪ Exhibits **hot-cold phenomenon**, i.e. hemolysis starts at 37°C but becomes evident only after chilling.
γ-hemolysin	▪ It has three protein fragments which act together along with leukocidin to exhibit hemolytic activity. ▪ It lyses rabbit, sheep and human RBCs.
δ-hemolysin	▪ It has detergent like (surfactant) action. ▪ It lyses rabbit, sheep, horse and human RBCs. ▪ It is also lethal, leukocidal and dermonecrotic.

Peptidoglycan

Similar to other gram-positive bacteria, the peptidoglycan layer of *Staphylococcus* is thicker (15–80 nm, up to 100 layers thick).

- It confers rigidity to the cell wall and maintains the shape.
- It induces inflammatory response and also has endotoxin-like activity.

Teichoic Acid

It is made up of ribitol phosphate polymers, helps in adhesion of cocci to mucosal surfaces and inhibits opsonisation.

Cell Surface Adhesins

- Clumping factor/bound coagulase—it is a fibrinogen binding adhesin; responsible for slide coagulase reaction.
- Fibronectin binding adhesin
- Collagen-binding adhesin

Protein A (SpA)

It is a 42 kDa polypeptide, encoded by *spa* gene. It is present on 90–99% of human *S. aureus* strains (especially the Cowan I strains).

- Protein A has many **biological properties**, such as anti-complementary, chemotactic, mitogenic, inhibition of opsonization and induction of platelet damage.
- **Mediates coagglutination reaction:** Protein A binds to Fc region of any IgG antibody, leaving Fab region free which binds to the corresponding antigen present in clinical samples (Described in detail in Chapter 12).

Microcapsule

Some strains of *S. aureus* have polysaccharide microcapsule, which inhibits phagocytosis by neutrophils. The capsular polysaccharides are zwitterionic—i.e. they have both negative and positive charges, which is a feature that is critical for abscess formation.

Toxins

Membrane Active Toxins

Hemolysins

S. aureus produces four distinct hemolysins—α, β, γ and δ hemolysins. They are membrane damaging toxins, act on red blood cells (RBCs) leading to hemolysis. They differ from each other by their action on RBCs of different animals, their lethal, dermonecrotic and leucocidal activity (Table 21.2).

Leukocidins/Panton Valentine Toxin

It is also called as panton valentine (PV) toxin (after its discoverer).

- It has two components F (fast) and S (slow) based on their migration on carboxymethyl cellulose column.
- Both the fragments act synergistically with γ-hemolysin to damage leukocytes, RBCs and macrophages.
- **Synergohymenotropic toxins:** γ-hemolysin and PV toxin are called as synergohymenotropic toxins. Because they are not active individually, but in combination they are capable of producing hemolytic and leukocidal activity. There are six combinations possible by the interaction between three fragments of γ-hemolysin with the two fragments of PV toxin.

- PV toxin is expressed on MRSA (methicillin-resistant *Staphylococcus aureus*) strains, which are associated with the community acquired infections.

Epidermolytic/Exfoliative Toxin (ET)

This toxin is responsible for staphylococcal scalded skin syndrome (SSSS).

- It comprises of two proteins—ET-A (chromosomal, heat stable) and ET-B (plasmid coded, heat labile).
- Staphylococcal scalded skin syndrome (SSSS) often occurs in newborns and children, more often than adults.
- Illness may vary from localized tender blisters and bullae formation to exfoliation and separation of outer epidermal layer leaving denuded underlying skin (the later is called as Nikolsky's sign).
- The mucous membranes are usually spared.
- Severe form in a newborn is called as Ritter's syndrome; characterized by fever, lethargy, and irritability with poor feeding.
- Milder forms—pemphigus neonatorum and bullous impetigo.
- Epidermolytic toxin producing strains belong to *S. aureus* bacteriophage group II.

Enterotoxin

Enterotoxin is expressed by nearly 50% of *S. aureus* strains and is responsible for staphylococcal food poisoning.

- It is a **preformed toxin** (secreted in food before consumption) so that it can act rapidly. As a result, the **incubation period** is short (1–6 hours).
- **Site of action:** The toxin stimulates the vagus nerve and the vomiting center of the brain. It also appears to stimulate the intestinal peristaltic activity.
- **Symptoms:** Staphycoccal food poisoning is characterized by nausea, vomiting, occasionally diarrhea, hypotension, and dehydration; however, there is no fever. Symptoms generally resolve within 8–10 hours.
- **Most common source** of infection is a food handler, who is a carrier of *S. aureus*. There is no secondary spread.
- **Most common food items** involved are milk products, bakery food,custards, potato salad, or processed meats.
- It is a heat stable toxin and is resistant to gastric juice.
- **Serotyping:** Enterotoxins can be typed into many serotypes (A–E, G–I, R–T and V).
  - Type A is most common to cause food poisoning.
  - Serotype-F does not cause food poisoning; but causes toxic shock syndrome.
  - Serotype-J, Q and U are enterotoxin—like toxins.
- *S. aureus* enterotoxins are also responsible for some cases of pseudomembranous colitis following use of broad spectrum antibiotics.
- **Detection of enterotoxin** in food is carried out by ELISA or latex agglutination test or by detecting enterotoxin gene by multiplex PCR (polymerase chain reaction).
- Treatment is entirely supportive by correcting fluid and electrolyte imbalance.

Toxic Shock Syndrome Toxin (TSST)

This toxin is responsible for toxic shock syndrome (TSS). It has two subtypes—TSST-1 and TSST-2.

- TSST-1 is actually a staphylococcal enterotoxin. Enterotoxin F or pyrogenic exotoxin C is the most common type of TSST-1; rarely enterotoxin-B or C may also be associated.
- TSST producing strains belong to *S. aureus* bacteriophage group I.
- **Risk factors:** Initially, toxic shock syndrome was reported from women using highly absorbent vaginal tampons during menstruation. Subsequently, TSS has been reported from both men and non-menstruating women as a complication of staphylococcal abscesses, osteomyelitis and post-surgical wound infection.
- **Pathogenesis:** TSST-1 gets absorbed into circulation from the tampons; then being a superantigen it stimulates the T-cells non-specifically (by binding to Vβ region of T-cell receptor) causing excessive production of cytokines which leads to a potentially fatal multisystem disease. (Both TSST and enterotoxin are examples of superantigens, detail described in Chapter 10).
- **Clinical features:** Patients present with fever, hypotension, mucosal (conjunctival) hyperemia, vomiting, diarrhea, confusion, myalgia, abdominal pain and erythematous rashes which desquamate later. Subsequently, there is rapid involvement of the other organs such as liver, kidneys, gastrointestinal tract (GIT) and/or central nervous system (CNS).
- Anti-TSST antibodies usually appear in the convalescent stage, they are protective in nature. TSS is more severe if anti-TSST antibodies fail to appear.
- **Diagnosis:** Detection of TSST can be done by latex agglutination test and enzyme immunoassay. PCR based assays are available for detection of TSST genes 1 and 2. Other findings may include altered liver/kidney function tests and low platelet count.

TREATMENT **Toxic shock syndrome**

Clindamycin is the preferred drug for TSS (as it reduces the toxin synthesis). It is given along with semisynthetic penicillin or vancomycin.

Extracellular Enzymes

Coagulase

The unique feature of *S. aureus* is that, it secretes coagulase enzyme which brings about clotting or coagulation of plasma.

TABLE 21.3: Differences between tube coagulase and slide coagulase test

Tube coagulase	Slide coagulase
Due to coagulase enzyme	Due to clumping factor
Requires CRF in plasma	Does not require CRF in plasma
Done in tube	Done on slide
Positive if clot is formed	Positive if clumps are formed
Coagulase enzyme has eight serotypes	Clumping factor has one serotype
S. lugdunensis gives a negative result	*S. lugdunensis* gives a positive result
Both tube and slide coagulase positive for *S. aureus*, *S. hyicus*, and *S. intermedius*	

Abbreviation: CRF, coagulase reacting factor

- Coagulase enzyme combines with a plasma protein called CRF (coagulase reacting factor), and together they activate prothrombin, which in turn, converts fibrinogen to fibrin.
- This is the basis of tube coagulase test. This has to be differentiated from slide coagulase test, which is mediated by clumping factor (Table 21.3).
- Coagulase can react with rabbit or human plasma; but does not clot with guinea pig plasma as it lacks CRF.
- **Subtypes:** Coagulase enzyme is of 8 antigenic types (A–H). **Type-A** is the most common type secreted by human strains of *S. aureus*.

Other Enzymes

- Heat stable thermonucleases and DNase (deoxyribonuclease) are the enzymes that are specific to *S. aureus*; not produced by any other staphylococci species.
- Staphylokinase (fibrinolysin) breaks down fibrin clots and may facilitate the spread of infection.
- Hyaluronidase breaks down the connective tissue network.
- Lipases and phospholipases breakdown the lipids.

Pathogenesis

Pathogenesis of *S. aureus* involves the following steps:

- **Colonization:** *S. aureus* colonizes on various body surfaces, such as anterior nares, axilla and perineal skin.
- **Introduction into the tissue:** Organisms are introduced into the tissues as a result of minor abrasions or instrumentation. Then they adhere to the tissue surfaces; which is mediated by various adhesins, e.g. clumping factor.
- **Invasion**: *S. aureus* can invade into the tissues by elaborating enzymes, such as serine proteases, hyaluronidases, thermonucleases and lipases.
- **Evasion of host defense mechanisms**: *S. aureus* exhibits various immune evasion mechanisms, such as:
  - Anti-phagocytic activity mediated by microcapsule and protein A.
  - Inhibition of leucocyte migration (by chemotaxis inhibitory protein of staphylococci).
  - Intracellular survival inside the endothelial cells (by formation of small colony variants).
- **Metastatic spread:** Finally, *S. aureus* spreads to various distant sites by hematogenous spread.

Clinical Manifestation

Staphylococcus aureus is a pluripotent pathogen, causing various diseases through both toxin-mediated and non-toxin-mediated mechanisms. It is responsible for both nosocomial and community-based infections that range from relatively minor skin and soft tissue infections to life-threatening systemic infections (Table 21.4).

Epidemiology

Staphylococcus aureus is a part of normal human flora. About 25–50% of healthy population are carriers of *S. aureus*, colonizing the organism persistently or transiently.

- **Most common site(s)** of colonization are anterior nares followed by skin (abraded), vagina, axilla, perineum, and oropharynx. These colonization sites serve as a reservoir for future infections.
- The rate of colonization is higher among insulin-dependent diabetics, HIV-infected patients, patients undergoing hemodialysis, and individuals with skin damage.
- Overall, *S. aureus* is a leading cause of nosocomial infections. In hospitals, the health care professionals are the potential carriers of *S. aureus*. Hospital strains are often multidrug resistant, spread to patients either from hospital staff/other patients/environment or also from patient's own endogenous flora.
- *S. aureus* is the most common cause of surgical site wound infections and a leading cause of primary bacteremia.
- In the community, *S. aureus* remains as an important cause of skin and soft tissue infections, respiratory infections and infective endocarditis (among intravenous drug users) (Fig. 21.1).

Fig. 21.1: Staphylococcal cellulitis

Source: Public Health Image Library, ID# 4647/CDC, Atlanta (*with permission*)

TABLE 21.4: Clinical spectrum of *Staphylococcus aureus* infections

Skin and soft tissue infections

S. aureus is one of the most common cause of various skin and soft tissue infections such as:
- **Folliculitis** (infection of hair follicles)
- **Furuncle (boil):** Painful pustular lesion in moist regions due to infection of the hair follicle
- **Carbuncle:** Severe, painful lesion in the lower neck region, extending to the deeper subcutaneous tissue
- Mastitis and breast abscess (in nursing mothers)
- **Impetigo:** It mainly occurs in children, usually appears as red sores on the face, that bursts and develops into **honey-colored crusts**
- Surgical site wound infections
- Cellulitis (inflammation of skin and subcutaneous tissue) (Fig. 21.1)
- **Hidradenitis suppurativa:** A recurrent follicular infection in areas rich in apocrine glands, such as the axilla
- **Botryomycosis:** It is mycetoma-like condition, characterized by subcutaneous swelling, sinuses, and discharge containing granules (Described in Chapter 52).

Predisposing factors to *S. aureus* cutaneous infections are—chronic skin conditions (e.g. eczema), skin damage (trauma, injections) or poor personal hygiene.

Musculoskeletal infections

S. aureus is the most common cause of various conditions such as:
- Septic arthritis (most commonly involved joints are knees, shoulders, hips, and phalanges)
- Osteomyelitis (most commonly affected site in children is long bones and in adults is vertebrae)
- **Pyomyositis (skeletal muscle infection):** In tropics and HIV infected people
- **Abscess:** Psoas abscess and epidural abscess

Respiratory tract infections

- Ventilator associated pneumonia in adults
- Septic pulmonary emboli
- Post viral pneumonia (e.g. influenza)
- Empyema and Pneumothorax
- Pneumatocele (shaggy, thin-walled cavities in lungs) in neonates: *S. aureus* is the most common cause.

Bacteremia and its complications

- Sepsis, septic shock
- Central line associated blood stream infection
- Metastatic foci of infection involving kidney, joints, bone and lung
- Infective endocarditis:
  - Native-valve endocarditis—*S. aureus* is the most common cause
  - Prosthetic-valve endocarditis
  - Intravenous drug use associated endocarditis—*S. aureus* is the most common cause.

UTI (Urinary tract infection)

- Staphylococcal UTI and pyelonephritis usually occur secondary to bacteremia.
- Rarely UTI is seen following instrumentation and insertion of catheter or implants.

Toxin-mediated illnesses (Described earlier)

S. aureus causes the following toxin mediated diseases (as described earlier):
- Toxic shock syndrome
- Food poisoning
- Staphylococcal scalded-skin syndrome

Infections associated with CA-MRSA (Community associated methicillin-resistant *Staphylococcus aureus*)

While skin and soft tissues are the most common sites for CA-MRSA strains; 5–10% of strains are invasive and can cause various invasive infections, such as:
- Necrotizing pneumonia
- Sepsis with Waterhouse-Friderichsen syndrome or purpura fulminans (*S. aureus* is rare cause; most commonly caused by meningococcus).
- Necrotizing fasciitis (*S. aureus* is a rare cause, *Streptococcus pyogenes* is the most common cause)

LABORATORY DIAGNOSIS — *Staphylococcus aureus*

- **Direct smear microscopy:** Gram-positive cocci in clusters and pus cells
- **Culture**
  - Nutrient agar—golden yellow pigmented colonies
  - Blood agar—colonies with narrow zone of β-hemolysis
  - Selective media—such as mannitol salt agar, salt milk agar and Ludlam's medium
- **Culture smear microscopy:** Gram-positive cocci in clusters
- **Biochemical identification**
  - Catalase test-positive

  Tests differentiating *S. aureus* (gives a positive result) from CoNS (gives a negaitive result):
  - Coagulase test (slide and tube)-positive
  - Heat stable thermo nuclease test-positive
  - DNase test-positive
  - Phosphatase test-positive
  - Mannitol sugar is fermented
  - Black colored colonies on potassium tellurite agar
  - Gelatin liquefaction-positive
  - Protein A detection
- **Typing methods**
  - Phenotypic methods: bacteriophage typing and antibiogram typing
  - Genotypic methods such as PCR-RFLP
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Sample Collection

It depends on the nature of the lesion (Table 21.5).

Direct Smear Microscopy

Gram staining of pus or wound swab reveals pus cells with gram-positive cocci in clusters (Fig. 21.2). However, direct microscopy is of no value when *S. aureus* is a part of normal flora in the sample (e.g. sputum or feces).

TABLE 21.5: Specimen collection for *Staphylococcus aureus* infections

Infection	Specimen
Suppurative lesions	Pus, wound swab
Respiratory Infections	Sputum
Urinary tract infection	Mid stream urine
PUO, bacteremia	Blood
Food poisoning	Feces, vomitus and food
Carriers	Nasal and perianal swab

Abbreviation: PUO, pyrexia of unknown origin

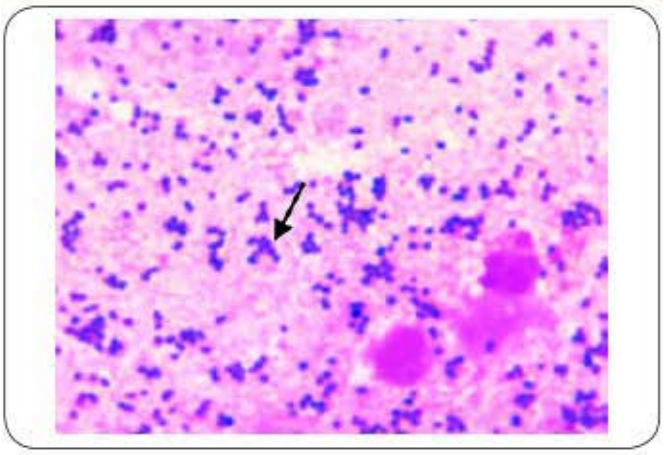

Fig. 21.2: Direct smear showing gram-positive cocci in clusters and pus cells (arrow showing)

Culture

Specimens are inoculated onto various media and incubated overnight at 37°C aerobically. The colony morphology is observed as follows:

- **Nutrient agar:** Colonies are 1–3 mm in size, circular, smooth, convex, opaque and easily emulsifiable. Most strains produce golden yellow non diffusible **pigments** (made up of β carotene) (Fig. 21.3A). Pigmentation can be enhanced by prolonged aerobic incubation at 22–25°C or by incorporation of 1% glycerol or milk in the medium or if grown in fatty medium (Tween agar). Grown anaerobically, colonies are smaller and grayish in color.
- **Nutrient agar slope:** It produces confluent growth, looks like oil paint appearance.
- **Blood agar:** Colonies are similar to that on nutrient agar, in addition surrounded by a narrow zone of β hemolysis (best observed in sheep blood agar) (Fig. 21.3B).
- **MacConkey agar:** Small pink colonies are produced due to lactose fermentation.
- **Liquid medium (e.g. peptone water):** It produces uniform turbidity.
- **Selective media:** They are useful when staphylococci are expected to be scanty or outnumbered by other bacteria in the sample (e.g. swabs from carriers, feces). Salt is added to the media, as it is inhibitory to other bacteria but not to staphylococci. Examples include:
  - Mannitol salt agar contains nutrient agar with 7.5% NaCl and phenol red as an indicator. All staphylococci can grow at 7.5% salt; however, *S. aureus* produces yellow colored colonies due to mannitol fermentation (Fig. 21.3C).
  - Salt milk agar contains nutrient agar, 6.5% NaCl and 10% skimmed milk.
  - Ludlam's medium contains lithium chloride and tellurite.

Figs 21.3A to C: A. Nutrient agar—shows golden-yellow pigmented colonies; **B.** Blood agar—*S. aureus* shows narrow zone of beta hemolysis surrounding the colonies; **C.** Mannitol salt agar shows yellow colored colonies of *S. aureus* due to fermentation of mannitol

Culture Smear Microscopy

Gram staining from the colonies shows gram-positive cocci (1 μm), arranged in clusters. Hanging drop reveals non-motile cocci.

Biochemical Tests for Identification

Catalase Test

All members of Micrococcaceae (staphylococci and micrococci) are catalase positive, which differentiates them from Streptococcaceae (catalase negative).

Hugh and Leifson Oxidative Fermentative Test

This test differentiates staphylococci (shows fermentative pattern) from micrococci (shows oxidative pattern).

Tests to Differentiate *S. aureus* from CoNS

S. aureus can be differentiated from CoNS (coagulase-negative staphylococci) by various tests (as described in the laboratory diagnosis box), of which the coagulase test is the most important.

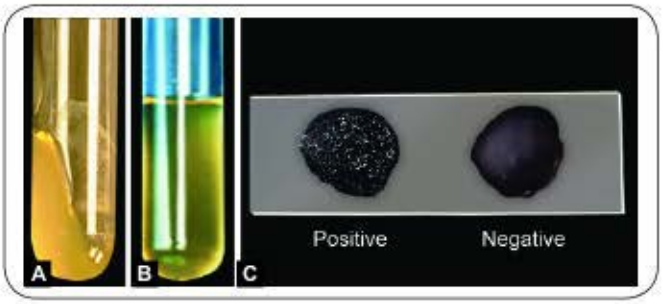
Coagulase Test

It is the most commonly used biochemical reaction for identification of *S. aureus*.

Tube Coagulase Test

It detects free coagulase.

- **Procedure:** Colony of *S. aureus* is emulsified in 1 mL of diluted plasma (1:6) in a test tube and incubated at 37°C, preferably in a water bath for up to 4 hours.
- **Positive test** is indicated by formation of a clot that does not flow when the test tube is tilted (Fig. 21.4A). Any degree of clot formation is considered as positive.
- The **negative tubes** (no clot formation) should be incubated overnight and re-examined as some strains may produce a delayed clot (Fig. 21.4B).
- **False-positive**: Citrated plasma should not be used as some bacteria (e.g. *Pseudomonas*) may utilize citrate and give a false positive result. Heparin or EDTA are the preferred anticoagulants.



Figs 21.4A to C: Coagulase test: **A.** Tube coagulase test (positive); **B.** Tube coagulase test (negative); **C.** Slide showing coagulase test

Slide Coagulase Test

It detects clumping factor (i.e. bound coagulase).

- **Procedure:** A colony of *S. aureus* is emulsified with a drop of normal saline on a clean slide to form a milky white suspension. Then a drop of undiluted plasma is added and mixed properly.
- Positive result is indicated by formation of coarse clumps (Fig. 21.4C).
- Results should be confirmed by the tube coagulase test as ≥15% of *S. aureus* strains (including some MRSA) give false-negative results. At the same time, few CoNS, such as *S. lugdunensis* give a positive result.

DNase Test

On DNA agar, a clear halo is produced surrounding the colonies of *S. aureus*, due to its ability to digest DNA.

Phosphatase Test

This test is positive for *S. aureus, S. epidermidis* and *S. xylosus*. Organism is inoculated on phenolphthalein diphosphate containing media and later the colonies grown are exposed to ammonia vapor (see below).

S. aureus → splits phenolphthalein diphosphate in the media → releases free phenolphthalein → reacts with ammonia vapors → colonies turn pink.

Typing of S. aureus

Typing of *S. aureus* to subspecies level is done for epidemiological purpose to trace the source of infection. It is especially useful in outbreaks such as food poisoning affecting a larger community. Typing methods include both:

- Phenotypic methods—bacteriophage typing and antibiogram typing.
- Genotypic methods such as PCR–RFLP (restricted fragment length polymorphism), ribotyping, PFGE (pulse field gel electrophoresis) and sequence based typing.

Bacteriophage Typing

Strains of *S. aureus* can be further differentiated into subspecies level based on their susceptibility to bacteriophages.

Procedure

Pattern method of phage typing is followed (Fig. 21.5).

The test strain is inoculated as lawn culture on a nutrient agar → drops of routine test dose of known set of different phages are spot inoculated → zone of lysis will be produced in those areas where the test strain is susceptible to the phages applied.

- The phage type is designated according to the capability of different phages to lyse the strain.
- For example, if a strain is lysed by phages 29, 52A, 79, but not by other phages, then it is designated as phage type 29/52A/79.
- National reference centre for phage typing is located in Maulana Azad Medical College, New Delhi.
- **Phage type 80/81** is most commonly associated with outbreaks in hospitals. It is known as epidemic strain of *S. aureus*.

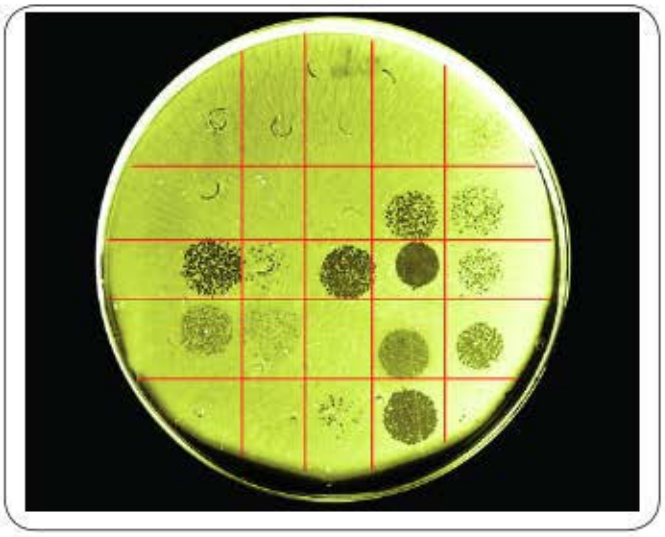


Fig. 21.5: Pattern method of bacteriophage typing

Antimicrobial Susceptibility Test

As *S. aureus* develops resistance to antibiotics readily, drugs should be prescribed according to the antimicrobial susceptibility test done on Mueller Hinton agar.

Drug Resistance in *S. aureus* (Resistance to β lactam antibiotics)

Staphylococcus aureus shows resistance to β lactam antibiotics in various ways:

Production of β Lactamase Enzyme

β lactamase or penicillinase enzymes cleave the β lactam rings, and there by organism producing this enzyme develops resistance to β lactam antibiotics.

- This resistance is **plasmid coded**, can be transferred between *S. aureus* strains by **transduction**.
- It is produced by >90% of strains of *S. aureus*.
- This resistance can be overcome by addition of β lactamase inhibitors such a clavulanic acid or sulbactam.

By Alternation of Penicillin Binding Protein (PBP)

It is shown by MRSA strains of *S. aureus*.

TREATMENT — ***Staphylococcus aureus***

Since *S. aureus* rapidly develops drug resistance, antibiotics should be cautiously chosen.

Parenteral therapy for serious infections

Sensitive to penicillin	**DOC:** Penicillin G
Sensitive to methicillin	**DOC:** Nafcillin or oxacillin
Resistant to methicillin (MRSA)	**DOC:** Vancomycin (15–20 mg/kg bd) **Alternate drugs:** • Teicoplanin • Daptomycin (for endocarditis and complicated skin infections) • Linezolid • Quinupristin/dalfopristin • Ceftobiprole

Empirical therapy (if MRSA status not yet known): Vancomycin with or without an aminoglycoside (vancomycin is indicated only if MRSA risk is high or condition is serious, e.g. cardiac implant).

Oral therapy for skin and soft tissue infections

Sensitive to methicillin	• Dicloxacillin • Cephalexin/cefazolin
Resistant to methicillin (MRSA)	Clindamycin **Alternate drugs:** Cotrimoxazole, doxycycline, Linezolid

Abbreviations: DOC, drug of choice; bd, twice a day

Methicillin-resistant Staphylococcus aureus (MRSA)

Methicillin resistant in *S. aureus* is mediated by a chromosomally coded gene called ***mec A gene***, which alters penicillin-binding protein (PBP) present on *S. aureus* cell membrane to PBP-2a.

- PBP is an essential protein needed for cell wall synthesis of bacteria. β lactam drugs bind and inhibit this protein, there by inhibit the cell wall synthesis.
- The altered PBP2a of MRSA strains has less affinity for β lactam antibiotics; hence, MRSA strains are resistant to all β lactam antibiotics.
- **Borderline oxacillin resistant *S. aureus* (BORSA) strains:** Occasionally a non-mec A gene mediated low level resistance to oxacillin is observed in some strains of *S. aureus*. This is believed to be due to hyperproduction of β lactamase.
- There is an increasing trend of MRSA rate over last few decades. Though it varies from place to place, overall about 30-40% strains of *S. aureus* are MRSA.

Types of MRSA

MRSA are either community or hospital associated (Table 21.6).

Detection of MRSA

- Antimicrobial susceptibility test: Disc diffusion test can be done by using **cefoxitin** or oxacillin discs. Cefoxitin is the recommended disc to be used. If oxacillin disc is used, then certain conditions to be maintained such as—using media containing 2-4% NaCl, incubation at 30°C and full 24 hours incubation.
- Oxacillin screening agar: Adding oxacillin 6 μg/ml and NaCl (2-4%) to the medium.
- PCR detecting *mecA* gene

TABLE 21.6: Types of MRSA

Community associated MRSA (CA-MRSA)	Hospital associated MRSA (HA-MRSA)
These strains express *mecA* gene subtype IV, V, VI.	These strains express *mecA* gene subtype I, II, III.
They are usually more virulent and express several toxins such as Panton Valentine (PV) toxin.	They are multidrug resistant (but their virulence is relatively low).
They cause invasive skin and soft tissue infections such as necrotizing fasciitis (Table 21.4).	They cause perioperative wound infections in hospitals and nosocomial outbreaks (hospital staff are the major carries).

Note: CA-MRSA and HA-MRSA terminologies are becoming artificial now a days; as many CA-MRSA strains have been isolated in hospitals and vice versa.

TREATMENT — MRSA

- Vancomycin is the drug of choice for MRSA.
- Alternate drugs include—teicoplanin, linezolid, daptomycin and quinupristin/dalfopristin.
- However, even drugs such as tetracycline, erythromycin or cotrimoxazole may also be effective in non life-threatening infections.
- Antimicrobial susceptibility testing is necessary before an alternative drug is used.
- For nasal carriers of MRSA—mupirocin (2%) ointment.
- All β lactam drugs should be avoided. However, 5th generation cephalosporins, such as ceftobiprole and ceftibuten have shown some activity against MRSA.

Resistance to Vancomycin (VRSA and VISA)

Erroneous and overuse of vancomycin has lead to the emergence of resistance to vancomycin. It may be of low grade resistance, known as VISA (vancomycin intermediate *S. aureus*) or high grade resistance, known as VRSA (vancomycin-resistant *S. aureus*).

- VRSA is very rare. In India, it is reported from few places such as Hyderabad, Kolkata and Lucknow. However, VISA is more frequently reported than VRSA.
- **Mechanisms:** VRSA is mediated by *Van A* gene; whereas VISA is due to increase in cell wall thickness of *S. aureus*. The *Van A* gene is believed to be acquired from a vancomycin-resistant strain of *Enterococcus faecalis* by horizontal conjugal transfer.
- Treatment of VRSA should be based on antimicrobial susceptibility report. Linezolid, telavancin, daptomycin and quinupristin /dalfopristin are effective drugs.

Control Measures

Prevention of spread of *S. aureus* infections in hospitals involves:

- **Proper hand washing:** It is the most efficient way to prevent hospital spread of *S. aureus*.
- **Screening of MRSA carriers** among hospital staff should be done when there is an outbreak. Mannitol oxacillin agar is the preferred media for this purpose.
- **Treatment of carriers** is done by use of topical mupirocin (for nasal carriers) and chlorhexidine (for skin carriers).
- **Stoppage of antibiotic misuse** in hospitals.
- **Bundling** (performing medical interventions such as the insertion of intravenous catheters, in a sequence of prescribed steps)—can reduce the rates of nosocomial infections related to such procedures.

COAGULASE-NEGATIVE STAPHYLOCOCCUS (CoNS)

Most of the CoNS are harmless commensals and less virulent than *S. aureus*; however, recently their role as pathogen is increasingly been reported.

TABLE 21.7: Tests for identification of common *Staphylococcus* species

Properties	*S. aureus*	*S. epidermidis*	*S. saprophyticus*	*S. lugdunensis*
Coagulase (tube)	+	–	–	–
Clumping factor	+	–	–	+
Heat stable thermonuclease	+	–	–	–
Phosphatase	+	+	–	–
Novobiocin	S	S	R	S
Urease	V	+	+	V
PYR	–	–	–	+
Ornithine decarboxylation	–	–	–	+

Abbreviation: PYR, pyrrolidonyl-beta-naphthylamide

Staphylococcus epidermidis

It is the most common CoNS (75–80%), isolated from clinical samples. It is present as normal flora on the skin, oropharynx and vagina; however, its pathogenic role is greatly enhanced in presence of prosthetic-devices.

- **Pathogenesis:** *S. epidermidis* involves a two-step process:
  1. **Initial adhesion to the prosthetic device:** The surface adhesins of the organism bind to host serum or tissue constituents, such as fibrinogen or fibronectin, coated on the implanted prosthetic surfaces.
  2. **Colonization:** *S. epidermidis* can produce the extracellular polysaccharide material (glycocalyx or slime) that facilitates formation of a protective **biofilm** on the device surfaces. Biofilm appears to act as a barrier, protecting bacteria from host defence mechanisms as well as from antibiotics.
- **Manifestation:** *S. epidermidis* is the most common cause of prosthetic-device related infections, such as endocarditis with insertion of valvular prosthesis and ventricular shunt infections. It is also a common cause of stitch abscess.

Staphylococcus saprophyticus

It causes urinary tract infection (UTI) in sexually active young women. This is due to expression of a 160 kDa hemagglutinin/adhesin protein that can adhere to uroepithelial cells. It can be differentiated from other staphylococci in being **resistant to novobiocin disk** (5 μg).

Staphylococcus lugdunensis and Staphylococcus schleiferi

Recently these organisms have been associated with more serious infections such as native-valve endocarditis and osteomyelitis. Their enhanced pathogenesis may be due to expression of virulence factors such as clumping factor and lipase which are usually absent in other CoNS.

Laboratory Diagnosis of CoNS

Various species of CoNS can be differentiated from each other and also from *S. aureus* by various biochemical tests (Table 21.7). Treatment same as *Staphylococcus aureus*.

EXPECTED QUESTIONS

I. Essay:

1. A 55-year-old male was admitted to the hospital with complaints of severe pain in the lateral aspect of his left calf and small amount of pus discharge from the ingrown hair. On physical examination, the local area was found to be red, warm and tender. Pus was aspirated and was subjected to Gram stain (showed gram-positive cocci in clusters), culture on blood agar (showed golden yellow pigmented beta hemolytic colonies).
   a. What is the clinical diagnosis and its causative organism?
   b. List the infections caused by this organism?
   c. List the virulence factors of this organism?
   d. Briefly discuss the laboratory diagnosis?

II. Write short notes on:

1. Toxic shock syndrome
2. Staphylococcal food poisoning
3. MRSA (Methicillin-resistant *Staphylococcus aureus)*

III. Multiple Choice Questions (MCQs):

1. Scalded skin syndrome is mediated by:
   a. Hemolysin b. Coagulase
   c. Enterotoxin d. Epidermolytic toxin

2. *Staphylococcus aureus* causes vomiting in 6–8 hours. The mechanism of action by:
   a. Stimulation of cAMP
   b. Vagal stimulation
   c. Stimulation of cGMP
   d. Acts through ganglioside GM receptor

3. A patient has prosthetic valve replacement and he develops endocarditis 8 months later. Organism responsible is?
   a. *Staphylococcus aureus*
   b. *Streptococcus viridans*
   c. *Staphylococcus epidermidis*
   d. HACEK

Answers

1. d **2.** b **3.** c

CHAPTER 22
Streptococcus, Enterococcus and Pneumococcus

Chapter Preview

- Introduction
- Streptococcus pyogenes
- Other β hemolytic streptococci
- Enterococcus species
- Viridans streptococci
- Pneumococcus

INTRODUCTION

Family Streptococcaceae are catalase negative gram-positive cocci, arranged in pairs or chains (due to single plane of division). *Streptococcus*, *Enterococcus* and pneumococcus are the important members of this family. However, according to the molecular structure, *Enterococcus* is now reclassified under separate family Enterococcaceae.

Streptococci are part of normal flora. However, some are important human pathogens, such as *Streptococcus pyogenes* causing pyogenic infections, *S. agalactiae* causing meningitis in newborn and *S. pneumoniae* causing pneumonia and meningitis in all age groups.

History

Billroth coined the term 'streptococci' (*streptos* meaning twisted or coiled), Ogston differentiated them from staphylococci and Rosenbach coined the species *S. pyogenes;* as it causes pyogenic infection.

Classification

Streptococci can be classified into—obligate anaerobes (e.g. *Peptostreptococcus* described in Chapter 26) and aerobic-facultative anaerobes group. The later can be further classified based on the hemolysis produced on 5% sheep blood agar into α, β and γ hemolytic streptococci (Fig. 22.1).

- α **hemolysis**: It is due to partial lysis of red blood cells (RBCs), producing a small (1–2 mm) zone of greenish discoloration surrounding the colonies. It is observed with viridans streptococci and pneumococci.
- β **hemolysis:** It is due to complete lysis of RBCs and zone of lysis is wide (2–4 mm). It is observed with *S. pyogenes* and other β hemolytic streptococci.
- γ **hemolysis**: It is a misnomer, there is no hemolysis surrounding the colonies, hence no change in color, e.g. *Enterococcus*.

Lancefield grouping: The β hemolytic streptococci can be further classified by **Rebecca Lancefield** (1933) based on C-carbohydrate antigen present in the cell wall into 20 serological groups named as group A–V (except I and J).

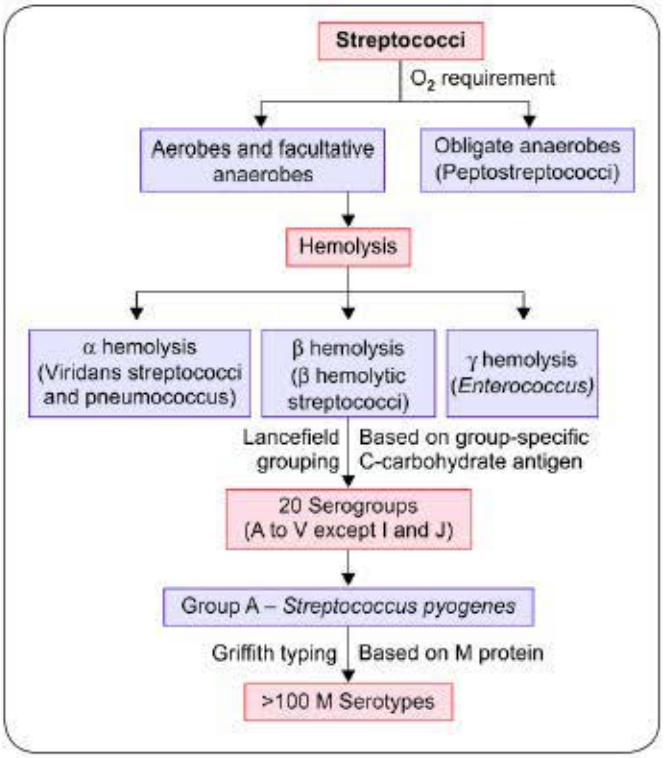

Fig. 22.1: Classification of family Streptococcaceae

Griffith typing: Majority of streptococci causing human infections belong to group A (*S. pyogenes*), which can be further classified into more than 100 serotypes based on M protein present in their cell wall.

STREPTOCOCCUS PYOGENES

S. pyogenes is the only species under Lancefield's group A *Streptococcus* (GAS). It is associated with a variety of suppurative infections and can also trigger post infectious nonsuppurative complications such as acute rheumatic fever and acute glomerulonephritis.

Virulence Factors and Pathogenicity

Virulence factors of *S. pyogenes* can be categorized into cell wall antigens, toxins and enzymes.

Cell Wall Antigens

Cell wall of *S. pyogenes* is composed of (Fig. 22.2):

- Inner **thick peptidoglycan layer**—it confers cell wall rigidity, induces inflammatory response and has thrombolytic activity.
- Middle layer of group specific **C-carbohydrate antigen**.
- Outer layer of **protein** and **lipoteichoic acid** (helps in adhesion).

Outer Protein Layer

Several protein antigens such as M, T and R proteins have been identified in the outer protein layer.

M protein: M protein is acid and heat stable, but trypsin labile. It is the principle virulence factor of group A *Streptococcus*.

- It inhibits phagocytosis (by inhibiting opsonisation via alternate complement pathway).
- It binds to fibrinogen which together bind to β2 integrins of neutrophils leading to release of inflammatory mediators that induce vascular leakage; causing streptococcal toxic shock syndrome.
- Antibody to M protein is protective in nature and promotes phagocytosis.
- The M proteins are fibrillar structures which consist of a proximal highly conservative carboxy-terminal region anchored in the streptococcal cell wall and a distal hair-like variable amino-terminal portion projected away from the cell surface.
- Based on M protein (especially, its variable amino terminal end), GAS can be typed to around 100 serotypes.
- M protein is further divided into two classes—Class I and Class II. **Antibodies to class I M protein** are responsible for pathogenesis of rheumatic fever.

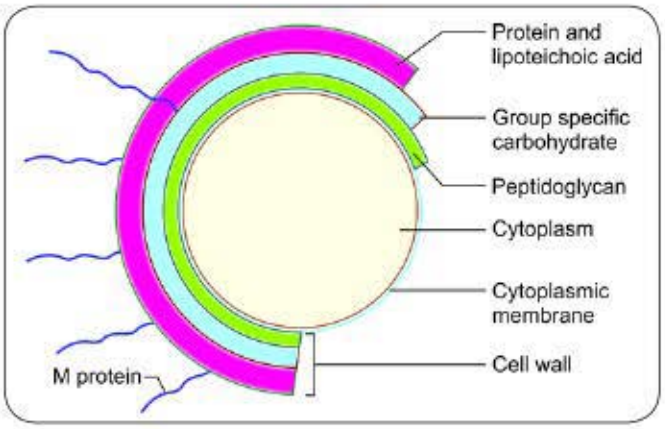

Fig. 22.2: Cell wall of *Streptococcus pyogenes*

T protein is trypsin stable but acid and heat labile. It may be specific, however many different M types possess the same T antigen.

R protein is expressed by a few strains of GAS (M types-28). Both T and R proteins are not associated with pathogenesis.

Other Cell Wall Proteins

Other cell wall proteins include:

- M associated protein
- Hair-like fimbriae (consist of M protein along with teichoic acid)—project from the cell wall and help in adhesion.
- F factor (fibronectin binding protein) helps in adhesion.

Capsule

Some strains of group A *Streptococcus* are capsulated, made up of hyaluronic acid. These strains produce mucoid colonies. Capsule is antiphagocytic, but not antigenic. It helps in group A *Streptococcus* colonization of the pharynx by binding to CD44, a hyaluronic acid-binding protein expressed on human pharyngeal epithelial cells.

Toxins

Hemolysins

β hemolytic streptococci such as group A, C and G produce two hemolysins—streptolysin-O and streptolysin-S (Table 22.1). They cause RBC membrane lysis that leads to complete β hemolysis surrounding the colonies.

Streptococcal Pyrogenic Exotoxin (SPE)

It is so named because it induces fever (pyrogenic). It is responsible for the pathogenesis of certain streptococcal infections such as scarlet fever, necrotizing fasciitis and toxic shock syndrome.

- It can be typed into three antigenic distinct subtypes SPE-A, B and C.

TABLE 22.1: Differences between streptolysin-O and streptolysin-S

Streptolysin (SL-O)	Streptolysin (SL-S)
▪ Oxygen labile (hence named as streptolysin-O) ▪ Heat labile	▪ Oxygen stable ▪ Serum soluble (hence named as streptolysin-S)
▪ Hemolysis is seen only in deep colonies (pour plate) as it is inactivated in the presence of oxygen. ▪ It is active in reduced state; but becomes inactive in oxidized state.	Causes hemolysis on the surface of blood agar plate.
It is cytotoxic for neutrophils, platelets and cardiac tissue.	It has leucocidal activity
Strongly antigenic	Not antigenic
Antistreptolysin-O antibodies (ASO) are raised in most of the streptococcal infections and are used as a standard marker for retrospective diagnosis of streptococcal infections (except in glomerulonephritis and pyoderma where ASO titer is low)	Not useful for serological diagnosis of streptococcal infections.
Streptolysin-O is structurally and functionally similar to: ▪ Tetanolysin of *Clostridium tetani* ▪ Pneumolysin of *S. pneumoniae* ▪ Thetatoxin of *Clostridium perfringens* ▪ Listeriolysin O of *Listeria* ▪ Cereolysin of *Bacillus cereus*	

- SPE-A and C are bacteriophage coded; whereas SPE-B is chromosomally mediated.
- SPE-A and C are superantigens; like staphylococcal toxin (TSST-1), they also act as T cell mitogens which induce a massive release of cytokines causing fever, shock and tissue damage.
- **Dick test:** SPE was previously called as **erythrogenic** or **scarlet fever** toxin because its intradermal injection in susceptible children produced local erythema. This test was previously used to identify the individuals susceptible to scarlet fever.

Enzymes

Streptokinase (Fibrinolysin)

It activates plasminogen to plasmin, thus breaks down the fibrin barrier around the infected site, there by facilitating the spread of infection.

- Antibodies to streptokinase can be used for retrospective diagnosis of streptococcal infection.
- Therapeutic use—being fibrinolytic, this toxin can be used in the treatment of myocardial infarction and other thromboembolic disorders.

Streptodornase (DNase)

It breaks down the DNA, thus helps in liquefying the thick pus (containing large amount of DNA derived from nuclei of necrotic cells) and may be responsible for the serous nature of streptococcal exudates.

- **Therapeutic use:** Preparation containing streptodornase and streptokinase can be used to liquefy the thick exudates in empyema cases.
- **Subtypes:** Streptodornase has four distinct subtypes DNase-A, B, C, and D of which type-B is most antigenic.
- **Diagnostic use:** Anti-DNase B antibodies can be used for retrospective diagnosis of the infection, particularly the skin infections (pyoderma) and acute glomerulonephritis where ASO titer is low.

Other Enzymes

- **Hyaluronidase (spreading factor):** It breaks down the hyaluronic acid present in tissues, thus helps in the spread of infection along the intercellular space. It is usually secreted by noncapsulated strains (such as M type 2 and 22).
- **NADase:** It acts on the coenzyme NAD (nicotinamide adenine dinucleotide). It is produced by group A, C and G. It is antigenic and leucotoxic.
- **Serum opacity factor:** It is a lipoproteinase produced by a few M serotypes of *S. pyogenes*, causes opacity when applied on agar gel containing serum.
- **SpyCEP:** It is a serine protease that inactivates interleukin 8, which is a neutrophil chemoattractant.
- **C5a peptidase:** It is a serine protease that cleaves C5a; which is also a neutrophil chemoattractant.
- Others include neuraminidase, N-acetyl glucosaminidase, esterase and phosphatase. Their pathogenic role is uncertain.

Clinical Manifestations

Group A *Streptococcus* (GAS) produces both suppurative and non-suppurative manifestations (Table 22.2).

Suppurative Complications

Respiratory Infections

Throat is the primary site of invasion by GAS. Infection occurs through respiratory droplets.

Pharyngitis (Sore Throat)

Sore throat is the most common streptococcal disease; may be localized (tonsillitis) or diffuse (pharyngitis).

- GAS is the most common cause of pharyngitis in children (20–40% of all cases).
- It is characterized by erythema and swelling of pharyngeal mucosa with purulent exudate formation.
- Younger children (< 3 years) manifest with a syndrome of fever, malaise, and lymphadenopathy without exudative pharyngitis.
- Complications occur due to spread of infection from the pharynx to deeper tissues by direct extension, hematogenous or lymphatic routes which may lead to

TABLE 22.2: Suppurative and non-suppurative manifestations of *Streptococcus pyogenes*

Suppurative	Non-suppurative
Respiratory infections ▪ Pharyngitis/sore throat ▪ Pneumonia ▪ Empyema	Acute rheumatic fever
Scarlet fever	Acute glomerulonephritis
Skin and soft tissue infections ▪ Impetigo (pyoderma) ▪ Cellulitis and erysipelas	Guttate psoriasis Reactive arthritis
Deep soft tissue infections ▪ Necrotizing fasciitis ▪ Streptococcal myositis ▪ Toxic shock syndrome	PANDAS (Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infections)
Bacteremia leading to toxic shock syndrome, osteomyelitis, meningitis, etc.	
Complications: Puerperal sepsis, otitis media, quinsy, Ludwig's angina, pneumonia (post viral), etc.	

quinsy (peritonsillar abscess), sinusitis, otitis media, meningitis, bacteremia and post viral pneumonia.

Scarlet Fever

Scarlet fever is mediated due to streptococcal toxins SPE-A, B, and C. It is characterized by pharyngitis, with:

- Characteristic rash with sandpaper feel: Rashes may be due to direct action of the circulating toxin or as a result of hypersensitivity reaction.
- Strawberry tongue (enlarged papillae on a coated tongue)
- Rash in skin folds (called Pastia's lines).

Scarlet fever has become less common now although strains producing SPE continue to be prevalent in the community. Reasons are not clear.

Skin and Soft Tissue Infections

Impetigo

It is a superficial infection of the skin, caused primarily by group A *Streptococcus* and occasionally by other streptococci or *S. aureus*.

- Risk factors include young children, warmer months, tropical climates, poor hygiene, colonization of group A *Streptococcus* and minor trauma.
- Most common sites involved are face (nose and mouth) and legs.
- Individual lesions begin as red papules, which evolve quickly into vesicles and then pustular lesions that break down and coalesce to form characteristic thin papery **honeycomb-like crusts** (Fig. 22.3A). Lesions are painless and not associated with fever.

Figs 22.3A and B: Streptococcal skin infections. **A.** Impetigo; **B.** Erysipelas on malar area of face (peau d'orange skin)

Source: A. wikipedia/Åsa Thörn, B. Public Health Image Library, Atlanta, ID# 2874/ Dr. Thomas F. Sellers, Emory University/Centers for Disease Control and Prevention (CDC) (*with permission*)

Cellulitis

It is an infection involving the skin and subcutaneous tissues.

Erysipelas: It is a form of cellulitis, characterized by a tender, bright red, swollen and indurated peau d'orange texture of involved skin (due to involvement of the superficial lymphatics) along with fever and chills. Superficial blebs or bullae may form later.

- Most common sites are malar area of the face and the lower extremities (Fig. 22.3B).
- Recurrences are common, occurs after many years, involving the same site.

Deep Soft Tissue Infections

Necrotizing Fasciitis

It is also known as **hemolytic streptococcal gangrene**. It involves the superficial and/or deep fascia invading the muscles (Fig. 22.4).

- Source of the infection may be of two types:
  1. Traumatized skin—most commonly caused by group A *Streptococcus* alone or in mixture with *S. aureus*.
  2. Gastrointestinal tract breach—It occurs due to abdominal surgery releasing the bowel flora. It is polymicrobial, involving anaerobic flora and gram-negative bacilli like *E. coli*).
- GAS is the most common cause, accounting for nearly 60% of total cases of necrotizing fasciitis. Common serotypes include M types 1 and 3 which produce streptococcal pyrogenic exotoxins.
- The onset is acute and rapid, and is marked by severe pain with minimal erythema at the site of involvement. Patients present with malaise, fever, chills, and a toxic

Fig. 22.4: Necrotizing fasciitis of hand

Source: Ignace de Hingh, Department of Surgery, Catharina Hospital Eindhoven, The Netherlands

appearance in contrast to cellulitis, where the skin appears more abnormal, but tenderness is mild.

- Later on (over several hours), disease tends to be more severe. Skin becomes dusky or mottled erythema and anesthetized (due to infarction of the cutaneous nerves induced by spreading inflammatory process) with extensive necrosis of subcutaneous tissue, fascia and muscle (Hence, GAS is also called as **flesh eating bacteria**).

TREATMENT **Nacrotizing fasciitis**

- It involves early drainage of inflammatory fluid and debridement of involved necrotic area along with antibiotics.
- The drug of choice is penicillin G plus clindamycin.

Bacteremia

Streptococcal bacteremia occurs secondary to necrotizing fasciitis, rarely with pharyngitis or cellulitis or pneumonia. It leads to variety of focal infections including endocarditis, meningitis, septic arthritis, osteomyelitis, peritonitis, visceral abscesses and toxic shock syndrome.

Toxic Shock Syndrome (TSS): Group A *Streptococcus* producing pyrogenic exotoxins may cause TSS secondary to soft tissue infection such as necrotizing fasciitis. It is characterized by shock and multisystem organ failure. In contrast to patients with staphylococcal TSS, the majority with streptococcal TSS are bacteremic.

Puerperal Sepsis

Being colonizer of female vagina, streptococci are often associated with infectious complications of childbirth, usually endometritis and associated bacteremia. Group B streptococci and anaerobic streptococci are more common to cause puerperal sepsis than GAS.

Non-suppurative Complications

Streptococcal antigens show molecular mimicry with human antigens (Table 22.3). Due to antigenic cross reactivity, antibodies produced against previous streptococcal infections cross react with human tissue to produce lesions. This accounts for a number of non-suppurative complications such as:

- Acute rheumatic fever
- Post-streptococcal glomerulonephritis (PSGN)
- Guttate psoriasis
- Reactive arthritis
- Pediatric Autoimmune Neuropsychiatric Disorders Associated with *Streptococcus pyogenes* (PANDAS)

TABLE 22.3: Antigenic cross reactivity between streptococcal antigens and the corresponding human antigens

Streptococcal antigen	Human antigen
Cell wall **M** protein (of serotypes M1, M5, M6, and M19)	Myocardium (tropomyosin and myosin)
Cell wall **C** carbohydrate	Cardiac valves
Cytoplasmic membrane	Glomerular vascular intima
Peptidoglycan	Skin antigens
Hyaluronic acid	Synovial fluid

Acute Rheumatic Fever

Acute rheumatic fever (ARF) occurs in people previously infected with streptococcal sore throat.

- **Pathogenesis:** It is unclear. It may be due to:
  - **Autoimmune theory:** Streptococcal antibodies cross react with the human tissue antigens (e.g. heart, brain and joint).
  - **Cytotoxicity theory:** Streptococcal toxins (e.g. SPE) and enzymes (e.g. SL-O) are directly cytotoxic for human cardiac cells.
- **Clinical manifestations and laboratory diagnosis:**
  - It affects heart, joints, skin and brain. The cardiac lesions include degeneration of heart valves and formation of inflammatory myocardial lesions called as **Aschoff nodules**.
  - Acute rheumatic fever is diagnosed by modified Jones criteria (Table 22.4).
  - Prognosis is variable, repeated attacks are common, hence long-term penicillin prophylaxis is indicated.
  - The ASO titer is much higher in patients with ARF than that seen in patients with group A *Streptococcus* infections without ARF.

Post-streptococcal Glomerulonephritis (PSGN)

PSGN typically occurs 2–3 weeks following either pyoderma (usually by M serotypes–49, 53-55 and 59-61) or rarely following pharyngitis (caused by M serotypes 1 and 12) (Table 22.5).

- PSGN results from lodging of antigen antibody complexes on the glomerular basement membrane,

TABLE 22.4: Revised Jones criteria for acute rheumatic fever

Criteria	Manifestations
Major manifestations	**S**ubcutaneous nodules
	Pancarditis
	Arthritis (migrating polyarthritis)
	Chorea (CNS manifestation)
	Erythema marginatum (skin lesion)
Minor manifestations	▪ Clinical: Fever, arthralgia ▪ Laboratory: Elevated ESR and C-reactive protein ▪ ECG: Prolonged P-R interval
Supporting evidence (of previous streptococcal infection)	Elevated ASO, or A positive throat culture, or Rapid antigen test for GAS, or Recent scarlet fever
Rheumatic fever is diagnosed if:	Two major manifestations or one major and two minor manifestations plus evidence of previous streptococcal infection

Abbreviations: CNS, central nervous system; ESR, erythrocyte sedimentation rate; ECG, electrocardiography; ASO, antistreptolysin O; GAS, group A *Streptococcus*

followed by complement activation. As a result urine retention and renal insufficiency occurs that leads to edema, hypertension, hematuria and proteinuria.

- Patients usually have elevated streptococcal anti-DNase B antibodies.
- PSGN usually occurs in children (5–12 years) and has a good prognosis.

Epidemiology

Humans are the natural reservoir for group A *Streptococcus*. It is highly communicable, affecting all age groups. Disease in neonates is uncommon, due to protective maternal antibody. Pharyngitis is more common in children of 3–15 years of age. Outbreaks occur commonly in areas with close contacts, such as schools and military barracks, etc.

LABORATORY DIAGNOSIS — *Streptococcus pyogenes*

- **Specimen collection and transport:** Depends on the site of the infection
- **Transport medium:** Pike's medium
- **Direct smear microscopy:** Pus cells with gram-positive cocci in short chains
- **Culture:**
  - Blood agar: Pinpoint colony with a wide zone of β-hemolysis
  - Selective media: Crystal violet blood agar and PNF media
  - Liquid media: Granular turbidity with powdery deposit
- **Culture smear microscopy:** Gram-positive cocci in short chains

LABORATORY DIAGNOSIS — *Streptococcus pyogenes*

- **Biochemical identification**
  - Catalase negative
  - Bacitracin sensitive
  - PYR test positive
- **Typing:**
  - Lancefield grouping: Shows group A *Streptococcus*
  - Typing of group A *Streptococcus*: Griffith typing and emm typing
- **Serology:**
  - ASO antibodies
  - Anti-DNase B antibodies
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Specimen Collection and Transport

It depends on the site of the lesion. Common specimens are throat swab, pus swab, exudates and blood. Specimens are transported immediately after collection or in **Pike's transport media** (composed of blood agar added with crystal violet and sodium azide).

Direct Smear Microscopy

Gram staining of pus or wound swab reveals pus cells with gram-positive cocci (0.5-1 μm) in chains (Fig. 22.5). However, direct microscopy is not much useful when *S. pyogenes* is a part of normal flora in the sample (e.g. throat swab).

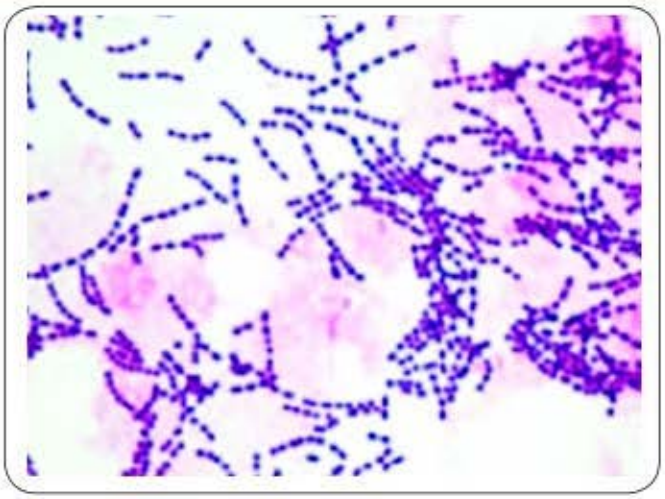

Fig. 22.5: Streptococci in Gram stained smear of pus

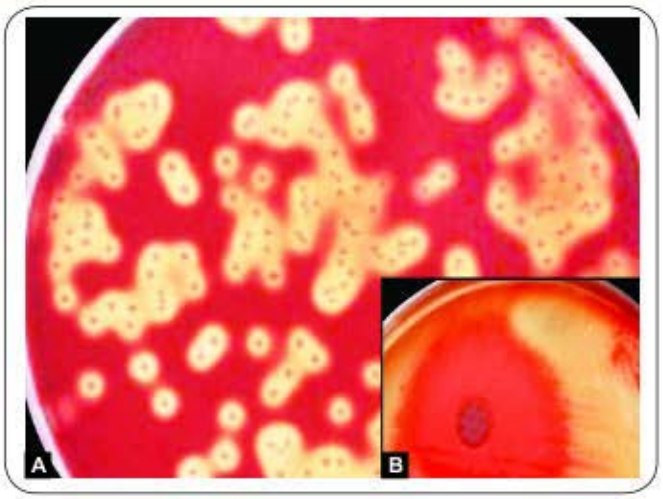


Figs 22.6A and B: *Streptococcus pyogenes*. **A.** Growth on blood agar with wide zone of beta hemolysis around the pin point colonies; **B.** Bacitracin sensitive

Culture

The specimens are inoculated onto various media and incubated overnight at 37°C aerobically in presence of 5–10% CO_2. *S. pyogenes* is fastidious, does not grow on MacConkey agar and basal media like nutrient agar or peptone water broth. It grows only in media enriched with blood, serum or carbohydrate.

- **Blood agar:** Colonies are small 0.5–1 mm, pinpoint, circular, semitransparent, low convex with a wide zone of β hemolysis (Fig. 22.6A). Stabbing of the colonies may enhance streptolysin-O induced hemolysis. Colonies of capsulated strains are mucoid.
- **Liquid media** can be used such as glucose or serum broth or brain heart infusion broth. Growth appears as granular turbidity with powdery deposit.
- **Selective media** used are as follows:
  - **Crystal violet blood agar:** Crystal violet (0.1%) inhibits the growth of staphylococci and other bacteria.
  - **PNF media:** This medium is composed of horse blood agar with polymyxin B, neomycin and fusidic acid.

Culture Smear Microscopy

Gram stained smear from the colonies show gram-positive spherical cocci (0.5–1 μm), arranged in chains. Hanging drop reveals non-motile cocci.

Biochemical Tests for Identification

- **Catalase test:** Streptococci are catalase negative. This test differentiates them from staphylococci which are catalase positive.
- **Bacitracin sensitivity testing:** Group A *Streptococcus* is sensitive to bacitracin 0.04 U disk (any zone of inhibition around the disk is considered as positive test), while most of other β hemolytic streptococci are resistant. Hence, it can be used as a rapid diagnostic test for GAS (Fig. 22.6B).

Various tests to differentiate GAS from group B β-hemolytic streptococci are tabulated in Table 22.6.

TABLE 22.6: Differences between *Streptococcus pyogenes* and *S. agalactiae*

Characters	*S. pyogenes*	*S. agalactiae*
Lancefield grouping	Group A	Group B
Bacitracin sensitivity test	Sensitive	Resistant
PYR test	Positive	Negative
Hippurate hydrolysis test	Negative	Positive
CAMP test	Negative	Positive
β hemolytic colonies	0.5–1 mm, pin point	Mucoid, larger (2 mm)

Lancefield Grouping

The biochemical identification of Group A *Streptococcus* can be further confirmed by Lancefield grouping. Lancefield grouping is extremely useful in epidemiological studies. Here, the β hemolytic streptococci are grouped serologically based on C-carbohydrate antigen. Test involves extraction of C-carbohydrate antigen followed by testing with group specific antisera.

- C-carbohydrate antigen extraction is done- either by hydrochloric acid (Lancefield's acid extraction), or by formamide (Fuller's method) or by autoclaving (Rantz and Randall method) or by an enzyme produced by *Streptomyces albus* (Maxted's method).

- Extracted antigen is tested with commercially available group specific antisera by:
  - Ring precipitation test (white disc of precipitate is formed at the interface of antigen extract and homologous antisera in a capillary tube).
  - Other methods include latex agglutination (most commonly used), gel diffusion, fluorescent testing and ELISA.

Typing of Group A Streptococci

Group A *Streptococcus* can further be typed based on two methods; phenotypic method, i.e. serological (Griffith typing) and genotypic method (*emm* typing).

- **Griffith typing:** Based on M protein (especially, its variable amino terminal end), GAS can be typed into around 100 serotypes. M protein can be extracted by Lancefield's acid extraction method and typing is done with type specific antisera.
- ***emm* typing:** A few strains of GAS are untypable serologically. Hence, gene coding of M protein (*emm* gene) is widely used for typing. This method is almost replacing the conventional serological typing. More than 124 *emm* genotypes of GAS have been identified so far.

Serology

In rheumatic fever and post streptococcal glomerulonephritis (PSGN), a retrospective diagnosis of streptococcal infection may be established by detecting antibodies in patient's serum.

- **ASO (Anti-streptolysin O) antibodies:** ASO titer is elevated (>200 IU/ml) in most of the streptococcal infections except pyoderma and PSGN. Previously neutralization test was followed for ASO detection, however, currently it is detected by latex agglutination test.
- **Anti-DNase-B antibodies**: Titer more than 300–350 units/mL is diagnostic of PSGN and pyoderma.
- Other antibodies elevated are antihyaluronidase antibodies and anti-streptokinase antibodies.

Antimicrobial Susceptibility Test

Antimicrobial susceptibility test is carried out on blood agar by disk diffusion test.

TREATMENT — ***Streptococcus pyogenes***

Penicillin is the drug of choice for pharyngeal infections as well as for suppurative complications. Resistance to penicillin is not reported yet.

- However, failure to penicillin treatment may occur due to—(1) non compliance, if discontinued before 10 days of full course of oral penicillin V, (2) β lactamases produced by normal throat flora such as *Moraxella*.
- Macrolide, such as erythromycin is given to patients allergic to penicillin. However, resistance to macrolides is common.
- Treatment of streptococcal infections is outlined in Table 22.7.

TABLE 22.7: Treatment of streptococcal infection

Conditions	Treatment recommended
Pharyngitis	Benzathine penicillin G, IM single dose; or Oral penicillin V for 10 days
Erysipelas/cellulitis	Mild: Procaine penicillin Severe: Penicillin G
Necrotizing fasciitis	Surgical debridement (most crucial) + Penicillin G + Clindamycin
Pneumonia and empyema	Penicillin G + drainage of empyema
Streptococcal toxic shock syndrome	Penicillin G + Clindamycin + immunoglobulin (to streptococcal pyrogenic exotoxin)
Rheumatic fever	Benzathine penicillin G, IM single dose; or Oral Penicillin V for 10 days Long-term maintenance therapy- with penicillin G monthly for duration: ▪ 5 years or until 21 years of age (without carditis) ▪ 10 years (with carditis) ▪ up to 40 years of age/lifelong (with residual heart disease)
Post streptococcal glomerulonephritis	Benzathine penicillin G, IM single dose; or oral penicillin V for 10 days
Treatment of asymptomatic carriers	
Pharyngeal carriers	Penicillin V + rifampicin
Rectal carriers	Vancomycin + rifampicin

Abbreviation: IM, intramuscular

Prophylaxis

Long term maintenance therapy with penicillin (alternative-sulfadiazine or erythromycin in penicillin allergy) is required for children who develop early signs of rheumatic fever. This prevents streptococcal reinfection and further damage to heart.

OTHER β HEMOLYTIC STREPTOCOCCI

Group B Streptococci (S. agalactiae)

Pathogenesis and Clinical Manifestations

Approximately 30% of women are vaginal or rectal carriers of group B *Streptococcus* (GBS). Hence, the GBS infection is common in neonates and in pregnancy.

- Group B *Streptococcus* has been recognized as a major cause of neonatal sepsis and meningitis. Neonatal sepsis can be of two types—early onset and late onset type (Table 22.8).
- Infections in pregnancy can lead to peripartum fever in women.
- Infections in adults generally involve elderly or people with underlying chronic illness, such as diabetes mellitus or malignancy. Common infections are

TABLE 22.8: Early and late onset group B *Streptococcus* disease in neonates

Characteristics	Early-onset disease	Late-onset disease
Age of onset	0–6 days of birth	7–90 days of birth
Increased risk following obstetric complications	Prematurity and prolonged labor	Not associated
Mode of transmission to the baby	During or before birth from the colonized maternal genital tract	Contact with a colonized mother and nursing personnel
Common clinical manifestations	Pneumonia and/or respiratory distress syndrome followed by meningitis	Bacteremia and meningitis (most common)
Common serotypes	Ia, III, V, II, Ib	Type III (most common)
Case fatality rate	4.7%	2.8%

cellulitis and soft tissue infections (including infected diabetic skin ulcers), urinary tract infection, pneumonia and endocarditis.

- Group B *Streptococcus* has a capsular polysaccharide which can be typed into nine serotypes.

Laboratory Diagnosis

It is catalase negative like all streptococci, but exhibits the following biochemical properties that differentiate it from group A *Streptococcus*.

- **CAMP positive:** CAMP factor (named after the discoverers: Christie, Atkins-Munch-Petersen) is a phospholipase produced by GBS that causes synergistic hemolysis with β hemolysin produced by *S. aureus*. When GBS is streaked on blood agar plate perpendicular to *S. aureus*, an enhanced arrow head shaped hemolysis is produced at their junction, pointing towards GBS streak line (Fig. 22.7).
- Hippurate hydrolysis test positive
- Bacitracin resistant
- PYR (Pyrrolidonyl-beta-naphthylamide) is negative

Fig. 22.7: *Streptococcus agalactiae* showing positive CAMP test

- Orange pigment production—enhanced in Islam's medium.
- β hemolytic colonies are mucoid and slightly larger (2 mm).

TREATMENT **Group B Streptococci**

Penicillin is the drug of choice for all GBS infections. GBS is less sensitive to penicillin than GAS, hence a higher dose of penicillin is recommended.

Prevention

Screening for anogenital colonization of GBS is recommended at 35–37 weeks of pregnancy and prophylactic ampicillin or penicillin is given to carrier mothers during delivery to reduce the risk of infection to the newborn.

Group C Streptococci

Group C streptococci commonly cause infection in animals and comprise of four species—*S. equi, S. equisimilis, S. dysgalactiae, S. zooepidermicus*. Human infection is rare.

- *S. equisimilis* can cause pharyngitis especially epidemic food-borne pharyngitis after ingestion of contaminated animal products (milk).
  Other deep infections include skin and soft tissue infections, osteomyelitis, pneumonitis, infective endocarditis, bacteremia, meningitis, epiglottitis, pericarditis, urinary tract infections and puerperal sepsis.
- *S. equisimilis* is a common source of streptokinase, which is used for thrombolytic therapy.

Group F Streptococci

They are also called **minute streptococci**. They grow poorly on blood agar, occasionally cause suppurative infection.

Streptococcus MG is an α hemolytic strain belonging to this group. Demonstration of antibodies to *Streptococcus* MG in the patient's sera has been used for diagnosis of primary atypical pneumonia (caused by *Mycoplasma pneumoniae*).

Group G Streptococci

They are throat commensals, occasionally cause puerperal sepsis, neonatal infection, skin and soft tissue infections, tonsillitis, and endocarditis.

Group D Streptococci

Group D streptococci comprise of enterococci (fecal streptococci, described below) and non-enterococci (*S. bovis* and *S. equinus*). They possess the common group D lipoteichoic acid antigen.

ENTEROCOCCUS

Enterococci were initially grouped under group D *Streptococcus*, but later, it has been reclassified as a separate

TABLE 22.9: Comparing enterococci and Group D streptococci

Features	Enterococci	Group D streptococci
Group specific D Ag	Present	Present
Bile aesculin hydrolysis	Positive	Positive
In presence of ▪ 6.5% NaCl ▪ pH 9.6 ▪ at 45°C ▪ at 10°C	Grows	Does not grow
PYR test	Positive	Positive
Drug resistance	Marked	Uncommon
Existence as normal intestinal flora	More common	Less common
Pathogenicity	Marked	Less

PYR, Pyrrolidonyl-beta-naphthylamide

genus *Enterococcus*. Based on the molecular structure; it is now placed under a new family; Enterococcaceae.

Both enterococci and non-enterococcal group D streptococci give a positive **bile aesculin hydrolysis test** (they grow in the presence of 40% bile and hydrolyse aesculin to aesculetin that combines with ferric chloride to produce black colored complex). However, they differ in many other properties (Table 22.9).

Virulence Factors

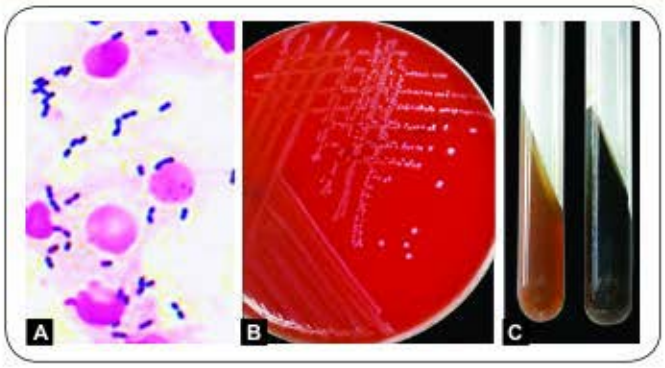
Enterococci are part of normal flora of human intestine, biliary tract and to lesser extent vagina and male urethra. At the same time, enterococci are also becoming increasingly important agents of human disease especially in hospitals mainly because of their resistance to antibiotics. *E. faecalis* is the most common species found in clinical specimens, whereas *E. faecium* is more drug resistant than *E. faecalis*. They exhibit a number of virulence factors such as:

- **Cytolysin/hemolysin:** They lyse the sheep and human RBCs.
- **Aggregation substances or pheromones:** They help in clumping of adjacent cells to facilitate plasmid exchange (transfers drug resistance).
- **Extracellular surface protein (ESP):** It helps in adhesion to bladder mucosa.
- **Common group D lipoteichoic acid antigen:** It induces cytokine release such as tumor necrosis factor α (TNFα).
- **Coccolysin:** It inactivates endothelin, a vasoactive peptide.

Clinical Manifestations

Enterococci produce various infections such as:

- Urinary tract infections (cystitis, urethritis, pyelonephritis and prostatitis)
- Bacteremia and mitral valve endocarditis (in intravenous drug abusers)
- Intra-abdominal, pelvic and soft tissue infections
- Late-onset neonatal sepsis and meningitis
- Infection on burn surface



Figs 22.8A to C: *Enterococcus*. **A.** Gram-positive oval cocci in pairs; **B.** translucent non-hemolytic colonies on blood agar; **C.** Bile aesculin agar (left—negative, right—positive result, black color due to aesculin hydrolysis)

Laboratory Diagnosis

Enterococci show the following characteristics that help in their identification:

- They are gram-positive oval cocci (Fig. 22.8A) arranged in pairs; cocci in a pair are arranged at an angle to each other (**spectacle eyed** appearance).
- Non-motile cocci (except *E. gallinarum* and *E. casseliflavus*).
- **Blood agar:** It produces non-hemolytic (Fig. 22.8B), translucent colonies (rarely produces α or β hemolysis).
- **MacConkey agar:** It produces minute magenta pink colonies.
- **Nutrient agar:** It grows poorly.
- Bile aesculin hydrolysis test is positive (Fig. 22.8C).
- PYR (Pyrrolidonyl-beta-naphthylamide) test is positive.
- They can grow in presence of extremes of conditions such as—6.5% NaCl, 40% bile, pH 9.6, 45°C and 10°C.
- **Heat tolerance test:** They are relatively heat resistant, can survive 60°C for 30 minutes.
- **Groups:** Enterococci can be divided into five groups—group I to V based on mannitol fermentation and arginine hydrolysis. *E. faecalis* and *E. faecium* belong to group II, which can be further differentiated by several biochemical properties (Table 22.10).

TABLE 22.10: Differentiating features between *Enterococcus faecalis* and *E. faecium*

Features	*E. faecalis*	*E. faecium*
Arabinose	Not fermented	Fermented
Sorbitol	Fermented	Not fermented
Pyruvate	Fermented	Not fermented

TREATMENT ***Enterococcus***

Most strains of enterococci are resistant to penicillins, aminoglycosides and sulfonamides. They show intrinsic resistance to cephalosporins and cotrimoxazole.

- Resistance is overcome by combination therapy with penicillin (or ampicillin) and aminoglycoside (due to synergistic effect) and this remains the standard therapy for life-threatening enterococcal infections; however in UTI, monotherapy with ampicillin or nitrofurantoin is sufficient. Resistance to this combination therapy may also develop.
- Vancomycin is usually indicated in resistant cases but resistance to vancomycin has also been reported.

Vancomycin Resistant Enterococci (VRE)

Vancomycin resistance in enterococci has been increasingly reported now a days.

- VRE is mediated by *Van* gene, which alters the target site for vancomycin present in the cell wall; i.e. D-alanyl-D-alanine side chain of peptidoglycan layer (which is the usual target site for vancomycin), is altered to D-alanyl-D-serine or D-alanyl-D-lactate. This altered side chains have less affinity for binding to vancomycin.
- ***Van* gene has 5 genotypes**: *Van* A to *Van* E.
  - Strains with *Van* A gene show high level resistance to both glycopeptides vancomycin and teicoplanin.
  - Strains with *Van* B gene show low level resistance to vancomycin, but sensitive to teicoplanin.
  - *E. gallinarum* and *E. casseliflavus* possess *Van* C genes and they show intrinsic resistance to both the glycopeptides.

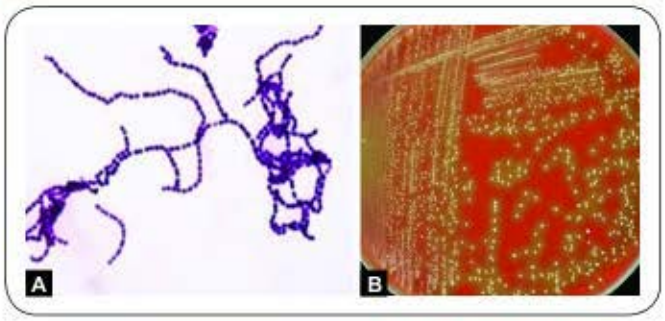
VIRIDANS STREPTOCOCCI

Viridans streptococci are commensals of mouth and upper respiratory tract. Ordinarily, they are nonpathogenic, however occasionally cause disease such as:

- **Dental caries**: It is mainly caused by *S. mutans* which breaks down dietary sucrose to acid and dextrans. Acid damages the dentine, while adhesive dextran binds together with food debris, mucus, epithelial cells and bacteria to produce **dental plaques**.
- **Subacute bacterial endocarditis (SABE):** Viridans streptococci are the most common cause of SABE. The commensal viridans streptococci (*S. sanguis*) in the oral cavity can enter blood to cause transient bacteremia while chewing, tooth brushing and dental procedures that can account for the predilection of these organisms to cause endocarditis.
- ***S. milleri* group** (includes *S. intermedius, S. anginosus,* and *S. constellatus)*: Produce suppurative infections particularly abscesses of brain and abdominal viscera.

Laboratory Diagnosis

- On Gram stain, they appear as long chains of gram-positive cocci (Figs 22.9A and B).



Figs 22.9A and B: Viridans streptococci. **A.** Gram-positive cocci in long chains; **B.** α hemolytic colonies on blood agar

TABLE 22.11: Differences between *Streptococcus pneumoniae* and Viridans streptococci

Features	*S. pneumoniae*	Viridans streptococci
Arrangement	Gram-positive cocci in pairs (Fig. 22.10)	Gram-positive cocci in long chains
Morphology	Lanceolate or flame shaped	Round/oval
Capsule	Present	Absent
On blood agar	Draughtsman or carom coin colony	Convex shaped colony
Liquid medium	Uniform turbidity	Granular turbidity
Bile solubility	Soluble in bile	Insoluble in bile
Inulin fermentation	Fermenter	Non fermenter
Optochin	Sensitive	Resistant
Mice pathogenicity	Pathogenic	Non-pathogenic

- They produce minute α or green hemolytic (rarely non-hemolytic) colonies on blood agar (*"viridis"* means green).
- They can be differentiated from *S. pneumoniae* (which is also α hemolytic) by a number of tests (Table 22.11).

TREATMENT **Viridans streptococci**

They are usually sensitive to penicillin except in neutropenic patients with bacteremia, where vancomycin is given.

PNEUMOCOCCUS

Streptococcus pneumoniae (commonly referred to as pneumococcus) is the leading cause of lobar pneumonia, otitis media in children and meningitis in all ages. They are α hemolytic and may present as commensals in human upper respiratory tract. They differ from α hemolytic viridans streptococci in many ways such as their shape (lanceolate-shaped diplococci), bile solubility, optochin sensitivity and presence of a polysaccharide capsule (Table 22.11).

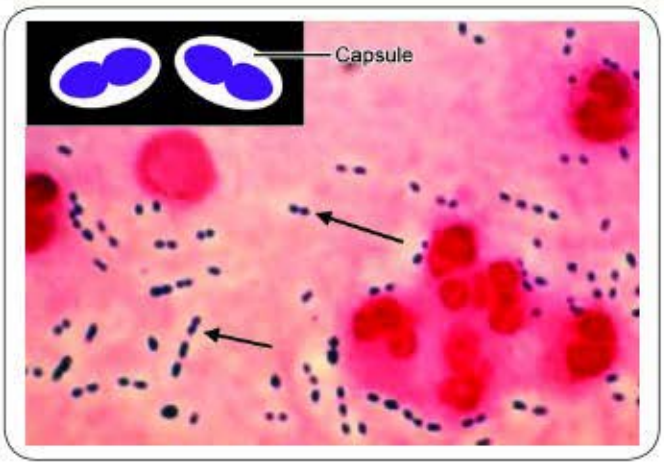


Fig. 22.10: Pneumococci in Gram stained smear of sputum [lanceolate shaped gram-positive cocci in pair surrounded by clear halo (capsule)] (arrows showing)

Virulence Factors and Pathogenesis

S. pneumoniae possesses a number of virulence factors such as:

- **Capsular polysaccharide:** It is the principal virulence factor, protects the cocci from phagocytosis. It is type specific (>90 capsular serotypes are recognized). Being soluble, it diffuses into culture media, tissue and exudates, hence also called **soluble specific substance**.
- **C carbohydrate antigen** (C-polysaccharide or C-substance): It is species specific, made up of ribitol, teichoic acid linked to fragments of peptidoglycan. In sera of patients with acute inflammation, a beta globulin appears (synthesized by liver) that precipitates with pneumococcal C-antigen, hence it is named as **C-reactive protein (CRP)**. However, it is not an antibody to C-antigen. CRP is a non-specific acute phase reactant protein, can be raised in many inflammatory conditions (infective as well as noninfective conditions, such as malignancies) and disappears once the inflammation subsides.
- **Pneumolysin**: It is a membrane damaging toxin, which inhibits neutrophil chemotaxis and phagocytosis, similar to streptolysin-O.
- **Autolysin:** It is an amidase enzyme that cleaves its own peptidoglycan leading to autolysis of cells. The activity is enhanced in presence of bile salts and other surface active agents. This property is responsible for characteristic bile solubility and draughtsman appearance of pneumococcal colonies. Release of cell wall fragments lead to a self perpetuating inflammatory response that contributes to the pathogenesis.
- **Other virulence factors:**
  - **Pneumococcal surface protein A (PspA):** It prevents complement activation. It shows some similarities to the M protein of *S. pyogenes*.
  - **IgA protease:** It cleaves IgA, present in the respiratory mucosa, thus facilitates entry.
  - **Pneumococcal surface protein C (PspC):** It is also known as *choline-binding protein A* (CbpA). It binds to factor H and accelerates the breakdown of C3 complements.
  - **Adhesins:** These include sialidase (neuraminidase) and pneumococcal surface adhesin A (PsaA).

Clinical Manifestations

Pneumococci colonize the human nasopharynx at an early age. From the nasopharynx, the bacteria spread either via the bloodstream to distant sites (e.g. brain, joint, bones and peritoneal cavity) or spread locally to cause otitis media or pneumonia.

Various manifestations include:

- **Lobar pneumonia:** *S. pneumoniae* is the most common cause of lobar (alveolar) pneumonia. Though starts as noninvasive illness due to contiguous spread from the nasopharynx, it soon becomes bacteremic and invasive. Patients present with productive purulent cough, fever and chest pain. Important signs are dullness on percussion due to consolidation and crackles on auscultation.
- **Empyema and parapneumonic effusion** may occur as complications of pneumococcal pneumonia.
- **Pyogenic meningitis:** *S. pneumoniae* is the leading cause of meningitis in all ages (except in neonates).
- **Other invasive manifestations:** *S. pneumoniae* can cause osteomyelitis, septic arthritis, endocarditis, pericarditis, primary peritonitis, rarely, brain abscess and hemolytic-uremic syndrome.
- **Non invasive manifestations** can occur such as otitis media and sinusitis where *S. pneumoniae* is the most common cause.

Epidemiology

- **Source** of infection is human upper respiratory tract of carriers (less often patients).
- **Carrier rate:** More than 90% of children of 6 months to 5 years of age harbor *S. pneumoniae* in the nasopharynx.
- **Mode of transmission** is by inhalation of contaminated droplet nuclei.
- Infection usually leads to colonization and carrier state. Disease results only when the host resistance is lowered due to presence of associated risk factors.

Risk Factors

- **Children (<2 years):** Children are at higher risk to develop pneumococcal infection because of their inability to produce adequate antibodies against the capsular antigen; owing to the immature immune system.

- **Splenectomy, sickle cell disease and other hemoglobinopathies:** As spleen is the site of destruction of capsulated bacteria, the conditions where the opsonisation and clearance of circulating bacteria by the spleen is hampered, there is increased risk of pneumococcal infection.
- **Underlying comorbid diseases:** Such as chronic lung, heart, kidney and liver disease, cochlear implants, diabetes mellitus and immunosuppression (e.g. HIV).
- Underlying viral upper respiratory tract infections (e.g. influenza).
- **Nature of infecting serotypes:**
  - **In children:** Serotypes 4, 6B, 9V, 14, 18C, 19F, and 23F are common
  - **In adults:** Serotypes 1–8 are common
  - **Virulent serotypes:** Serotype 3 followed by 7 are more virulent strains than others.

LABORATORY DIAGNOSIS — *Streptococcus pneumoniae*

- **Specimen collection:** Sputum, CSF, pleural fluid
- **Direct smear microscopy:** Reveals pus cells and lanceolate shaped gram-positive cocci in pairs, surrounded by a clear halo (due to capsule)
- **Capsular antigen detection in CSF:** By latex agglutination
- **Culture**
  - Blood agar: It shows draughtsman or carrom coin appearance to colonies
  - Chocolate agar: It produces greenish discoloration (bleaching effect)
  - In liquid media: It shows uniform turbidity
- **Culture smear:** Reveals lanceolate shaped gram-positive cocci in pairs.
- **Biochemical identification**
  - Bile soluble
  - Optochin sensitive
  - Inulin fermented
- **Serotyping:** By Quellung reaction or latex agglutination test
- **Mouse pathogenicity**
- **Molecular methods:** Such as multiplex PCR
- **Non-specific findings:** ↑ acute phase reactant proteins, e.g. C reactive protein, procalcitonin
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Specimen Collection

Depending on the site of infection, specimens such as sputum, cerebrospinal fluid (CSF), pleural fluid and other sterile body fluids are collected. Blood culture is useful for invasive infection.

Direct Smear Microscopy and Antigen Detection

Direct microscopy of smears made from sputum, pus or CSF show numerous pus cells and **lanceolate or flame** shaped gram positive cocci (1 µm) in pairs, surrounded by a clear halo (due to capsule). Direct microscopy is extremely useful especially for meningitis as empirical treatment (antibiotics) can be started early (Fig. 22.10). Capsules can be better demonstrated by India ink stain of CSF.

Detection of capsular antigens in CSF is more sensitive than microscopy. It is done by latex agglutination test using latex beads coated with anti-capsular antibodies.

Culture

S. pneumoniae is fastidious, does not grow in basal media like nutrient agar or nutrient broth. Specimens are inoculated in enriched media, such as blood agar, and chocolate agar and incubated for 24 hours at 37°C in presence of 5–10% of CO_2.

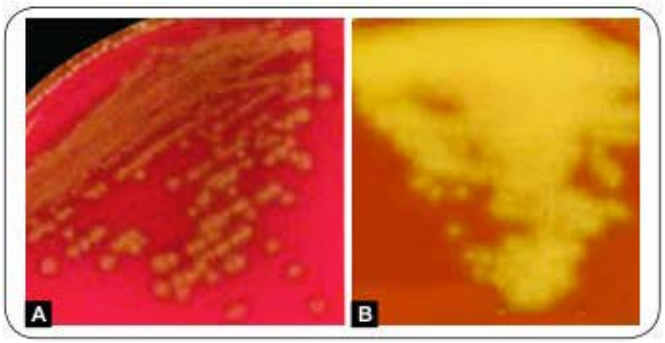
- **Blood agar:** After 18 hours of incubation, colonies on blood agar are small (0.5–1 mm), dome shaped, glistening surrounded by green discoloration due to α hemolysis. On further incubation, colonies become flat with raised edge and central depression or umbonation due to autolysis of center of the colonies by autolysin enzyme. Colonies appear as concentric rings when viewed from above **(draughtsman shaped or carom coin appearance)** (Fig. 22.11A).
- **Chocolate agar:** It produces greenish discoloration (described as bleaching effect) (Fig. 22.11B).
- In liquid media such as glucose broth or BHI broth (brain heart infusion broth): It produces uniform turbidity that readily undergoes autolysis.

Culture Smear

Gram stained smear of the colonies reveals lanceolate or flame shaped gram-positive cocci (1 µm) in pairs. Motility testing by hanging drop shows non motile cocci.

Biochemical Identification

Pneumococci are catalase negative and can be differentiated from viridans streptococci (which are also α hemolytic, found as oral commensals in sputum specimens) in various ways (Table 22.11).

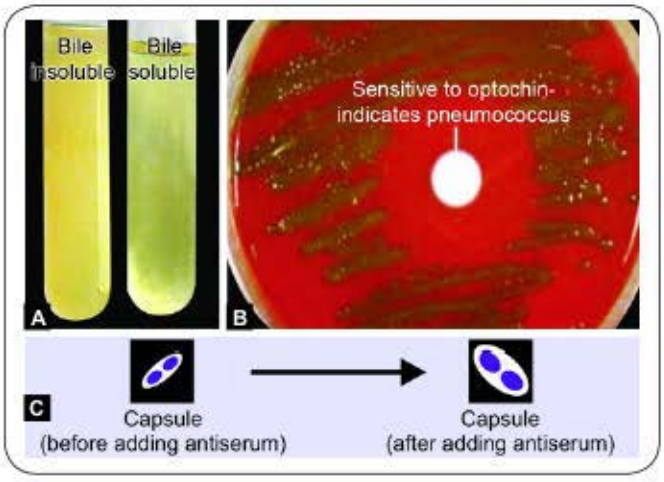


Figs 22.11A and B: Colonies of pneumococcus. **A.** α hemolytic draughtsman shaped colonies on blood agar; **B.** Bleaching effect on chocolate agar

- **Bile solubility:** Pnemococci are soluble in bile due to their enhanced autolytic activity in presence of bile. Viridans streptococci are insoluble in bile. Bile solubility can be demonstrated by:
  - **Plate method** (drop of 2% sodium deoxycholate is added to pneumococcal colonies on blood agar, incubated at 37°C, colonies disappear leaving behind a zone of green hemolysis within 30 minutes).
  - **Tube method** (0.5 mL of 10% sodium deoxycholate is added to BHI broth with pneumococcal growth, incubated at 37°C for 3 hours, checking hourly whether the medium becomes clear) (Fig. 22.12A).
- **Optochin sensitivity:** Pneumococci are sensitive to optochin disk (5 µg of ethyl hydrocuprein) and produce wider zone of inhibition (14 mm or more) (Fig. 22.12B). Viridans streptococci are resistant to optochin.
- **Inulin fermentation:** Pneumococci can ferment inulin to form acid, but not viridans streptococci. Fermentation test should be carried out in Hiss's serum sugar medium.

Typing of S. Pneumoniae

- **Quellung reaction**: Capsular swelling can be demonstrated by adding type-specific antiserum (omni-serum) raised in rabbit, along with dye such as methylene blue to pneumococcal colonies on a slide and viewed under microscope. In presence of homologous antiserum, capsule becomes swollen, sharply delineated and refractile. Quellung test was routinely done in the past, at bedside directly from sputum samples from acute pneumonia cases (Fig. 22.12C).
- Currently, serotyping is done by more preferred methods such as latex agglutination and coagglutination test using type specific antisera.



Figs 22.12A to C: A. Bile solubility test (left-Viridans streptococci, not soluble in bile; right-pneumococcus, soluble in bile); **B.** Optochin sensitivity; **C.** Quellung reaction

Mouse Pathogenicity

In samples having fewer organisms where culture is negative, isolation can be done by intraperitoneal inoculation into mice, which die in 1–2 days and pneumococci may be demonstrated in the heart blood and peritoneal exudates of the animal.

Molecular Methods

Multiplex PCR can be done to detect genes of *S. pneumoniae*. This is more useful in CSF samples where organism load is scanty.

Nonspecific Findings

- Elevated acute phase reactant proteins such as C reactive protein, procalcitonin
- Leukocytosis
- Chest X-ray shows infiltrates and lobar consolidation. (In children-distinctly spherical consolidation seen in upper part of the lower lobe called round pneumonia).

Antimicrobial Susceptibility Test

It is done for institution of proper antibiotic treatment.

TREATMENT	*Streptococcus pneumoniae*
Penicillin G remains the drug of choice, with daily doses ranging from 50,000 U/kg for minor infections upto 300,000 U/kg for meningitis. Cephalosporins, such as ceftriaxone can be given alternatively. Oral amoxicillin is recommended for children with acute otitis media.	

Drug Resistance in Pneumococcus

Penicillin resistance in pneumococci has been reported increasingly now a days. This resistance is due to alteration of penicillin-binding protein (PBP) to PBP2b. This altered PBP2b has low affinity for β lactam drugs. The gene coding for altered PBP is acquired by transformation and horizontal transfer of DNA from related streptococcal species.

Macrolides are given as alternative for penicillin-resistant pneumococci or for patients allergic to penicillin.

Multidrug resistant (MDR) *S. pneumoniae* (resistant to penicillin, tetracycline, erythromycin, sulphonamides and clindamycin) have increased during the past several decades. Some serotypes can undergo **capsule switching** (change from one serotype to another), which may be associated with development of antibiotic resistance.

Prevention and Vaccination

Measures to prevent pneumococcal disease include vaccination, treatment of underlying diseases that increase the risk of pneumococcal disease, and prevention of antibiotic overuse.

Capsular Polysaccharide Vaccines

Two types of pneumococcal vaccines are available.

23-valent Pneumococcal Polysaccharide Vaccine (PPV23)

PPV23 contains capsular polysaccharide of 23 serotypes of pneumococcus. It gives protection for about 5 years.

- **Indication:** It is recommended for people with:
  - Asplenia or splenic dysfunction
  - Sickle cell disease or celiac disease
  - Chronic lung, heart, kidney and liver disease
  - Immunocompromised patients (including HIV)
  - Diabetes mellitus
  - Cochlear implants
  - CSF leaks
  - Age above 65 years
- **Contraindication to PPV-23 includes:**
  - Malignancies
  - Pregnancy
  - Children of less than 3 years—as capsular antigens are examples of T independent antigen, they are poorly immunogenic to children of less than 3 years. Hence, PPV 23 is not useful to children <3 years age.

7-valent Polysaccharide Conjugate Vaccine (PCV-7)

It consists of capsular polysaccharide of 7 serotypes of pneumococcus added to a protein conjugate (such as CRM197 protein of *Corynebacterium diphtheriae*). It mainly includes the childhood serotypes (such as 6B, 9V, 14, 19F, 23F, and 18C).

- When a protein conjugate is added, it increases the immunogenicity of capsular antigen (acts as adjuvant), hence, it can be given to children of less than 3 years.
- PCV-7 is recommended for all infants in a schedule of 4 doses administered at 2, 4, 6, and 12–15 months of age.
- As resistance to antibiotics is most often noted in pneumococcal serotypes 6, 9, 14, 19, and 23; hence use of PCV-7 has shown to decrease pneumococcal resistance.

EXPECTED QUESTIONS

I. Essays:

1. Chinu, a 3-year-old girl from Mangalore has developed sore throat, difficulty in swallowing. On examination, the pharyngeal mucosa was found to be inflamed. A clinical diagnosis of pharyngitis was made. The culture of the throat swab revealed beta hemolytic pin point colonies.
   a. What is the most likely etiologic agent?
   b. Describe the virulence factors and the other clinical manifestations produced by the etiological agent?
   c. Briefly discuss the laboratory diagnosis of the infections caused by this organism?
2. Alisha, A 4-year-old girl from Bhubaneswar was brought to the emergency room by her parents due to an acute onset of fever, neck rigidity and altered sensorium for past 2 days. Physical examination showed that when her neck was passively flexed, her legs also flexed (positive Brudzinski's sign). Direct examination of the CSF showed gram-positive, lanceolate-shaped diplococci surrounded by a halo.
   a. What is your clinical diagnosis of this condition and the most likely etiologic agent?
   b. How will you confirm the etiological agent in the laboratory?
   c. Describe the virulence factors and pathogenesis of the etiological agent?

II. Write short notes on:

1. Non-suppurative sequelae of *S. pyogenes* infection
2. Group B *Streptococcus*
3. Pneumococcal vaccines
4. Vancomycin resistant Enterococci

III. Multiple Choice Questions (MCQs):

1. Serotyping of *Streptococcus pyogenes* is based on which of the following protein?
a. M protein b. T protein
c. R protein d. Carbohydrate antigen

2. *Streptococcus pyogenes* can be differentiated from *Streptococcus agalactiae* by:
a. Optochin sensitivity b. Bacitracin sensitivity
c. Polymyxin sensitivity d. Novobiocin sensitivity

3. CAMP test is useful in identification of:
a. *S. pyogenes* b. *S. agalactiae*
c. Viridans streptococci d. *S. pneumoniae*

4. Which is a post streptococcal sequelae:
a. Acute rheumatic fever
b. Cellulitis
c. Pharyngitis
d. Impetigo

5. Neonatal meningitis acquired through infected birth canal is due to:
a. *S. pyogenes* b. Viridans streptococci
c. *S. agalactiae* d. *S. pneumoniae*

6. Carrom coin appearance of colonies is seen for:
a. *S. pyogenes* b. Viridans streptococci
c. *S. agalactiae* d. *S. pneumoniae*

7. Which is not a property of *S. pneumoniae*?
a. Bile solubility
b. Animal pathogenicity in mice
c. Growth in presence of 40% bile
d. Optochin sensitivity

Answers
1. a **2.** b **3.** b **4.** a **5.** c **6.** d **7.** c

CHAPTER 23

Neisseria and Moraxella

Chapter Preview

- Neisseria meningitidis
- Neisseria gonorrhoeae
- Commensal neisseria species
- Moraxella

Gram-negative cocci include *Neisseria, Moraxella catarrhalis* and *Veillonella* (the later is a non-sporing anaerobe described in Chapter 26).

Members of genus *Neisseriae* are catalase and oxidase positive, non-motile, aerobic gram-negative diplococci. Two species are pathogenic to humans—(1) *N. meningitidis* (causes pyogenic meningitis) and (2) *N. gonorrhoeae* (causes gonorrhea), both differ from each other in various aspects (Table 23.1). Other species are commensals of genital tract or oral cavity, such as *N. lactamica, N. flavescens, N. mucosa, N. sicca, N. subflava,* etc.

NEISSERIA MENINGITIDIS (MENINGOCOCCUS)

Meningococci are capsulated gram-negative diplococci with adjacent sides flattened (lens-shaped/half moon-shaped). Though it is a commensal in nasopharynx of healthy adolescents, invasive disease, such as meningitis or septicemia can occur in susceptible individuals.

TABLE 23.1: Differences between *Neisseria meningitidis* and *Neisseria gonorrhoeae*

N. meningitidis	*N. gonorrhoeae*
Capsulated	Noncapsulated
Lens-shaped/half moon-shaped (diplococci with adjacent sides flattened)	Kidney-shaped (diplococci with adjacent sides concave)
Ferment glucose and maltose	Ferments only glucose
Rarely have plasmids	Usually possess plasmids, coding for drug-resistant genes
Exist in both intra- and extracellular forms	Predominantly exist in intracellular form
Colony—circular	Colony—varies in size with irregular margin
Habitat—nasopharynx	Habitat—genital tract (urethra, cervix), rarely pharynx

Virulence Factors

Capsular Polysaccharide

It is the principal virulence factor of meningococci; protects the bacteria from complement-mediated phagocytosis.

- Based on the antigenic nature of the capsule, meningococci can be typed into 13 serogroups (A–D, X–Z, 29E, W135, H, I, J and L), among which only 5 serogroups—**A, B, C, Y, and W135**—account for the majority of cases of invasive disease.
- Other capsular serogroups and noncapsulated meningococci (16% of isolates are not capsulated) commonly colonize the nasopharynx of asymptomatic carriers and are rarely associated with invasive disease.

Other Virulence Factors

- **Outer membrane proteins:** They are the porin proteins present beneath the capsule, embedded in the outer membrane. They are of two types—PorA and PorB; both show antigenic variability and are responsible for serotyping (PorB) and serosubtyping (PorA) of meningococci.
- **LPS and endotoxin:** Like other gram-negative bacteria, meningococci possess endotoxins in their cell wall. Endotoxin binds to CD14 molecules on host cell surface, in association with Toll-like receptor-4 (TLR4). This inturn activates the endothelial cells by inducing release of various inflammatory mediators, such as tumor necrosis factor, interleukin (IL)-1, IL-6, IL-8, IL-10, plasminogen-activator inhibitor-1, etc. Endothelial injury is central to many clinical features of meningococcemia, such as:
  - Increased vascular permeability leading to loss of fluid and shock.
  - Intravascular thrombosis (due to activation of procoagulants) leading to disseminated intravascular coagulation (DIC).
  - Myocardial dysfunction

- **IgA proteases:** Cleave mucosal IgA
- **Transferrin binding proteins:** They help in uptake of iron from transferrin.

Epidemiology

Worldwide, nearly 5 lakh cases of meningococcal disease occur each year, and 10% of those die.

- **Patterns of disease:** There are several patterns of the disease noted:
  - Epidemic disease: It occurs mainly in Sub-Saharan Africa, usually due to serogroup A and also by W135.
  - Outbreaks: Clusters of cases occur in areas with increased transmission, mainly due to serogroup C (in semi-closed communities, such as schools, military camps, etc.).
  - Hyperendemic disease (>10 cases per 100,000 population): It occurs mainly due to serogroup B.
  - Sporadic cases can occur due to all important serogroups A, B, C, Y, and W135.
- **High prevalence area:** The Sub-Saharan belt of Africa (from Ethiopia to Senegal) is the most prevalent area for meningococcal infections.
- **Seasonality:** Meningococcal infections are common in winter and spring (cold and dry climate).
- **Age:** Meningitis is common in early childhood (3 months to 5 years) with a second peak occurring in adolescents (15–25 years of age).
- **Risk factors that promote colonization include:**
  - Overcrowding and semiclosed communities, such as schools, military and refugee camps
  - Travellers (Hajj pilgrims)
  - Smoking
  - Viral and *Mycoplasma* infection of respiratory tract.
- **Risk factors that promotes disease include:**
  - Deficiency of terminal complement components (C5–C9)
  - Hypogammaglobulinemia
  - Hyposplenism

Pathogenesis

Humans are the only natural host for meningococci. Most common source of infection is nasopharyngeal carriers (mainly children).

- **Mode of transmission:** It is by droplet inhalation and the portal of entry is nasopharynx.
- **Spread of infection:** From nasopharynx, meningococci reach the meninges either by: (1) hematogenous route causing septicemia (most common); or (2) by direct olfactory nerve spread through cribriform plate; or (3) rarely through conjunctiva.

Clinical Manifestations

Asymptomatic colonization is the most common presentation. Various manifestations include:

- **Rashes:** A non-blanching rash (petechial or purpuric) develops in more than 80% of the cases.
- **Septicemia:** It is attributed to endotoxin induced endothelial injury leading to increased vascular permeability and intravascular thrombosis.
- **Waterhouse–Friderichsen syndrome:** It is a severe form of fulminant meningococcemia, characterized by large purpuric rashes (purpura fulminans), shock, disseminated intravascular coagulation (DIC), bilateral adrenal hemorrhage and multiorgan failure.
- **Pyogenic meningitis:** It commonly affects young children (3–5 years of age). Presentation includes fever, vomiting, headache, neck stiffness—similar to any other bacterial meningitis, except for the presence of rashes.
- **Chronic meningococcemia:** It occurs rarely and is characterized by repeated episodes of petechial rash, fever, arthritis, and splenomegaly.
- **Postmeningococcal reactive disease:** Immune complexes (made up of capsular antigens and their antibodies) develop 4–10 days later, lead to manifestations like arthritis, rash, iritis, pericarditis, polyserositis, and fever.

LABORATORY DIAGNOSIS — Meningococcus

- **Specimen collection:** CSF, blood, nasopharyngeal swab
- **CSF examination**
  - First portion is centrifuged and used for:
    - Capsular antigen detection
    - Biochemical analysis: ↑CSF pressure, ↑protein and ↓glucose
    - Gram staining: Pus cells with gram-negative diplococci, lens-shaped
  - Second portion: Culture on blood agar, chocolate agar
  - Third portion is enriched in BHI broth
- **Nasopharyngeal swab culture:** on Thayer Martin medium
- **Biochemical tests**
  - Oxidase and catalase positive
  - Ferment glucose and maltose but not sucrose
- **Serogrouping:** by latex agglutination test
- **Serology:** Antibodies to capsular antigens (ELISA)
- **Molecular diagnosis:** By multiplex PCR

Laboratory Diagnosis

Specimen Collection

Important specimens include cerebrospinal fluid (CSF), blood and skin scrapings from petechial rashes from cases, and nasopharyngeal swabs from carriers.

- Specimens are collected in sterile container and transported immediately without any delay.
- CSF should be processed immediately. It should never be refrigerated as suspected agents of meningitis, such as meningococci and *Haemophilus influenzae* may die on refrigeration.

- **Blood culture:** Blood should be immediately injected into blood culture bottles (brain–heart infusion or BHI broth) and incubated overnight; subcultures are made onto blood agar and colonies grown are processed (as described for CSF later).
- Nasopharyngeal swabs, pus or scrapings from rashes should be carried in transport media (such as **Stuart's medium**) and inoculated onto selective media, such as **Thayer Martin medium** or **New York City medium** (to suppress the growth of normal flora).

CSF Examination

For bacteriological examination, the CSF is divided into the following three portions:

- **First portion** of CSF is centrifuged.
  - The supernatant is used for:
    - Capsular antigen detection by latex agglutination test.
    - Biochemical analysis: It reveals elevated CSF pressure, increased protein content and decreased glucose content.
  - The sediment is used for direct Gram staining: Meningococci appear as gram-negative diplococci (0.8 μm in size) with adjacent sides flattened (**lens** or **half-moon-shaped**), present inside the polymorphs, often extracellular also. This presumptive diagnosis helps to start empirical antibiotics (Fig. 23.1).
- **Second portion of CSF:** It is directly inoculated onto an enriched media, such as blood agar and chocolate agar and incubated for 24–48 hours at 37°C under 5–10% CO_2.
  - At 24 hours of incubation, colonies are small (1 mm), round, convex, grey, non-hemolytic, translucent. After 48 hours, colonies become larger with opaque raised center and thin transparent margin.
  - Meningococci are very delicate and fastidious; do not grow in basal media.
- **Third portion of CSF:** It is inoculated into enriched broth, such as BHI broth, incubated overnight till granular turbidity is produced and then subcultured onto blood agar and chocolate agar.

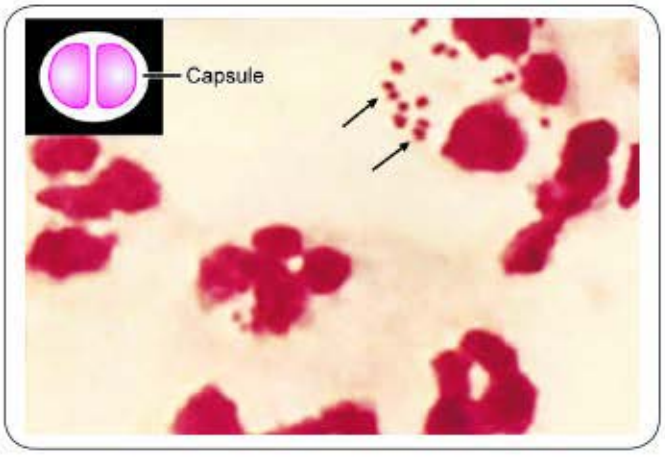


Fig. 23.1: Meningococci in CSF smear (gram-negative diplococci, lens-shaped) (arrows showing)

Source: Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Biochemical Tests

Biochemical tests should be carried out to differentiate meningococci from other commensal *Neisseria* species.

- Meningococci are catalase and oxidase positive.
- They ferment glucose and maltose but not sucrose. This can be tested by using rapid carbohydrate utilization test (RCUT).

Serogrouping

Serogrouping is done by slide agglutination test by using appropriate antisera.

Serology

Antibodies to capsular antigens can be detected by ELISA. This helps:

- In retrospective diagnosis of disease (as antibodies develop later in convalescent sera).
- To know the response to vaccination.
- In diagnosis of chronic meningococcemia.

Molecular Diagnosis

Multiplex PCR can be used for simultaneous detection of common agents of pyogenic meningitis. PCR is highly sensitive, detects even few bacteria in CSF, detects earlier than conventional culture and also helps in serogroup identification.

TREATMENT — Meningococcus

- **Drug of choice** is third-generation cephalosporins, such as ceftriaxone or cefotaxime, given for 7 days. Penicillin can also be given; however, reduced meningococcal sensitivity to penicillin has been reported from few countries.
- **Symptomatic treatment**, such as aggressive fluid resuscitation (for shock) and measures to decrease intracranial pressure.

Prevention

Chemoprophylaxis

Rifampicin and ciprofloxacin are the recommended drugs for chemoprophylaxis against meningococcal infections.

Vaccine Prophylaxis

Meningococcal polysaccharide vaccines are currently formulated as either bivalent (serogroups A and C) or quadrivalent (serogroups A, C, Y, and W135).

- **Dose:** 50 μg of each polysaccharide antigen per dose is

used, administered as two doses, 2–3 months apart to children of 3–18 months of age or a single dose to older children or adults.

- **Efficacy:** It has a protective efficacy rate of >95%. The duration of protection lasts for 3–5 years.
- **No vaccine is available for serogroup B because:**
  - Capsule of serogroup B (made up of sialic acid) is less immunogenic.
  - It is also encephalitogenic due to expression of similar cross reactive antigens on neural cells.
- **Not given below 3 years:** Similar to pneumococcal vaccine, meningococcal capsular vaccine is also an example of T-cell-independent antigen and is poorly immunogenic to children; hence not given to children of less than 2–3 years of age.
- **Conjugated vaccine**: However, conjugated meningococcal capsular vaccine is available which can be given to young children. Addition of a protein carrier (adjuvant) increases the immunogenicity of the capsular vaccine.

Outer Membrane Vesicles (OMVs)-based Vaccines

Vaccine trails based on outer membrane vesicles (OMVs) containing outer membrane proteins, phospholipid, and LPS have been used against Norwegian outbreak strain and had shown to reduce the incidence of group B disease.

NEISSERIA GONORRHOEAE (GONOCOCCUS)

Neisserea gonorrhoeae is noncapsulated, gram-negative kidney-shaped diplococci. It causes 'gonorrhea', a sexually transmitted infection (STI) and commonly manifests as cervicitis, urethritis and conjunctivitis.

Virulence Factors

- **Pili or fimbriae (hair-like structures):** Pili are the principal virulence factors of gonococci that help in adhesion to host cells and prevent bacteria from phagocytosis. Pili are composed of pilin proteins which are antigenically distinct, undergo antigenic and phase variation that help in typing of gonococci.
- **Outer membrane proteins:**
  - **Porin (protein I):** This accounts for more than 50% of total outer membrane proteins.
    - They form transmembrane channels (pores) which help in exchange of molecules across gonococcal surface.
    - There are two major serotypes—PorB.1A and PorB.1B serotypes. PorB.1A strains are often associated with both local and disseminated gonococcal infections (DGI), while PorB.1B strains usually cause local genital infections only.
  - **Opacity-associated protein (Protein II):** It helps in adhesion to neutrophils and other gonococci; and is also responsible for the opaque nature of gonococcal colonies.
- **Transferrin-binding and lactoferrin-binding proteins:** They help in uptake of iron from transferrin and lactoferrin.
- **IgA1 protease:** It protects the organism from the action of mucosal IgA antibody.
- **Lipo-oligosaccharide (LOS):** Here, the LPS is modified, consisting of only lipid A and core oligosaccharide but **lacks the repeating O side chain** which is seen in other gram-negative bacteria. It has marked endotoxic activity.

Typing of Gonococci

- **Serotyping:** It is based on protein-I (porin). Upto 24 protein-IA and 32 protein-IB have been identified.
- **Auxotyping:** It is based on nutritional requirements of the strains, e.g. AHU auxotype needs arginine, hypoxanthine and uracil as growth factors.

Clinical Manifestations

Gonorrhea is a venereal disease reported since ancient times; produces various infections in males, females and also in newborns.

- **In males:** Acute urethritis is the most common manifestation.
  - It is characterized by purulent urethral discharge (the word 'gonorrhea' is derived from flow of seed resembling semen, coined by Galen in 130AD).
  - The usual incubation period is 2–7 days.
  - Untreated cases may go for complications, such as epididymitis, prostatitis, edema of the penis, seminal vesiculitis and balanitis.
  - Infection may spread to periurethral tissues causing abscess with sinus formation (**water-can perineum**).
- **In females:** Gonococcal infection is less severe in females, with more asymptomatic carriage than males.
  - **Mucopurulent cervicitis:** It is the most common presentation.
  - **Vulvovaginitis:** It is not seen in adult females as the adult vagina is resistant to gonococcal infection (due to its low pH and thick stratified squamous epithelium). However, gonococcal vaginitis can occur in prepubertal girls and postmenopausal women where the vagina is lined by thinned out mucosa with higher pH.
  - **Spread:** Infection may spread to Bartholin's gland, endometrium and fallopian tube. Salpingitis and pelvic inflammatory disease may lead to sterility.
  - **Fitz–Hugh–Curtis syndrome:** It is a rare complication, characterized by peritonitis and associated perihepatic inflammation.
- **In both the sexes:** The following manifestations may

occur in both the sexes:

- Anorectal gonorrhea (spread by anal sex): It can be seen in females or rarely in males who have sex with men and present as acute proctitis. Rectal isolates are usually multi drug-resistant.
- Pharyngeal gonorrhea (spread by orogenital sex)
- Ocular gonorrhea

- **In pregnant women:** Gonococcal infection causes prolonged rupture of the membranes, premature delivery, chorioamnionitis, and sepsis in the infant.
- **In neonates (Ophthalmia neonatorum):** It is characterized by purulent eye discharge, occurs within 2–5 days of birth. Transmission occurs during birth from colonized maternal genital flora.
- **Disseminated gonococcal infection (DGI):** It occurs rarely following gonococcal bacteremia. DGI is characterized by polyarthritis and rarely dermatitis and endocarditis. It is most commonly associated with PorB.1A serotypes which are also characterized as AHU auxotypes.
- **In HIV-infected persons**: Nonulcerative gonorrhea enhances the transmission of HIV by three-to-five folds, possibly because of increase viral shedding.

Epidemiology

The incidence of gonorrhea has come down in developed countries; however, it still remains a public health problem in developing countries, and may play a role in enhancing transmission of HIV. Because of the associated social stigma, it is often under-reported.

- **Host:** Gonorrhea is an exclusively human disease, there are no animal reservoirs.
- **Source:** The only source of infection are asymptomatic female carriers or less often a patient.
- **Transmission:** It is almost exclusively transmitted—(1) by sexual contact (venereal); transmission from males to females is more efficient than in the opposite direction, (2) from mother to baby during birth.

LABORATORY DIAGNOSIS — Gonococcus

- **Specimen:** Urethral swab in men and cervical swab in women
- **Transport media:** Stuart's and Amies transport medium
- **Microscopy:** Gram-negative intracellular kidney-shaped diplococci
- **Culture**
  - Thayer Martin medium
  - Modified New York City medium
- **Biochemical tests**
  - Oxidase and catalase positive
  - Ferments only glucose but not maltose

Laboratory Diagnosis

Specimen Collection

Urethral swab in men and cervical swab in women are the preferred specimens. Vaginal swab is not satisfactory.

- The urethral meatus is cleaned with gauze soaked in saline. The purulent discharge is expressed out by pressing at the base of the penis and collected directly on to slides or swabs.
- **Dacron or rayon swabs** are preferred, as cotton and alginate swabs are inhibitory to gonococci.
- **In chronic urethritis:** As discharge is minimal, prostatic massage is done to collect the secretion; alternatively, the morning drop of secretion may be collected.

Transport Media

Specimens should be transported immediately. If not possible, then it should be collected in charcoal-coated swabs kept in **Stuart's** transport medium or, alternatively, charcoal containing medium (**Amies** medium) can be used. Currently, various commercial transport devices, such as JEMBEC or Gono-Pak system are available.

Microscopy

Gram staining of urethral exudates reveals gram-negative intracellular kidney-shaped diplococci (Fig. 23.2). Gram staining is highly specific and sensitive in symptomatic men. However in females, it is only 50% sensitive because, the presence of commensal *Neisseria* species may confound with interpretation. Hence, culture is recommended for diagnosis of gonorrhea in women.

Culture

Endocervical culture has a sensitivity of 80–90%. As cervical swabs contain normal flora, hence, selective media are preferred, such as:

Fig. 23.2: Gonococcus (gram-negative diplococci, kidney-shaped)

Source: Public Health Image Library, ID# /2108, Centers for Disease Control and Prevention (CDC), Atlanta *(with permission)*

- **Thayer Martin medium** is chocolate agar added with vancomycin, colistin and nystatin. It inhibits commensal *Neisseria* species.
- **Modified New York City medium:** Lysed blood agar and lincomycin, colistin, trimethoprim and amphotericin B.
- **Martin–Lewis medium**

Inoculated media are incubated at 37°C for 24–48 hours. Colonies on Thayer Martin media are large 1.5–2.5 mm, grey, convex, with crenated margin and raised opaque center. In contrast to meningococci, the colonies of gonococci vary in size with irregular outline.

Blood and synovial fluid cultures should be done in suspected cases of DGI on enriched media, such as lysed blood agar (by saponin) and chocolate agar.

Biochemical Tests

Biochemical tests should be carried out to differentiate gonococci from other commensal *Neisseria* species.

- Gonococci are catalase and oxidase positive.
- They ferment only glucose, but not maltose and sucrose. This can be tested by rapid carbohydrate utilization test (RCUT).

TREATMENT Gonococcus

- **Drug of choice:** Third generation cephalosporins currently are the mainstay of therapy for uncomplicated gonococcal infection. Both the sexual partners should be treated.
  - Ceftriaxone (250 mg given IM, single dose)
  - Cefixime (400 mg given orally, single dose)
- If coexisting chlamydial infection is present, then azithromycin or doxycycline can be added to the regimen.

Drug Resistance in *Neisseria gonorrhoeae*

Gonococci were initially susceptible to most antibiotics, such as sulfonamides, penicillins, quinolones, but because of their continual usage, resistance has emerged over the time.

Various resistant strains have evolved in due course of time (Table 23.2). The strains are often resistant to many drugs at a time.

Though third-generation cephalosporins are the drugs of choice for gonococcal infections at present, some strains show reduced susceptibility to ceftriaxone and cefixime (termed as cephalosporin intermediate/resistant strains), which may be due to altered penicillin-binding protein 2.

Prophylaxis

There is no vaccination available for gonoccci. The general prophylactic measures include:

- Early detection of cases
- Treatment of both partners
- Tracing of contacts
- Health education about safe sex practices, such as use of condoms

TABLE 23.2: Drug resistance in gonococci

Drug resistance in gonococci	
PPNG	Penicillinase producing strains of *Neisseria gonorrhoeae*: ▪ Originated from Africa and Asia in 1976; later on, spread worldwide ▪ Plasmids coding for β-lactamases are transferred horizontally by conjugation
CMRNG	Chromosomally mediated resistant *N. gonorrhoeae*: ▪ Show resistance to penicillin and also to tetracycline ▪ It is due to mutations at multiple sites, which decrease the permeability of the cell to antibiotics
TRNG	Tetracycline-resistant *N. gonorrhoeae*; plasmid-borne
QRNG	Quinolone-resistant *N. gonorrhoeae*

Nongonococcal (Nonspecific) Urethritis (NGU)

Chronic urethritis where gonococci cannot be demonstrated has been labeled as nongonococcal urethritis. NGU is more common than gonococcal urethritis.

Several agents are implicated in NGU such as:

- **Bacteria:**
  - *Chlamydia trachomatis*—most common agent
  - *Ureaplasma urealyticum*
  - *Mycoplasma hominis*
  - Some cases may be due to gonococcal infection, the cocci persisting as L forms and, hence, undetectable by routine tests.
- **Viruses:** Herpes simplex virus, and cytomegalovirus
- **Fungi:** *Candida albicans*
- **Parasites:** *Trichomonas vaginalis*

Differences between gonococcal and nongonococcal urethritis are given in Table 23.3.

COMMENSAL NEISSERIA SPECIES

Several species of neisseriae are harmless commensals of human respiratory tract; however, occasionally they cause human disease. They can be differentiated from pathogenic neisseriae by various ways, such as:

- They can grow on basal media, such as nutrient agar.
- They can grow at 22°C.
- Mostly, they do not grow on selective media (except *N. lactamica*).
- Not capnophilic (CO_2 is not required).
- Ferment a number of carbohydrates.
- ONPG test for β-galactosidase is positive by *N. lactamica*.
- Some are pigmented—*N. flava* and *N. flavescens*
- Some are capsulated—*N. mucosa*
- Some are rod-shaped—*N. elongata* and *N. weaveri*.

MORAXELLA

Moraxella includes *M. catarrhalis* and *M. lacunata*.

Moraxella catarrhalis

Moraxella catarrhalis (previously classified under *Branhamella* or *Neisseria*) is a harmless commensal of upper respiratory tract and genital tract.

TABLE 23.3: Differences between gonococcal and nongonococcal urethritis

Features	Gonococcal urethritis (GU)	Nongonococcal urethritis (NGU)
Onset	48 hours	Longer (>1 week)
Urethral discharge	Purulent (flow like seed-resembling semen)	Mucous to mucopurulent
Complication	DGI (polyarthritis and endocarditis) Water-can perineum	**Reiter's syndrome:** Characterized by conjunctivitis, urethritis, arthritis and mucosal lesions
Diagnosis	▪ Gram stain ▪ Culture on Thayer Martin media	▪ For *Chlamydia*—culture on McCoy and HeLa cell lines ▪ For *Trichomonas*—detection of trophozoite ▪ For *Candida*—detection of budding yeast cells in discharge ▪ For PCR—can be done for HSV or *Chlamydia*
Treatment	Ceftriaxone	▪ For *Chlamydia*—Doxycycline ▪ For *Trichomonas*—Metronidazole ▪ For *Candida*—Clotrimazole (as vaginal cream or tablet)

Abbreviations: DGI, disseminated gonococcal infection; GU, gonococcal urethritus; NGU, nongonococcal urethritus; HSV, herpes simplex virus

- **Morphology:** Gram-negative diplococci, 0.6–1 μm oval with flattened adjacent sides.
- **Culture:** It grows on basal medium like nutrient agar.
- **Biochemical reactions:** It is catalase and oxidase positive. It differs from pathogenic *Neisseria* as:
  - It does not ferment any carbohydrate.
  - Gives a positive tributyrin hydrolysis test.
  - Shows DNase test positive.
- **Pathogenesis:** It causes opportunistic lower respiratory tract infections, especially in adults with chronic obstructive airway disease.
- It has also been isolated in cases of otitis media, less commonly in meningitis, endocarditis and sinusitis.
- Some strains of *M. catarrhalis* secrete beta-lactamases which destroy penicillin that makes β-lactam antibiotics ineffective to meningococci and other penicillin-sensitive bacteria of the respiratory tract.

Moraxella lacunata

It is also called Morax-Axenfeld bacillus. It is non-fermenting gram-negative rod-shaped and generally present as pairs. It causes catarrhal conjunctivitis, and angular conjunctivitis.

EXPECTED QUESTIONS

I. Essay:

1. Describe the virulence factors, pathogenesis and laboratory diagnosis of *Neisseria meningitidis.*
2. Kallu, a 25-year-old heterosexual male from Chennai came with history of dysuria and noted some 'pus-like' drainage in his underwear and at the tip of his penis. He gave a history of being sexually active with five or six partners in the past 6 months. His physical examination showed yellow urethral discharge and tenderness at the tip of the penis. Examination of the urethral discharge revealed intracellular gram-negative diplococci with plenty of pus cells.
   a. What is the clinical diagnosis and the causative agent?
   b. Describe the pathogenesis of this condition ?
   c. How will you confirm the diagnosis?

II. Write short notes on:

1. Meningococcal vaccines
2. Nongonococcal urethritis (NGU)

III. Multiple Choice Questions (MCQs):

1. The most common mode of transmission of gonorrhoea is:
   a. Venereal mode
   b. Injection
   c. Blood transfusion
   d. Inhalation

2. All of the following are causative agents of NGU except:
   a. *Chlamydia trachomatis*
   b. *Mycoplasma hominis*
   c. *Candida albicans*
   d. Meningococci

3. All of the following meningococcal serogroups cause invasive disease except:
   a. W135
   b. A
   c. D
   d. Y

4. Gonococci can be differentiated by meningococci by following sugar fermentation test:
   a. Glucose
   b. Sucrose
   c. Mannitol
   d. Maltose

Answers

1. a **2.** d **3.** c **4.** d

CHAPTER 24

Corynebacterium

Chapter Preview

- Corynebacterium diphtheriae
- Other coryneform bacteria

Corynebacteria are gram-positive, non-capsulated, non-sporing, non-motile rods. They are irregularly stained and frequently show **club-shaped swellings** (Fig. 24.1A) (Greek word *koryne*, meaning club). *Corynebacterium diphtheriae*, the causative agent of **diphtheria** is the most important species pathogenic to man; other species are occasionally pathogenic, such as *C. ulcerans* and *C. pseudotuberculosis*.

CORYNEBACTERIUM DIPHTHERIAE

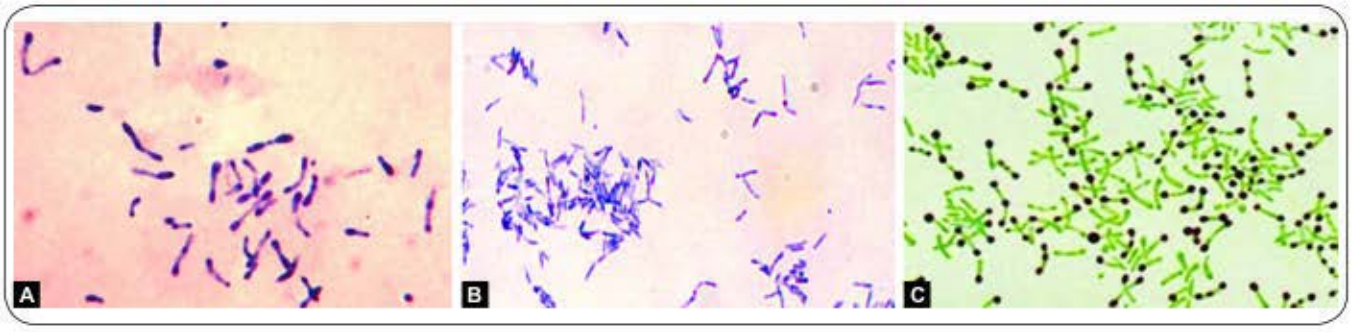
C. diphtheriae is club-shaped, irregularly stained gram-positive pleomorphic rod that typically shows two characteristic features:

1. **Chinese letter or cuneiform** arrangement: They appear as V- or L-shaped in smear, which is due to the bacterial cells divide horizontally and daughter cells tend to lie at acute angles to each other. This type of cell division is called **snapping type of division** (Fig. 24.1B).
2. **Metachromatic granules:** They are present at ends or poles of the bacilli (also called polar bodies or Babes–Ernst bodies or volutin granules).
   - They are storage granules of the organism, composed of polymetaphosphates.
   - Granules are stained strongly gram-positive compared to remaining part of the bacilli. The granules take up bluish purple metachromatic color when stained with Loeffler's methylene blue.
   - However, they are better stained with special stains, such as Albert's, Neisser's and Ponder's stain (Fig. 24.1C).
   - Granules are well developed on enriched media, such as blood agar or Loeffler's serum slope.
   - Volutin granules can also be possessed by other organisms such as—by *C. xerosis* and *Gardnerella vaginalis*.

History

Diphtheria is an ancient disease, known since the time of Hippocrates.

- Diphtheria was first recognized by Pierre Bretonneau (1826). He used the term diphthérite (Greek word *diphtheros*—meaning leather like) to describe the characteristic manifestation, i.e. leathery pseudomembrane formation over tonsil.



Figs 24.1A to C: *Corynebacterium diphtheriae*. **A.** Club-shaped bacilli in methylene blue-stained smear; **B.** Gram-stained smear shows V- or L-shaped bacilli with cuneiform arrangement; **C.** Albert's stain shows dark blue metachromatic granules at the ends of the bacilli

Source: Public Health Image Library, A. ID# /7323/P.B. Smith, B. ID# /1943, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- *C. diphtheriae* was first observed by Klebs (1883) and first cultivated by Loeffler (1884); hence, it is known as **Klebs-Loeffler bacillus**.
- Roux and Yersin (1888) established the pathogenic effect of diphtheria toxin; subsequently, its antitoxin was described by Von Behring (1890).

Virulence Factors (Diphtheria Toxin)

Diphtheria toxin (DT) is the primary virulence factor responsible for diphtheria.

- The toxin is synthesized in precursor form of molecular weight 58,700 kDa containing a polypeptide made up of 535 amino acids.
- Toxin has two fragments; A (active) and B (binding) of molecular weight 21,500 and 37,200 kDa respectively.
- Fragment B is the binding fragment which binds to the host cell receptors (such as epidermal growth factor) and helps in entry of fragment A.
- Fragment A is the active fragment, gets internalized into the cell and then acts by the mechanism given below.

Mechanism of Diphtheria Toxin (DT)

- Fragment A is the active fragment, which causes ADP ribosylation of elongation factor 2 (EF-2) → leads to inhibition of EF-2 → leads to inhibition of translation step of protein synthesis.
- Exotoxin A of *Pseudomonas* has a similar mechanism like that of DT.

Factors Regulating Toxin Production

The production of diphtheria toxin is dependent on various factors.

- **Phage coded:** DT is coded by a bacteriophage called β-corynephage, carrying *tox* gene. *C.diphtheriae* remains toxigenic as long as the phages are present inside the bacilli (lysogenic conversion).
- **Iron concentration:** The toxin production depends on optimum concentration of iron (0.1 mg per liter). Higher level of iron inhibits toxin synthesis by upregulating DT repressor gene in the bacterial chromosome.
- **DT repressor** gene (DtxR): It is an iron-dependent negative regulator of DT production and iron uptake in *C. diphtheriae*.
- **Biotypes:** Among the three biotypes of *C. diphtheriae*, (described later, Table 24.1) all strains of gravis, 95–99% strains of intermedius and 80–85% of mitis strains are toxigenic. However, toxins produced by different biotypes are antigenically similar.
- **Other species:** DT is also produced by *C. ulcerans* and *C. pseudotuberculosis*.

Toxoid is used for Vaccination

Diphtheria toxin is antigenic and antitoxins are protective in nature. However, as it is virulent, it cannot be given directly for vaccination.

- Toxin can be converted to toxoid which is used for vaccination. Toxoid is a form of toxin, where the virulence is lost, retaining its antigenicity.
- Toxoid formation is promoted by formalin, acidic pH and prolonged storage.
- **Park William 8** strain of *C. diphtheriae* is used as a source of toxin for the preparation of vaccine.
- **LF unit:** DT is expressed as Loeffler's flocculating (Lf) unit. 1 Lf unit is the amount of toxin which flocculates most rapidly with one unit of antitoxin.

Pathogenicity and Clinical Manifestations

Pathogenesis of diphtheria is toxin mediated.

- Diphtheria is toxemia but never a bacteremia.
- Bacilli are noninvasive, present only at local site (pharynx), secrete the toxins which spread by bloodstream to various organs.
- It is the toxin which is responsible for all types of manifestations including local (respiratory) and systemic complications (except the skin lesions, which is caused due to the organism, not toxin).

Respiratory Diphtheria

This is the most common form of diphtheria. Tonsil and pharynx (faucial diphtheria) are the most common sites followed by nose and larynx. Incubation period is about 3–4 days.

- **Faucial diphtheria:** Diphtheria toxin elicits an inflammatory response, that leads to necrosis of the epithelium and exudate formation.
  - This leads to formation of mucosal ulcers, lined by a tough leathery greyish white **pseudomembrane coat;** composed of an inner band of fibrin surrounded by neutrophils, RBCs and bacteria (Fig. 24.2A).
  - It is so named as it is adherent to the mucosal base and bleeds on removal, in contrast to the true membrane which can be easily separated.
- **Extension of pseudomembrane:** In severe cases, it may extend into the larynx and bronchial airways, which may result in fatal airway obstruction leading to asphyxia. This mandates immediate tracheostomy.
- **Bull-neck appearance:** It is characterized by massive tonsillar swelling and neck edema. Patients present with foul breath, thick speech, and stridor (noisy breathing) (Fig. 24.2B).

Cutaneous Diphtheria

It presents as punched-out ulcerative lesions with necrosis, or rarely pseudomembrane formation; most commonly occur on the extremities (Fig. 24.3).

- Cutaneous diphtheria is due to the organism itself and is not toxin-mediated. Hence it is possible that, the skin lesions may also be caused by nontoxigenic strains.

Figs 24.2A and B: A. Pseudomembrane covering the tonsils classically seen in diphtheria and **B.** Bull neck appearance (arrow showing)

Source: A. Wikipedia/Dileepunnikri and B. Public Health Image Library/ID#5325, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Fig. 24.3: Cutaneous diphtheria

Source: Public Health Image Library,ID# /1941, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- There is increasing trend of cutaneous diphtheria now a days, especially in vaccinated children; because antitoxins present in vaccinated people cannot prevent the disease.

Systemic Complications

Polyneuropathy and myocarditis are the late toxic manifestations of diphtheria, occurring after weeks of infection. Other complications of diphtheria include pneumonia, renal failure, encephalitis, cerebral infarction, and pulmonary embolism.

- **Neurologic manifestations**: It is a toxin mediated non-inflammatory demyelinating disorder; presented with:
  - Cranial nerve involvement
  - Peripheral neuropathy
  - Ciliary paralysis
- **Myocarditis:** It is typically associated with arrhythmias and dilated cardiomyopathy.

LABORATORY DIAGNOSIS — *Corynebacterium diphtheriae*

Isolation of the *Corynebacterium diphtheriae*

- **Specimen:** Throat swab and a portion of membrane
- **Direct smear**
  - Gram-stain: Club shaped gram-positive bacilli with Chinese letter arrangement
  - Albert's stain: Green bacilli with bluish black metachromatic granules
- **Culture media**
  - Enriched medium: Blood agar, chocolate agar and Loeffler's serum slope
  - Selective medium: Potassium tellurite agar and Tinsdale medium, produces black colonies
- **Biochemical identification**
  - Hiss's serum sugar media: ferments glucose, maltose and/or starch
  - Urease test negative

Diphtheria Toxin Demonstration

- *In vivo* tests (Guinea pig inoculation)—subcutaneous and intracutaneous tests
- *In vitro* tests
  - Elek's gel precipitation test
  - Detection of *tox* gene-by PCR
  - Detection of toxin-by ELISA or ICT
  - Cytotoxicity on cell lines

Laboratory Diagnosis

The diagnosis of diphtheria is based on clinical signs and symptoms plus laboratory confirmation.

- Because of the risk of respiratory obstruction, specific treatment should be instituted immediately on clinical suspicion without waiting for laboratory reports.
- Laboratory diagnosis is necessary only for:
  - Confirmation of clinical diagnosis
  - Initiating the control measures
  - Epidemiological purposes

Laboratory diagnosis consists of isolation of the bacilli and toxin demonstration.

Isolation of the Diphtheria Bacilli

Specimen

Useful specimens include—(1) throat swab (one or two) containing fibrinous exudates, (2) a portion of pseudomembrane (3) nose or skin specimens (if infected).

Direct Smear Microscopy

- **Gram-stain:** *C. diphtheriae* appear as irregularly stained club-shaped gram-positive bacilli of 3–6 μm length, typically arranged in **Chinese letter** or **cuneiform**

arrangement (V- or L-shaped). It is difficult to differentiate them from other commensal coryneforms found in the respiratory tract (Fig. 24.1B).

- **Albert's stain:** It is more specific for *C. diphtheriae,* as they appear as green bacilli with bluish black metachromatic granules (Fig. 24.1C).

Culture Media

Enriched Medium

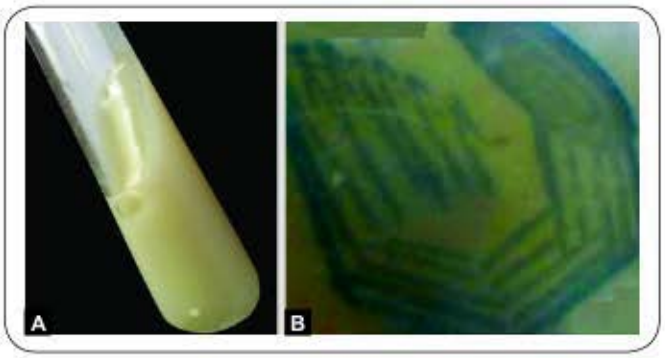
C. diphtheriae is fastidious, aerobe and facultative anaerobe; does not grow on ordinary medium. It grows best in enriched medium such as blood agar, chocolate agar and Loeffler's serum slope. Plates are incubated at 37°C aerobically.

- **Blood agar:** Colonies are small circular, white and sometimes hemolytic (mitis biotype).
- **Loeffler's serum slope:** It is composed of nutrient broth with horse or sheep serum and glucose (Fig. 24.4A).
  - Colonies appear as small, circular, glistening, and white with a yellow tinge in 6–8 hours.
  - Advantages—(1) Growth can be detected as early as 6-8 hours. (2) Best medium for metachromatic granules production.
  - Disadvantage—As it is an enriched medium, if incubated beyond 6–8 hours, it supports growth of other throat commensals also.

Selective Medium

Selective media are best for isolation of *C. diphtheriae* from cases as well as from carriers; as the normal flora will be inhibited. Selective media used are:

- **Hoyle's potassium tellurite agar (PTA):** It contains lysed horse blood agar and potassium tellurite (0.04%) as inhibiting agent.
  - *C. diphtheriae* reduces tellurite to metallic tellurium which gets incorporated into the colonies giving them black color (Fig. 24.4B). *C. ulcerans* and *C. pseudotuberculosis* can also grow on PTA producing black colored colonies.



Figs 24.4A and B: **A.** Loeffler's serum slope; **B.** Potassium tellurite agar shows black colonies

  - Advantage: Throat commensals are inhibited.
  - Disadvantage: Colonies appear only after 48 hours of incubation.
- **Tinsdale medium:** It is a modified PTA added with cysteine. Black-colored colonies are produced, surrounded by a brown halo, due to breakdown of cysteine by cysteinase enzyme produced by the organism.

Biochemical Identification

- **Hiss's serum sugar media:** Diphtheria bacilli ferment glucose and maltose (by all biotypes) and starch (by only gravis biotype), with the production of acid but no gas. As it is fastidious, only enriched sugar media such as Hiss's serum sugar media can be used for testing sugar fermentation test.
- **Pyrazinamidase test:** It is positive for *C. diphtheriae, C. ulcerans* and *C. pseudotuberculosis* which produce pyrazinamidase enzyme, that breaks down pyrazinamide.
- **Urease test:** *C. diphtheriae* does not hydrolyze urea. This property differentiates it from *C. ulcerans* and *C. pseudotuberculosis* which are urease positive.
- *Corynebacterium* is catalase positive but oxidase negative and nonmotile.

Toxin Demonstration

As the pathogenesis is due to diphtheria toxin, mere isolation of bacilli does not complete the diagnosis. Toxin demonstration should be done following isolation, which can be of two types—*in vivo* and *in vitro*.

In vivo Tests (animal inoculation)

- **Subcutaneous test:** 0.8 mL of the culture broth of the test stain is injected subcutaneously into two guinea pigs, one of which has been protected with 500 units of the diphtheria antitoxin on the previous day. If the strain is virulent (toxigenic), the unprotected animal will die within four days.
- **Intracutaneous test:** It is slightly different from the subcutaneous test.
  - 0.1 mL of culture broth is inoculated intracutaneously into two guinea pigs (or rabbits).
  - One animal acts as the control and should receive 500 units of antitoxin on the previous day.
  - The other, i.e. test animal is given 50 units of antitoxin intraperitoneally 4 hours after the skin test, in order to prevent death.
  - Toxigenicity is indicated by necrosis of the inoculated site of the test animal in 48–72 hours. The control animal shows no change.
  - **Advantages:** There is no death of animals. Many strains can be tested at a time on the same animal.

In Vitro Test

- **Elek's gel precipitation test:** This is a type of immunodiffusion in gel described by Elek (1949).
  - A rectangular strip of filter paper soaked in diphtheria antitoxin (1000 units per mL) is placed on the surface of a 20% horse (or sheep or rabbit) serum agar plate before the medium solidifies.
  - When the agar solidifies, the test strain is streaked at right angle to the filter paper strip. The plate is incubated at 37°C for 24–48 hours.
  - **Precipitation band:** If the strain is toxigenic, the toxin diffuses in the agar, meets with the antitoxin and produces arrow-shaped precipitation band.
  - Nontoxigenic stains will not produce any precipitation line (Fig. 24.5).
  - This test can also be used to know the relatedness between the strains isolated during an outbreak. The precipitate lines would fuse with each other if the toxins produced by the strains are identical. (Figure 12.5 of Chapter 12).
- **Other *in vitro* tests** include:
  - Detection of *Tox* gene by PCR
  - Detection of diphtheria toxin by ELISA or immunochromatographic test (ICT).
  - Cytotoxicity produced on cell lines.

Typing of *C. diphtheriae*

Typing methods are useful for epidemiological studies, to know the relatedness between the isolates. Several methods available for typing of *C. diphtheriae*.

- **Biotyping (McLeod's classification):** *C. diphtheriae* can be typed into four biotypes such as gravis, intermedius, mitis and belfanti based on various properties (Table 24.1). Biotype belfanti is a nitrate negative variant of mitis biotype.

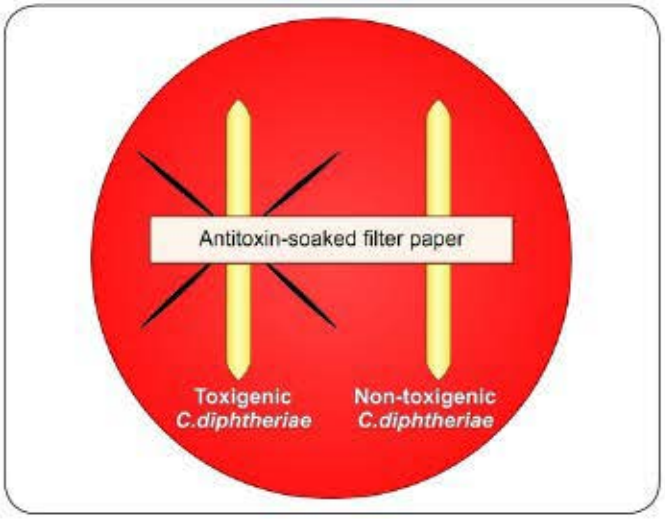


Fig. 24.5: Elek's gel precipitation test

TABLE 24.1: Biotypes of *Corynebacterium diphtheriae* (McLeod's classification)

	Biotypes		
Properties	***gravis***	***intermedius***	***mitis***
Morphology	Short, no granules	Long barred, poor granules	Long curved, prominent granules
Colonies on PTA	**'Daisy head'** colony	**'Frog's egg'** colony	**'Poached egg'** colony
Colony consistency	Brittle, not emulsifiable	In-between gravis and mitis	Soft, buttery, emulsifiable
Starch fermentation	+ve	-ve	-ve
Toxigenic strains	100%	95–99%	80–85%
Virulence	Severe	Moderate	Mild
Occurrence	Epidemic	Epidemic	Endemic
Complications	Paralytic and hemorrhagic	Hemorrhagic	Obstructive
Hemolysis	Variable	Non-hemolytic	Hemolytic

Abbreviation: PTA, potassium tellurite agar

- **Serotyping:** *C. diphtheriae* can be typed based on antigens such as mycolic acid, heat stable polysaccharide antigen and heat labile protein antigen.
- **Bacteriophage typing:** It is based on the sensitivity of the strains of *C. diphtheriae* to the lytic action of standard phages.
- **Bacteriocin typing:** It is based on the ability of the test strain producing bacteriocin (*diphthericin*) to kill standard indicator strains of bacteria.
- **Molecular typing** methods, such as pulse field gel electrophoresis and restricted fragment length polymorphism can be used.

Epidemiology

Worldwide, there is declining trend of diphtheria cases in most countries including India, due to widespread vaccination coverage.

- **Source of infection:** Carriers (95%) are more common source of infection than cases (5%).
- **Carriers:** They may be temporary (persist for a month) or chronic (persist for a year). Nasal carriers are more dangerous due to frequent shedding than throat carriers. Incidence of carrier rate varies from 0.1 to 5%.
- **Transmission** is via the aerosol route, or rarely by contact with infected skin lesions.
- **Reservoir:** Humans are the only reservoir.
- **Age:** Diphtheria is common in children aged 1–5 years. With wide spread immunization, a shift in the age has been observed from preschool to school age. Newborns are usually protected due to maternal antibodies.

TREATMENT ***Corynebacterium diphtheriae***

Treatment should be started immediately on clinical suspicion of diphtheria.

- **Antidiphtheritic serum or ADS (antitoxin):** Passive immunization with antidiphtheritic horse serum is the treatment of choice as it neutralizes the toxin.
  - A trial dose should be given to check for hypersensitivity.
  - It is given either IM or IV and the dose varies depending on the severity.
    - Mild, early pharyngeal cases: 20,000–40,000 units.
    - Moderately severe cases: 40,000–60,000 units.
    - Severe, extensive or late cases (>3days): 80,000–1,00,000 units.
- **Antibiotics:** Penicillin or erythromycin is the drug of choice. Antibiotic plays a minor role as it is of no use once the toxin is secreted. However, antibiotics are useful:
  - If given early (<6 hrs of infection), before the toxin release
  - Prevent further release of toxin by killing the bacilli
  - Treatment of cutaneous diphtheria
  - Treatment of carriers—drug of choice is erythromycin.

Prophylaxis (Vaccination)

Active immunization is done with diphtheria toxoid as it induces antitoxin production in the body. A protective titre of more than 0.01 Unit/mL of antitoxin can prevent all forms of diphtheria.

However, vaccine is not effective for:

- Prevention of cutaneous diphtheria
- Elimination of carrier stage

Types of Vaccine

- **Single vaccine:** Diphtheria toxoid (alum or formal precipitated)
- **Combined vaccine:** Various vaccines available are—
  - DPT: Contains **D**T (diphtheria toxoid), **P**ertussis (whole cell) and **T**T (tetanus toxoid)
  - DaPT: Contains DT, TT and acellular pertussis (aP)
  - DT: Contains DT and TT
  - dT: Contains TT and adult dose diphtheria toxoid (d)

DPT Vaccine

Among the vaccine preparations available, DPT is the preparation of choice for vaccinating infants, because:

- Infants can be immunized simultaneously against three important childhood diseases—diphtheria, tetanus and pertussis by single injection.
- **Pertussis** component acts as **adjuvant** and increases immunogenicity of DT and TT.

Types

Diphtheria toxoid is prepared by two methods:

1. **Plain formol toxoid** (or fluid toxoid): Toxoid is prepared by incubating toxin with formalin.
2. **Adsorbed (alum adsorbed):** Formol toxoid is adsorbed on to alum. Alum (Aluminum phosphate, to less extent Aluminum hydroxide) acts as adjuvant and increases the immunogenicity of toxoid.

Administration of DPT

- **Schedule:** DPT is included under national immunization schedule of India. Total five doses are given; three doses at 6, 10 and 14 weeks of birth followed by two booster doses at 16–24 months and 5 years.
- **Site:** DPT is given deep intramuscularly (IM) at antero-lateral aspect of thigh, (gluteal region is not preferred as fat may inhibit DPT absorption).
- **Thiomersal** (0.01%) is used as preservative.
- **Storage:** DPT should be kept at 2–8°C, if accidentally frozen then it has to be discarded.
- **Dose:**

  One dose (0.5 mL) of vaccine contains:
  - **Glaxo:** 25 Lf (DT), 5 Lf (TT), 20,000 million (pertussis killed bacilli).
  - **Kasauli:** 30 Lf (DT), 10 Lf (TT), 32,000 million (pertussis killed bacilli).
- **Protective titer:** Following vaccination, an antitoxin titer of ≥ 0.01 unit/mL is said to be protective.
- **dT:** It contains TT and adult dose (2 Lf) of diphtheria toxoid. dT is given to adults more than 12 years (3 doses at 0, 1 month, and 1 year).

Adverse Reactions following DPT Administration

- **Mild:** Fever and local reaction (swelling and indurations) are observed commonly.
- **Severe:** Whole cell killed vaccine of *B. pertussis* is encephalitogenic. It is associated with neurological complications. Hence, DPT is not recommended after 6 years of age.
- **Absolute contraindication to DPT:**
  - Hypersensitivity to previous dose
  - Progressive neurological disorder
- **Acelluar pertussis (aP) vaccine:** This form of pertussis vaccine is devoid of neurological complication and is given safely to older children (DaPT).

Schick Test

It is a toxin-antitoxin neutralization test, obsolete now a days.

- It was in use long back when the vaccine was introduced initially. The test was carried out on the people before starting immunization.
- Susceptible individuals used to develop erythema and induration on test arm following intradermal inoculation of the toxin. Vaccine was administered only to those susceptible people. Since now safer toxoid preparations are available, Schick test is not performed.

DIPHTHEROIDS OR NONDIPHTHERIAL CORYNEBACTERIA

Diphtheroids

Diphtheroids or coryneforms are the nondiphtherial corynebacteria, that usually exist as normal commensals in the throat, skin, conjunctiva and other areas. However, they have been associated with invasive disease, particularly in immunocompromized patients. They can be differentiated from *C. diphtheriae* by many features such as:

- Stains more uniformly than *C. diphtheriae*
- Palisade arrangement: Arrange in parallel rows rather than cuneiform pattern (Fig. 24.6)
- Absence of metachromatic granules (except *C. xerosis*)
- Toxigenicity or virulence test—negative
- Biochemical reactions may be different from *C. diphtheriae*—e.g. ferments sucrose (*C. xerosis*).

Coryneforms that are rarely pathogenic to man are:

- **Clinically resembling diphtheria:** *C. ulcerans* and *C. pseudotuberculosis* produce diphtheria toxin and cause localized ulcerations in throat, clinically resembling diphtheria. They also produce black colored colony with brown halo on Tinsdale medium similar to *C.diphtheriae*. However, both give a positive urease test, thus can be differentiated from *C.diphtheriae* which is urease negative.
  - *C. ulcerans* causes infections in cows and human infections may occur through cow's milk.
  - *C. pseudotuberculosis* (Preisz-Nocard bacillus) causes pseudotuberculosis in sheep and suppurative lymphadenitis in horses. Human infection is very rare.
- ***C. minutissimum:*** It causes a localized infection of skin (axilla and groin), called as '*erythrasma*.' It is a lipophilic *Corynebacterium*, can be grown readily in media containing 20% fetal calf serum. On Wood's lamp examination, erythrasma lesions emit coral red color.
- ***C. tenuis:*** It has been associated with *Trichomycosis axillaris*, characterized by the formation of pigmented nodules around axillary and pubic hair shafts.
- ***C. jeikeium:*** It is lipophilic species, colonizes skin of hospitalized patients. It can cause bacteremia, endocarditis and meningitis, especially in immunocompromized hosts. It is usually multidrug resistant, responds only to vancomycin.
- ***C. urealyticum:*** It is skin commensal, rarely causes urinary tract infection (pyelonephritis) and alkaline encrusted cystitis (struvite stones in alkaline urine) in immunocompromized and renal transplanted patients.
- ***C. amycolatum:*** It differs from other corynebacteria as it lacks mycolic acid in the cell wall. It rarely causes human infections such as catheter related infection and surgical site infection.
- ***C. pseudodiphtheriticum:*** It is a known commensal in throat. However, in immunocompromized patients, it can cause exudative pharyngitis (may mimic respiratory diphtheria) and endocarditis. It can be easily differentiated biochemically as it is pyrazinamidase test positive, urease positive and does not ferment glucose.
- ***C. striatum:*** It is a commensal on human skin and pharynx and also in cattle, rarely infects man.
- ***C. parvum*** is frequently used as an immunomodulator.
- ***Arcanobacterium haemolyticum*** (formerly placed under *Corynebacterium*): It can cause pharyngitis and skin ulcers. It is β hemolytic, produces a positive reverse CAMP test.

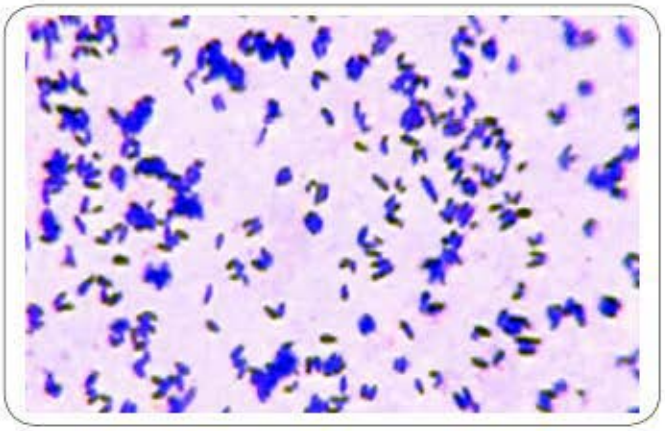

Fig. 24.6: Diphtheroids—Palisade arrangement of gram-positive bacilli

EXPECTED QUESTIONS

I. Essay:

1. A child aged 7 years with high grade fever, toxic, pain in the throat, inability to swallow attends the casualty. On examination, a white patch was found on the fauces. No history of immunization is available.
   a. Describe the pathogenesis of the condition?
   b. Write in detail about the laboratory diagnosis of this condition?
   c. Discuss the management of this condition?

II. Write short notes on:

1. DPT vaccines
2. Diphtheria toxin

III. Multiple Choice Questions (MCQs):

1. **Production of early metachromatic granules can be seen best in which of the following media:**
   a. Nutrient agar b. Chocolate agar
   c. Loeffler's serum slope d. Potassium tellurite agar
2. **Which of the following site is most commonly affected by *C. diphtheriae*?**
   a. Skin b. Conjunctiva
   c. Faucial d. Kidney
3. **Metachromatic granules of *Corynebacterium diphtheriae* can be stained by all of the following special stains except:**
   a. Neisser's stain b. Ziehl–Neelsen stain
   c. Albert's stain d. Ponder's stain

Answers

CHAPTER 25

Bacillus

Chapter Preview

- Bacillus anthracis
- Other bacillus species of human importance

Gram-positive spore forming bacilli belong to two genera:

1. *Bacillus:* They are obligate aerobes; having non bulging spores.
2. *Clostridium:* They are obligate anaerobes with bulging spores.

Bacillus species are obligate aerobic gram-positive spore forming rods. *B. anthracis* and *B. cereus* are the only pathogenic species; other members are ubiquitous, present in soil, dust, air and water, and are also frequently isolated as contaminants in bacteriological culture media. *Bacillus* species are generally motile (with peritrichous flagella) and non-capsulated except anthrax bacillus, which is non-motile and capsulated.

BACILLUS ANTHRACIS

Bacillus anthracis is the causative agent of an important zoonotic disease called **anthrax**. It also gained importance recently because of its ability to be used as biological weapon.

They are gram-positive, large rectangular rods (3–10 µm × 1–1.6 µm) arranged in chains, non-motile and capsulated bearing non-bulging oval spores.

Historical Importance

Considerable historical interest is attached to anthrax bacillus due to the following reasons:

- It was the first pathogenic bacterium seen under microscope (by Pollender, 1849).
- Anthrax was the first communicable disease shown to be transmitted by inoculation of infected blood.
- It was the first bacterium to be isolated in pure culture by Robert Koch (1876) and the Koch's postulates were made, based on *B. anthracis.*
- Anthrax vaccine was the first live attenuated bacterial vaccine prepared (by Louis Pasteur, 1881).

Virulence Factors and Pathogenesis

Pathogenesis of anthrax is due to two important virulence factors—anthrax toxin and capsule.

Anthrax Toxin

It is a tripartite toxin, consisting of three fragments.

1. **Edema factor:** It is the active fragment; acts as adenylyl cyclase and increases host cell cAMP (cyclic adenosine monophosphate). It is responsible for edema and other manifestations seen in anthrax.
2. **Protective factor:** It is the binding fragment that binds to the host cell receptors and facilitates the entry of other fragments into the host cells.
3. **Lethal factor:** It causes cell death, but the mechanism of action is not known.

These fragments are not toxic individually, but in combination, they produce local edema and generalized shock. Toxin synthesis is controlled by a plasmid (pX01). Loss of plasmid makes the strain avirulent. This was probably the basis of original anthrax vaccine prepared by Pasteur.

Anthrax Capsule

B. anthracis has a polypeptide capsule, made up of polyglutamate (in contrast to the polysaccharide capsule present in most of the other capsulated bacteria).

- Capsule is plasmid (pX02) coded
- It inhibits complement mediated phagocytosis.

Clinical Manifestations

Animal Anthrax

Anthrax is primarily a zoonotic disease. Herbivorous animals such as cattle, sheep and less often horses and pigs are affected more commonly than the carnivorous animals.

- Infection occurs in susceptible animals by ingestion of the spores present in the soil. Direct spread from animal to animal is rare.
- Anthrax in animals is presented as a fatal septicemia; however, localized cutaneous lesions may be produced rarely.
- Infected animals discharge large number of bacilli from the mouth, nose and rectum. These bacilli sporulate in soil and remain as the source of infection for man.

Human Anthrax

Transmission

Human beings acquire infection by:

- Cutaneous mode—by spores entering through the abraded skin; seen in people with occupational exposure to animals (most common mode).
- Inhalation of spores
- Ingestion of carcasses of animals dying of anthrax containing spores (manifested as bloody diarrhea).
- Indirectly through fomites (very rare).

Clinical Types

There are mainly three types of human anthrax.

1. Cutaneous anthrax (described in Table 25.1)
2. Pulmonary anthrax (described in Table 25.1)
3. Intestinal anthrax: It is rare; occurs due to ingestion of spores contaminated with meat of animals dying of anthrax. It is highly fatal and manifested as bloody diarrhea.

Agent of Bioterrorism

B. anthracis is one of the most common agent of bioterrorism. It has been widely used in various biological warfare, such as outbreaks in Sverdlovsk in 1979 and in United States in 2001.

- Pulmonary anthrax is the most common form to cause bioterrorism outbreaks.
- Transmission occurs via inhalation of anthrax spores from contaminated animal products.
- Though it has a high fatality, with prompt initiation of antibiotic therapy, survival is possible.

Epidemiology

Animal anthrax: It is primarily a disease of herbivorous animals. However, due to effective control measures, there has been a progressive global reduction in livestock anthrax cases over the past three decades.

- Both **enzootic** (endemic) and **epizootic** (epidemic) forms of the disease occur in India, especially in Andhra-Tamil nadu border, foci in Karnataka, and in West Bengal.
- Cycle in animals: Anthrax spores from the carcasses of dead animals remain viable in soil for decades. Grazing animals acquire the spores through abraded skin and the cycle continues.

Human anthrax: Incidence of human anthrax is highest in Africa, and central and southern Asia. Human anthrax cases may be of two types:

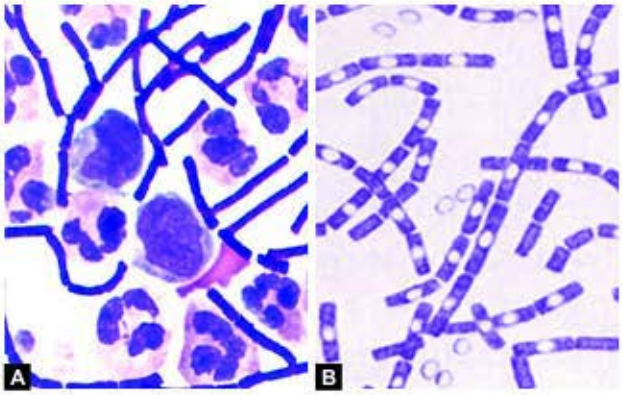
1. Non industrial cases: It result from agricultural exposure to animals.

TABLE 25.1: Differences between cutaneous anthrax and pulmonary anthrax

Features	Cutaneous anthrax	Pulmonary anthrax
Other name	**Hide porter's disease** (As it commonly occurs in dock workers carrying loads of hides and skins on their bare backs)	**Wool sorter's disease** (As it is seen in workers of wool factory, acquire infection by inhalation of dust from infected wool)
Transmission	Cutaneous exposure to spores (enter through abraded skin)	Inhalation of spores
Characterized by	**Malignant pustule (Fig. 25.1)** The lesion begins as a papule that evolves into a painless vesicle followed by the development of a coal-black, necrotic **eschar** surrounded by non-pitting indurated **edema** ▪ The name anthrax, which means coal, comes from the black color of the eschar ▪ However, it is a non-malignant condition.	**Hemorrhagic pneumonia** Bacilli spread by lymphatics or blood, leading to— ▪ Bacteremia ▪ Hemorrhagic mediastinitis ▪ Hemorrhagic meningitis
Occupational exposures	Dock worker, butcher, abattoir and farmer	Workers of wool factory
Occurrence	Most common (95%)	Rare
Prognosis	Self-limiting, rarely becomes fatal if untreated	Fatal
Bioterrorism	Rarely causes bioterrorism	Most common form to cause bioterrorism

Fig. 25.1: Malignant pustule

Source: Public Health Image Library, ID# 1934/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)



Figs 25.2A and B: Gram-stain of *B. anthracis*: **A.** Direct smear-shows gram-positive, large rectangular bacilli and pus cells; **B.** Culture smear-gram-positive bacilli (bamboo stick appearance)

Source: Wikipedia

2. Industrial cases: It result from infected animal products such as hides, hair, bristles and wools.

LABORATORY DIAGNOSIS — *Bacillus anthracis*

- **Specimen:** Pus, sputum, blood, CSF
- **Direct demonstration**
  - Gram-staining: Gram-positive, large rectangular bacilli
  - McFadyean's reaction: Shows amorphous purple capsule surrounding blue bacilli (polychrome methylene blue stain)
  - Direct IF: Detects capsular antigen
  - Ascoli's thermo precipitation test
- **Culture**
  - Nutrient agar: Medusa head appearance colonies
  - Blood agar: Dry wrinkled, non hemolytic colonies
  - Gelatin stab agar: Inverted fir tree appearance colonies
  - Selective media
    - Solid medium with penicillin: String of pearl colonies
    - PLET medium
- **Culture smear**
  - Gram-staining: Reveals gram-positive rods with bamboo stick appearance
  - Spore staining (Ashby's method and acid fast staining)
  - Lipid granules staining with Sudan black B
- Antibodies detection by ELISA
- Molecular diagnosis: PCR detecting specific genes
- Molecular typing: MLVA or AFLP

Laboratory Diagnosis

There is high risk of laboratory acquired infection of anthrax, hence utmost precautions should be taken and specimens should be processed in appropriate biological safety cabinets.

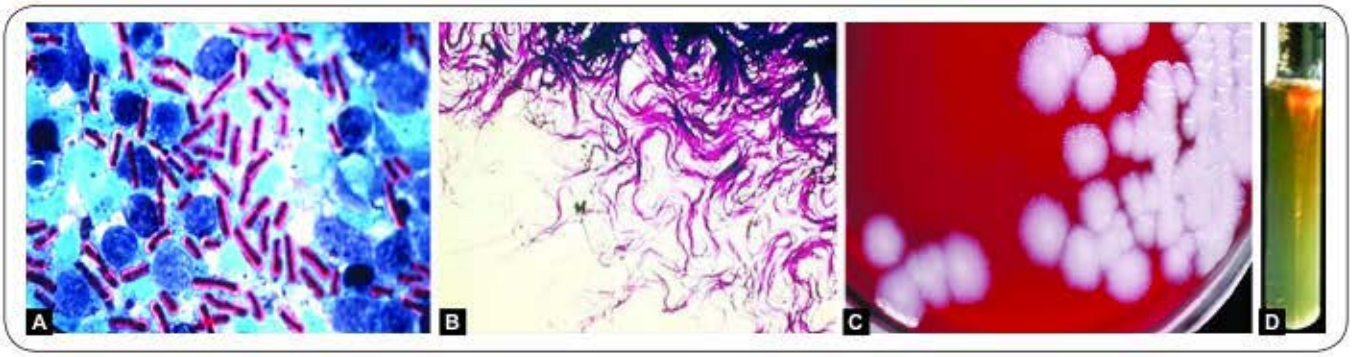
Specimen Collection

The specimens should be collected before starting antibiotic treatment. The useful specimens are:

- Pus or swab from malignant pustule
- Sputum in pulmonary anthrax
- Blood (in septicemia)
- CSF (in hemorrhagic meningitis)
- Gastric aspirate, feces or food (in intestinal anthrax)
- Ear lobes from dead animals

Direct Demonstration

- **Gram-staining:** Reveals gram-positive, large rectangular rods (3–10 µm × 1–1.6 µm). Spores are usually not seen in clinical samples (Fig. 25.2).
- **McFadyean's reaction:** Polypeptide capsule can be demonstrated by staining with Gurr's polychrome methylene blue stain for 30 seconds. Capsule appears as amorphous purple material surrounding blue bacilli (Fig. 25.3A). This is used for presumptive diagnosis of animal anthrax.
- **Direct immunofluorescence test (direct-IF):** It detects capsular and cell wall polypeptide antigens by using fluorescent tagged monoclonal antibodies. It is used for confirmation of the diagnosis during bioterrorism outbreaks.
- **Ascoli's thermoprecipitation test:** It is a ring precipitation test, done when sample is received in putrid form and bacilli are likely to be non-viable. Tissue samples are grounded in saline, boiled and filtered. This antigenic extract is layered over anthrax antiserum on a narrow capillary tube. A ring of precipitate appears at the junction of two liquids within 5 minutes.



Figs 25.3A to D: A. McFadyean's reaction—amorphous purple capsule surrounding blue bacilli (polychrome methylene blue stain); **B.** Medusa head colonies of *Bacillus anthracis* on nutrient agar (10x magnification); **C.** Non-hemolytic dry wrinkled colonies of *Bacillus anthracis* on blood agar; **D.** Gelatin stab agar-inverted fir tree appearance

Source: C. Public Health Image Library/ID#: 17097/Dr Todd Parker, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Culture

Bacillus anthracis is aerobic, non-fastidious, grows in ordinary media and has a wide temperature range (12–45°C) of growth. Sporulation is promoted at 25–30°C and in presence of unfavorable conditions such as distilled water, 2% NaCl, oxalate and oxygen.

Colony morphology of *B. anthracis* after 24 hours incubation of plates is as follows:

- **Nutrient agar:** Colonies are 2–3 mm in size, irregular, round, opaque, greyish white with a frosted glass appearance.
  Medusa head appearance: When colonies are viewed under low power microscope, the edge of the colony which is composed of long interlacing chains of bacilli, appears as locks of matted hair (Fig. 25.3B).
- **Blood agar:** It produces dry wrinkled, non-hemolytic colonies (Fig. 25.3C).
- **Gelatin stab agar:** Growth occurs as **inverted fir tree appearance** (due to liquefaction of gelatin which occurs maximum at the surface, and then slows down towards the bottom) (Fig. 25.3D)
- **Selective media:**
  - Solid medium with penicillin: Colonies have a **string** of **pearl appearance** look (due to cells becoming larger and spherical because of their weaker cell walls under the action of penicillin, and cells tend to occur in chain on surface of agar).
  - **PLET medium:** It consists of polymyxin, lysozyme, EDTA and thallous acetate added in heart infusion agar. It has been devised to isolate *B. anthracis* from mixtures of other spore bearing bacilli.

Culture Smear

- **Gram-staining:** Reveals **bamboo stick appearance**, i.e. long chain of gram-positive bacilli with non-bulging spores (appear as empty space) (Fig. 25.2B).
- **Spores:** They can be demonstrated by using special stains, such as hot malachite green (Ashby's method) or 0.25% sulphuric acid (spores are acid fast).
- **Lipid granules:** They can be demonstrated by staining with sudan black B (Burdon's method).

Serology

Antibodies appear in convalescent sera and can be detected by ELISA or immunodiffusion in gel method.

Molecular Diagnosis

PCR with specific primers can be used for further confirmation.

Molecular Typing: It is useful for epidemiological studies to trace the source of infection. Various methods available are as follows:

- MLVA (Multiple locus variable number of tandem repeat analysis)
- AFLP (Amplified fragment length polymorphisms).

Guidelines for Diagnosis of Anthrax during Bioterrorism Attacks (CDC, 2001)

In the wake of bioterrorism experience in USA (2001), the Centers for Disease Control and Prevention (CDC) has prepared guidelines for identification of *B. anthracis* during bioterrorism attacks:

- For presumptive identification of anthrax—any large gram-positive bacillus with morphology and cultural properties similar to anthrax bacillus.
- For initial confirmation, the tests done are:
  - Lysis by gamma phage
  - Direct immunofluorescence test (direct-IF)
- Further confirmation is done by PCR.

TREATMENT ***Bacillus anthracis***

Anthrax can be successfully treated if the disease is promptly recognized and appropriate therapy is initiated early.

- **Antibiotic regimen for treatment** consists of ciprofloxacin or doxycycline, plus clindamycin, and/or rifampin, for 60 days
- **Antibiotics for postexposure prophylaxis:**
  - Ciprofloxacin for 60 days ***plus***
  - Doxycycline for 60 days or Amoxicillin for 60 days (given if strain is penicillin sensitive)
- **Raxibacumab:** It is a monoclonal antibody that neutralizes anthrax toxin (protective antigen). It is intended for the prophylaxis and treatment of inhalational anthrax.

Prevention

The general control measures include:

- Disposal of animal carcasses by burning or by deep burial in lime pits.
- Decontamination (usually by autoclaving) of animal products.
- Protective clothing and gloves for handling potentially infectious materials.

Live Attenuated, Non-capsulated Spore Vaccine (Stern Vaccine)

It is extensively used in animals, remains protective for 1 year following single injection. However, it is not safe for human use.

Alum Precipitated Toxoid Vaccine

It is prepared from the protective antigen. Antibodies formed against protective antigen neutralize it and thus prevent attachment of toxin to the host cell.

- It is safe and effective for human use.
- Indication: It is given to persons occupationally exposed to anthrax infection.
- Schedule: It is given in three doses intramuscularly at first day, 6 weeks and 6 months and a booster dose after one year.

OTHER BACILLUS SPECIES OF HUMAN IMPORTANCE

Anthracoid Bacilli

Bacillus species other than the anthrax bacillus, are collectively called **anthracoid bacilli**.

- Except *B. cereus*, most of them are non-pathogenic and are common contaminants in laboratory cultures.
- They have a general resemblance to anthrax bacilli such as producing dry wrinkled colonies and in smear they appear as chains of spore-bearing gram-positive bacilli.
- However, they differ from anthrax bacilli in many ways (Table 25.2).

TABLE 25.2: Differences between *Bacillus anthracis* and anthracoid bacilli

Features	*Bacillus anthracis*	Anthracoid bacilli
Motility	Non-motile	Motile
Capsule	Present	Absent
Bacilli	In long chain	In short chain
Under low power microscope	Medusa head colony seen	Not seen
Blood agar	No hemolysis	Hemolytic colony
Broth	Turbidity absent	Usually turbid
Salicin	Not fermented	Fermented
Gamma phage	Susceptible	Resistant
Gelatin stab agar	▪ Inverted fir tree appearance seen ▪ Gelatin liquefaction slow	▪ Not seen ▪ Rapid gelatin liquefaction
Solid medium with penicillin	String of pearls appearance	No growth
At 45°C	No growth	Usually grows
Virulence	Pathogenic	Mostly non-pathogenic

Bacillus cereus

It is a normal habitant of soil, also widely isolated from food items such as vegetables, milk, cereals, spices, meat and poultry. It is an important agent of food poisoning in man.

Clinical Manifestations

- **Food poisoning:** It produces two types of toxins—diarrheal toxin (causes diarrheal type of food poisoning) and emetic toxin (causes emetic type of food poisoning) (Table 25.3).
  - **Emetic toxin:** It is a heat stable preformed toxin, resembling *S. aureus* enterotoxin. It acts immediately on intestine so that the incubation period of food poisoning is short (1–6 hours).
  - **Diarrheal toxin:** Organism secretes this toxin only after entering into the intestine, hence the incubation period is longer (8–16 hours).
- **Ocular disease:** It causes severe keratitis and panophthalmitis following trauma to the eye that may lead to loss of vision.
- **Other conditions:** It rarely causes systemic infections, including endocarditis, meningitis, osteomyelitis, and pneumonia. The presence of a medical device or intravenous drug use predisposes to these infections.

TABLE 25.3: Differences between diarrheal type and emetic type of food poisoning of *Bacillus cereus*

Bacillus cereus	Diarrheal type	Emetic type
Incubation period	8–16 hours	1–5 hours
Toxin	Secreted in intestine (Similar to *C. perfringens* enterotoxin)	Preformed toxin (formed in diet, similar to *S. aureus* enterotoxin)
Heat	Heat labile	Heat stable
Food items contaminated	Meat, vegetables, dried beans, cereals	Rice (Chinese fried rice)
Clinical feature	Diarrhea, fever, abdominal cramps	Vomiting, abdominal cramps
Serotypes involved	2, 6, 8, 9, 10, 12	1, 3, 5

Laboratory Diagnosis

- *Bacillus cereus* can be isolated from feces by using selective media such as:
  - MYPA (mannitol, egg yolk, polymyxin, phenol red and agar)
  - PEMBA (polymyxin B, egg yolk, mannitol, bromothymol, blue agar)
- It is motile, non-capsulated and not susceptible to gamma phage.

TREATMENT — ***Bacillus cereus***

Bacillus cereus is susceptible to clindamycin, erythromycin, vancomycin, aminoglycosides and tetracycline. It is resistant to penicillin (by producing β-lactamase) and trimethoprim.

Bacillus thuringiensis

It is closely related to *B. cereus* and may occasionally produce food poisoning. It is also used as larvicidal agent for mosquito control.

Bacillus Used as Sterilization Control

- *B. stearothermophilus* and *B. subtilis* both are used as biological controls for autoclave and plasma sterilization.
- *B. pumilus* is used as biological control for ionizing radiation.
- *B. globigii* is used as biological control for ethylene oxide.

Industrial Use of *Bacillus subtilis*

B. subtilis is used in industries for various purposes.

- Used as cleaning agent (detergent).
- In paper and textile industries—it produces amylase that breaks down starch.
- Used for pollution treatment—by breaking down pollutants (bioremediation).
- In pesticide industry—it is used for protecting crops against fungi.
- In food industry—helps in fermentation.

EXPECTED QUESTIONS

I. Essay:

1. Alisha, a 30-year-old woman, was admitted into hospital after a prolonged fever, with chills and night sweats, chest discomfort with blood stained sputum, nausea, headache and a sore throat. After being hospitalized, the doctors performed a Gram-stain for sputum specimen and found gram-positive rod-shaped bacteria arranged in chains. Other test results showed that the bacterium was aerobic and spore bearing.
   a. What is the clinical diagnosis and causative agent?
   b. Describe pathogenesis and various forms of clinical presentation of this infection?
   c. Mention the laboratory investigations to confirm the diagnosis?

II. Write short notes on:

1. Malignant pustule
2. *B. cereus* food poisoning

III Multiple Choice Questions (MCQs):

1. **Gram-stain morphology of *Bacillus anthrax* is:**
   a. Tennis racket appearance
   b. Drum stick appearance
   c. Bamboo stick appearance
   d. Spectacle glass appearance
2. **A "Malignant pustule" is a term used for:**
   a. An infected malignant melanoma
   b. A carbuncle
   c. A rapidly spreading rodent ulcer
   d. Anthrax of the skin
3. **Incubation period for *B. cereus* food poisoning following consumption of contaminated fried rice:**
   a. 1–6 hours
   b. 8–16 hours
   c. 24 hours
   d. > 24 hours

Answers

1. c **2.** d **3.** a

CHAPTER 26
Anaerobes (Clostridium and Non-sporing Anaerobes)

Chapter Preview

- Clostridium
  - Clostridium perfringens
  - Clostridium tetani
  - Clostridium botulinum
  - Clostridium difficile
- Non-sporing anaerobes

Anaerobic bacteria do not have cytochrome system for oxygen metabolism and hence are unable to neutralize toxic oxygen metabolites. They can be classified as follows:

- **Obligate anaerobes:** They cannot grow in presence of oxygen as they completely lack superoxide dismutase and catalase enzymes and hence are susceptible to the lethal effects of oxygen.
- **Aerotolerant anaerobes:** They do not utilize oxygen for growth, but tolerate its presence. This is because they possess small amounts of superoxide dismutase and peroxidase (but lack catalase), which may neutralize the toxic oxygen radicals. Examples include some clostridia (*C. histolyticum*) as well as few non-sporing anaerobes, such as *Bacteroides.*

Anaerobes need special requirements to grow in culture such as:

- **Anaerobic condition:** This can be achieved by various methods such as:
  - McIntosh and Filde's anaerobic jar
  - GasPak system
  - Anoxomat system
  - Anaerobic glove box
  - Pre-reduced anaerobically sterilized (PRAS) media
- **Medium with low redox potential:** This can be achieved by adding to the media with reducing substances such as unsaturated fatty acid, ascorbic acid, glutathione, cysteine, glucose, sulphites and metallic iron.

Obligate anaerobes can be grouped into spore bearing (e.g. *Clostridium*) and non-sporing anaerobes (described later in this Chapter).

CLOSTRIDIUM

Clostridia are gram-positive bacilli, having bulging spores (in contrast to the genus *Bacillus* which has non bulging spores), and encompass more than 60 species.

- Clostridia are saprophytes found in soil, fresh water, marine water, decaying vegetation, animal matter and sewage; thus play a major role in recycling of organic matter.
- They are also harbored in intestine of vertebrates and invertebrates including human beings.
- However, few members may cause a variety of infections in humans such as:
  - *C. perfringens*—causes gas gangrene
  - *C. tetani*—causes tetanus
  - *C. botulinum*—causes botulism (food, wound and infant botulism)
  - *C. difficile*—causes pseudomembranous colitis.
- **Industrial importance:** Some clostridia such as *C. acetobutylicum* and *C. butyricum* are used to prepare chemicals such as acetone and butanol.
- They are motile (exhibit stately motility) except *C. perfringens, C. ramosum* and *C. tetani* serotype VI.
- They are noncapsulated except *C. perfringens* and *C. butyricum.*

Spore

In clostridia, the spores are wider than the vegetative bacteria giving rise to swollen or spindle-shaped appearance (*Clostridium* is named from the word 'Kloster' meaning spindle). Spore formation occurs in unfavorable conditions. Most of the clostridia bear a sub-terminal spores except (Fig. 26.1):

- *C. tetani*—produces spherical and terminal spore (drum stick appearance).
- *C. tertium*—produces oval and terminal spore (tennis racket appearance).
- *C. bifermentans*—produces central and oval spore.

Cultivation

Clostridia grow well in various anaerobic media, such as Robertson's cooked meat (RCM) broth or thioglycollate broth.

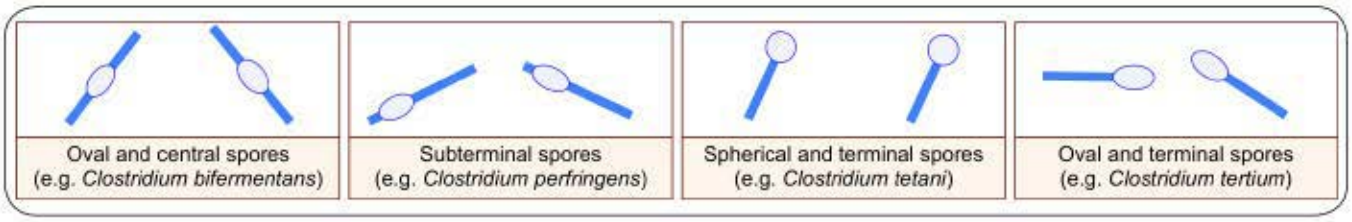


Fig. 26.1: Types of spores of various clostridia species

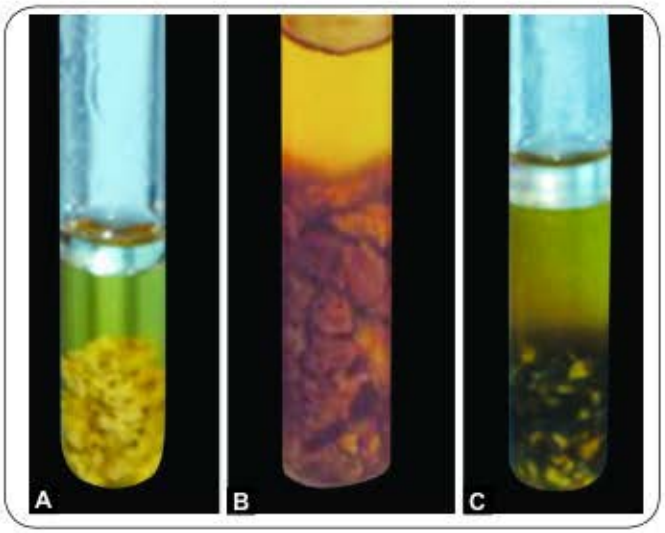

Figs 26.2A to C: Robertson cooked meat broth: **A.** Uninoculated; **B.** Pink and turbid (*C. perfringens*); **C.** Black and turbid *(C. tetani)*

Robertson's cooked meat (RCM) broth: It contains chopped meat particles (beef heart), which provide glutathione (a sulfhydryl group containing reducing substance) and unsaturated fatty acids, which take up oxygen and create lower redox potential and thus permit the growth of obligate anaerobes. Growth appears as turbidity in the medium which may be of two types (Fig. 26.2):

1. Proteolytic clostridia turn the meat black and produce foul odor, e.g. *C. tetani, C. botulinum* A, B and F.
2. Saccharolytic species turn the meat pink, e.g. *C. perfringens, C. difficile* and *C. botulinum* C, D and E.

CLOSTRIDIUM PERFRINGENS

C. perfringens (previously, *C. welchii*) is a commensal in the large intestine of human beings and animals. It is also found as saprophyte in soil, dust and air.

- It is capsulated, non-motile, gram-positive bacillus.
- It bears sub-terminal bulging spores; but does not produce spores in tissues or in culture media (especially the gas gangrene strains).
- It is invasive as well as toxigenic.

Virulence Factors

The virulence factors produced by *C. perfringens* can be grouped into different types (Table 26.1).

- Four major toxins—alpha (α), beta (β), epsilon (ε) and iota (ι).
- Eight minor toxins—gamma (γ), delta (δ), lambda (λ), kappa (κ), theta (θ), eta (η), mu (μ) and nu (υ).
- They also produce heat labile enterotoxin.
- Soluble substances are produced such as neuraminidase, histamine, bursting factor (produce muscle lesions) and circulating factor (inhibit phagocytosis).

Toxins of *C. perfringens* show varied biological activity (Table 26.1). Based on production of four major toxins *C. perfringens* can be classified into five types A to E as shown in Table 26.2.

TABLE 26.1: Biological activity of the toxins of *Clostridium perfringens*

Toxin	Biological activity
Major toxins	
Alpha (α)	Lethal, lecithinase (phospholipase C) Hemolytic Requires Ca^{+2} ion
Beta (β)	Lethal, necrotizing, trypsin labile
Epsilon (ε)	Lethal, permease, trypsin activatable
Iota (ι)	▪ Lethal, dermonecrotic ▪ Binary, has 2 fragments: Fragment A-ADP ribosylating Fragment B-Binding
Minor toxins	
Gamma (γ)	Mechanism of action not defined
Delta (δ)	Hemolysin
Lamda (λ)	Protease
Kappa (κ)	Collagenase and gelatinase
Theta (θ)	Hemolysin (O_2 labile) and cytolysin
Eta (η)	Mechanism of action not defined
Mu (μ)	Hyaluronidase
Nu (υ)	Deoxyribonuclease
Other toxins	
Neuraminidase	It makes RBCs panagglutinable, resulting in increase of blood viscosity and promoting capillary thrombosis
Enterotoxin	Enterotoxic and cytotoxic

TABLE 26.2: Classification of *Clostridium perfringens*

Types	Major toxin produced	Disease
A	Alpha	Gas gangrene, food poisoning
B	Alpha, beta and epsilon	Lamb dysentery
C	Alpha and beta	Enteritis necroticans in humans
D	Alpha and epsilon	Enterotoxemia and pulpy kidney disease in sheep
E	Alpha and iota	Possible pathogen of sheep and cattle

Clinical Manifestations

C. perfringens infections are mostly polymicrobial involving other clostridia species. Various manifestations include:

Clostridial Wound Infection

MacLennan has classified them as follows:

- **Simple wound contamination:** It involves the wound surface contamination, without invasion of underlying tissue, as occurs in absence of devitalized tissue.
- **Anaerobic cellulitis:** It involves the fascial plane with minimal toxin release, without muscle invasion.
- **Anaerobic myositis (gas gangrene):** Muscle invasion occurs, which leads to gas in the muscle compartment with abundant toxin release (described later).

Clostridial Enteric Infection

- **Food poisoning:** It is caused by *C. perfringens* type A enterotoxin (coded by *cpe* gene).
  - It occurs following consumption of improperly cooked contaminated meat. Spores being heat resistant survive and germinate later when the food is cooled.
  - Infective dose: About 10^8 viable vegetative bacilli producing enterotoxin is required to initiate the infection.
  - Enterotoxin acts by forming pores in the intestinal mucosal membrane.
  - Diagnosis—by detection of enterotoxin in feces by enzyme immunoassay.
- **Enteritis necroticans** (gas gangrene of the bowel): It is a life-threatening condition characterized by ischemic necrosis of the jejunum and gas in the tissue plane.
  - It is also known as **pigbel** in Papua New Guinea and **darmbrand** in Germany.
  - It is caused by *C. perfringens* type C strains, producing β toxin.
- **Necrotizing enterocolitis:** It resembles enteritis necroticans but is associated with *C. perfringens* type A and has been found in North America.
- **Gangrenous appendicitis.**

Other Clostridial Infections

- **Bacteremia:** *C. perfringens* followed by *C. tertium* and *C. septicum* are commonly associated with bacteremia.
- **Skin and soft-tissue infections**: *C. perfringens*, *C. histolyticum*, *C. septicum*, *C. novyi*, and *C. sordellii* cause necrotizing infections of the skin and soft tissues.
- Infection of the endometrium leading to toxic shock syndrome—can be associated with *C. sordellii*.
- Meningitis and brain abscess.
- Panophthalmitis (due to *C. sordellii* or *C. perfringens*).

Gas Gangrene

Definition (Oakley, 1954)

Gas gangrene is defined as a rapidly spreading, edematous myonecrosis, occurring in association with severely crushed wounds contaminated with pathogenic clostridia, particularly with *C. perfringens*. Previously, the disease was called **malignant edema** or **clostridial myonecrosis**.

Etiological agents

Gas gangrene is always polymicrobial and is caused by many clostridial species.

- **Established agents:** *C. perfringens* (most common, 60% of the total cases) and *C. novyi* and *C. septicum* (20–40%).
- **Probable agents:** They are less commonly implicated; e.g.—*C. histolyticum*, *C. sporogenes*, *C. fallax*, *C. bifermentans*, *C. sordellii*, *C. aerofoetidum* and *C. tertium*.

Pathogenesis

The development of gas gangrene requires:

- **Anaerobic environment:** Crushing injuries of muscles such as road traffic accidents (causing laceration of large or medium-sized arteries), open fractures of long bones or foreign bodies (bullet injuries) or devitalized tissues lead to interruption in the blood supply and tissue ischemia. Anoxic muscles start utilizing pyruvate anaerobically to produce lactic acid.
- **Contamination of wound** with clostridial spores present in the soil (during war or road traffic accident) or clothes.
- Rarely, spontaneous **non-traumatic gas gangrene** occurs via hematogenous seeding of normal muscle with bowel clostridia, occurs in people with gastrointestinal pathologies (e.g. colonic malignancy).

Virulence Factors Mediating Gas Gangrene

Toxins produced by *C. perfringens*

Once introduced *C. perfringens* proliferates locally and elaborates exotoxins, chiefly α toxin and θ toxin.

Contd...

Contd...

- α **toxin** is the principle virulence factor. It has both phospholipase C and sphingomyelinase activities.
  - It activates the platelet adhesion molecule ***gpIIbIIIa*** and neutrophil receptors ***CD11b/CD18***, leading to formation of aggregates of platelets and neutrophils in the blood vessels causing occlusion.
  - α toxin directly suppresses myocardial contractility leading to reduction in the cardiac output and results in profound hypotension.
- θ **toxin** causes marked vasodilation by activating mediators (e.g. prostacyclin, platelet-activating factor).

Toxins Produced by other Clostridia

- *C. septicum* produces four main toxins—α toxin (lethal, hemolytic, necrotizing activity), β toxin [deoxyribonuclease (DNase)], γ toxin (hyaluronidase), and septicolysin, protease and neuraminidase.
- *C. novyi* has four subtypes A–D. Type-A produces bacteriophage coded alpha-toxin, which commonly causes gas gangrene.

Clinical Manifestation of Gas Gangrene

The **incubation period** is variable. Depending upon the nature of injury, the amount of wound contamination and the type of clostridial species involved, the incubation period varies. For example:

- 10–48 hours for *C. perfringens*
- 2–3 days for *C. septicum*
- 5–6 days for *C. novyi*

Various manifesations include:

- Sudden onset of excruciating pain at the affected site.
- Rapid development of a foul-smelling thin serosanguineous discharge.
- Gas bubbles **(crepitus)** in the muscle planes (Fig. 26.3).

Fig. 26.3: Gas gangrene of the right leg showing swelling and discoloration of the right thigh with bullae, and palpable crepitus

Source: Wikipedia/Cases/Engelbert Schröpfer, Stephan Rauthe and Thomas Meyer (*with permission*)

- Brawny edema and induration.
- Such gangrenous tissues later may become liquefied and sloughed off.
- Shock and organ failure develop later.
- Associated with higher mortality rate (50%).

LABORATORY DIAGNOSIS — Gas gangrene

- **Specimen:** Necrotic tissues, muscle fragments and exudates from deeper parts of the wound
- **Direct microscopy:** Thick, stubby, boxcar-shaped gram-positive bacilli without spore are suggestive of *C. perfringens*
- **Culture:**
  - Media: Robertson cooked meat broth, egg yolk agar, etc.
  - Incubation: Anaerobically (by GasPak or Anoxomat, etc.)
- **Identification of *C. perfringens***
  - Target hemolysis (double zone hemolysis)
  - Nagler's reaction: Opalescence surrounding the streak line on egg yolk agar
  - Reverse CAMP test: Positive
  - Heat tolerance test: Positive
  - In litmus milk: Produces stormy clot reaction

Laboratory Diagnosis of Gas Gangrene

Based on the clinical diagnosis of gas gangrene, treatment should be started as early as possible. Laboratory diagnosis has role only for (1) confirmation of the clinical diagnosis, (2) species identification.

Specimen

- Ideal specimens are necrotic tissues, muscle fragments and exudates from deeper part of the wound where the infection appears to be more active.
- Blood culture may be positive for *C. perfringens* and *C. septicum*. However, *C. perfringens* bacteremia can occur even in the absence of gas gangrene.
- Swabs rubbed over the wound surface or soaked in exudates are not satisfactory.
- Specimens should be put into Robertson's cooked meat broth and transported immediately to the laboratory.

Direct Microscopy

Gram stained films provide clues about the species of clostridia present. Absence of neutrophils in the infected tissues is a characteristic feature.

- Thick, stubby, boxcar-shaped, gram-positive bacilli without spore—suggestive of *C. perfringens* (Fig. 26.4).
- Spore bearing gram-positive bacilli suggest other clostridia species.
  - Citron bodies (boat or leaf-shaped pleomorphic irregularly stained bacilli with spores)—suggest *C. septicum*.
  - Large rods with oval sub-terminal spores—suggest *C. novyi*.

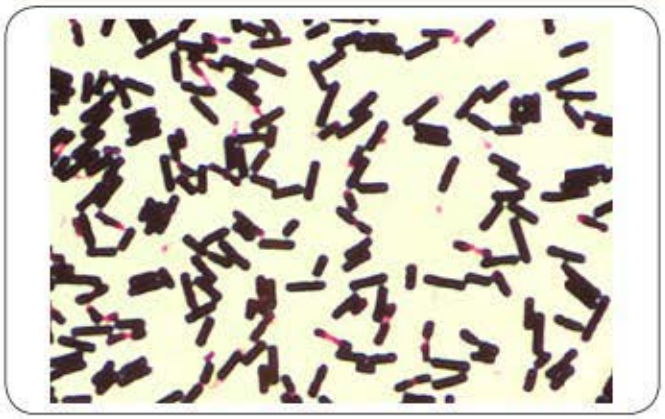

Fig. 26.4: *Clostridium perfringens* (Gram-stain)

Source: Public Health Image Library/ID# 11196, Don Stalons/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Identification

C. perfringens can be further identified by the following properties. Culture plates should be incubated anaerobically at 37°C for 2 days.

- **Target hemolysis** (double zone hemolysis, Fig. 26.5A): On blood agar, *C. perfringens* produce an inner narrow zone of complete hemolysis (due to θ toxin), surrounded by a much wider zone of incomplete hemolysis (due to the alpha toxin).
- **Nagler's reaction:** *C. perfringens* produces an opalescence surrounding the streak line on egg yolk agar or media containing 20% human serum (due to lecithinase activity of α toxin). Opalescence can be inhibited by incorporating anti-α toxin to the medium (Fig. 26.5B). The test is also positive for *C. bifermentans, C. baratti* and *C. sordellii* (all produce α toxin).
- **Reverse CAMP test:** *C. perfringens* is streaked over the center of blood agar plate and *Streptococcus agalactiae* is streaked perpendicular to it. Presence of enhanced zone of hemolysis (arrow-shaped) pointing towards *C. perfringens* indicates the test is positive (Fig. 26.5C).
- **Heat tolerance:** *C. perfringens* can grow when RCM broth is incubated at 45°C for 4–6 hours. This differentiates it from other organisms in the specimen.
- In litmus milk, *C. perfringens* produces "stormy clot reaction" due to fermentation of lactose producing acid and vigorous gas.
- Other clostridia species can be identified by various biochemical tests.

TREATMENT — Gas gangrene

- **Early surgical debridement** is the most crucial step in the management of gas gangrene. All devitalized tissues should be widely resected so as to remove conditions that produce anaerobic environment. Closure of wounds should be delayed for 5–6 days until the sites are free from infection.
- **Antibiotics:** Combination of penicillin and clindamycin is recommended for 10–14 days.
- **Hyperbaric oxygen:** It may kill the obligate anaerobic clostridia such as *C. perfringens*; however, it has no effect on aerotolerant clostridia (*C. septicum*).
- **Passive immunization** with anti-α-toxin antiserum.

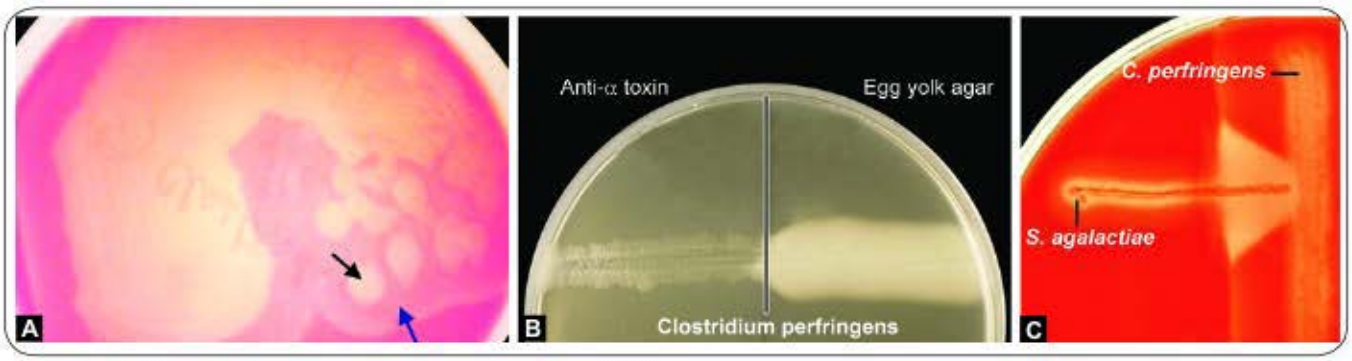
Prevention

Vaccination against α toxin is protective in experimental animals against gas gangrene, but has not been investigated in humans.

CLOSTRIDIUM TETANI

C. tetani is an obligate anaerobic, gram-positive bacillus with terminal round spore (drum stick appearance).

- It is the causative agent of 'tetanus'—an acute disease, manifested by skeletal muscle spasm and autonomic nervous system disturbance.
- Tetanus has been known since ancient time; however, its causative organism was isolated later by Kitasato (1889).



Figs 26.5A to C: **A.** Target hemolysis of *C. perfringens*-zone of incomplete hemolysis (blue arrow) and zone of complete hemolysis (black arrow); **B.** Nagler's reaction; **C.** Reverse CAMP test

- *C. tetani* is ubiquitous in nature, widely distributed in soil, hospital environment and intestine of man and animals.

Virulence Factors

C. tetani produces two exotoxins—tetanolysin and tetanospasmin.

1. **Tetanolysin:** It is a heat labile, oxygen labile hemolysin antigenically related to the oxygen labile hemolysins produced by *C. perfringens*, *S. pyogenes* and *S. pneumoniae*. It plays no role in the pathogenesis of tetanus.
2. **Tetanospasmin (or tetanus toxin):** It is a neurotoxin responsible for disease manifestations.
   - It is oxygen stable but heat labile.
   - Toxin is produced as a single 150 kDa polypeptide chain that is cleaved to produce heavy (100 kDa) and light (50 kDa) chains joined by a disulfide bond.
   - It is antigenic and is specifically neutralized by its antitoxin.
   - It gets toxoided spontaneously or by formaldehyde. The toxoid form is antigenic, but looses virulence property, hence, it is used for vaccine preparation.
   - Tetanus toxin is plasmid coded, its mechanism of action is given below.

Mechanism of Tetanus Toxin

Tetanus toxin binds to receptors (polysialogangliosides) present on motor nerve terminals which results in toxin internalization.

- Following internalization, tetanus toxin gets transported in retrograde way to the gamma-aminobutyric acid (GABA) and glycine producing inhibitory neuron terminals.
- The toxin prevents the presynaptic release of inhibitory neurotransmitters glycine and GABA, which leads to spastic muscle contraction.

Mode of Transmission

Tetanus bacilli enter through:

- Injury (superficial abrasions, punctured wounds, road traffic accidents).
- Surgery done without proper asepsis.
- Neonates—following abortion/delivery, due to unhygienic practices.
- Otitis media (otogenic tetanus).
- It is noninfectious—there is no person-to-person spread.

Clinical Manifestations

Incubation period is about 6–10 days. Shorter the incubation period, graver is the prognosis. Muscles of the face and jaw are often affected first (due to shorter distances for the toxin to reach the presynaptic terminals).

- First symptom—increase in the masseter tone leading to **trismus** or **lock jaw**, followed by muscle pain and stiffness, back pain, and difficulty in swallowing.
- In neonates, difficulty in feeding is the usual presentation.
- As the disease progresses, painful muscle spasm develops which may be:
  - Localized—involves the affected limb.
  - Generalized painful muscle spasm → leads to descending spastic paralysis.
- Hands, feet are spared and mentation is unimpaired. Deep tendon reflexes are exaggerated.
- Autonomic disturbance is maximal during the second week of severe tetanus-characterized by low or high blood pressure, tachycardia, intestinal stasis, sweating, increased tracheal secretions and acute renal failure.

Complications

Eventually, the following complications may be developed.

- **Risus sardonicus:** It is characterized by an abnormal, sustained spasm of the facial muscles that appears to produce grinning (Fig. 26.6A).
- **Opisthotonos position:** It is an abnormal posture of the body, occurs due to generalized spastic contraction of the extensor muscles (Fig. 26.6B).
- Respiratory muscles spasm—may cause airway obstruction.

Tetanus is more common in developing countries including India due to:

- Warm climate
- Rural area with fertile soil
- Unhygienic surgeries or deliveries.

However, the incidence has been reduced to a large extent due to widespread immunization of infants and pregnant mothers.

Laboratory Diagnosis

Treatment should be started immediately based on clinical diagnosis. Laboratory diagnosis provides supportive evidence for confirmation.

Specimen

Excised tissue bits from the necrotic depths of wounds are more reliable than wound swabs.

Gram Staining

- Gram staining reveals gram-positive bacilli with terminal and round spores (drum stick appearance) (Fig. 26.6C).
- However microscopy alone is unreliable as it cannot distinguish *C. tetani* from morphologically similar non-pathogenic clostridia like *C. tetanomorphum* and *C. sphenoides*.

Figs 26.6A to C: A. Lockjaw and the facial spasms (risus sardonicus); **B.** Patient with opisthotonos seen in tetanus; **C.** Gram-stained smear of *Clostridium tetani* showing round terminal spore bearing gram-positive *bacilli*

Source: A. Wikia/Hoidkempuhtust, B. Public Health Image Library, ID# 6373, C. ID# 12056/Dr Holdeman/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Culture

Culture is more reliable than microscopy.

- Robertson cooked meat broth—*C. tetani*, being proteolytic turns the meat particles black and produces foul odor.
- Blood agar with polymyxin B—these plates are incubated at 37°C for 24–48 hours under anaerobic condition. *C. tetani* produces characteristic **swarming growth**.

Toxigenicity Test

As pathogenesis of tetanus is toxin mediated, the association of the isolated organism can only be established when its toxin production is demonstrated. Toxigenicity can be detected by both *in vitro* and *in vivo* methods.

- ***In vitro* hemolysis inhibition test**—*C. tetani* produces hemolysis on blood agar which is inhibited by adding antitoxin. This test indicates the production of only tetanolysin but not tetanospasmin.
- ***In vivo* mouse inoculation test**—RCM broth with black turbid growth is injected into the root of the tail of a test mouse. The test animal develops stiffness which begins with the tail and progresses to involve the hind limbs on the inoculated side → the other limb → trunk →forelimbs. Death occurs within two days. This test indicates the production of tetanospasmin.

TREATMENT **Tetanus**

Passive immunization (tetanus immunoglobulin)
It is the treatment of choice for tetanus.

- **Two preparations are available:**

Contd...

TREATMENT **Tetanus**

1. HTIG (Human tetanus immunoglobulin), prepared in Serum Institute of India, Pune
2. ATS (Antitetanus serum, equine derived)

- **Dosage:** 250 IU of HTIG or 1500 IU of ATS is given as a single IM dose. Intrathecal route is more effective.
- **Duration of protection:** Effect of HTIG and ATS last for 30 days and 7–10 days respectively.
- HTIG is preferred over ATS as the latter is associated with side effects such as serum sickness and anaphylactoid reactions.

Combined Immunization
(Both active and passive immunization):

In non vaccinated person, it is ideal to immunize with first dose of tetanus toxoid (TT) vaccine in one arm along with administration of ATS or HTIG in another arm, followed by a complete course of TT vaccine, as per the schedule described later.

Antibiotics:
Antibiotics play only a minor role as they cannot neutralize the toxins which are already released.

- However, they are useful:
  - In early infection, before expression of the toxin (< 6 hours)
  - To prevent further release of toxin
- Metronidazole is the drug of choice. It is given 400 mg rectally or 500 mg IV every 6 hourly for 7 days.
- Penicillin can be given alternatively.

Other measures:

- Symptomatic treatment—antispasmodic (benzodiazepines) can be given.
- Entry wound should be identified, cleaned and debrided of necrotic material, so as to remove the anaerobic foci of infection.
- Patient should be isolated in a separate room as any noxious stimulus can aggravate the spasm.

Prevention

Active Immunization (Vaccine)

It is the most effective method of prophylaxis.

- **Tetanus toxoid (TT)** is commonly used for active immunization. It is available either as:
  - Monovalent vaccine—
    - Plain formal toxoid (or fluid toxoid)—toxoid is prepared by incubating toxin with formalin.
    - Adsorbed—formol toxoid is adsorbed on to alum.
  - Combined vaccine—DPT (consists of diphtheria toxoid, pertussis whole cell killed preparation and tetanus toxoid) (refer Chapter 24 for detail).
- **Primary immunization of children:** Tetanus toxoid is given under national immunization schedule of India. Total 'seven doses' are given; three doses of DPT at 6, 10 and 14 weeks of birth, followed by two booster doses of DPT at 16–24 weeks and 5 years followed by two additional doses of TT at 10 years and 16 years.
- **Adult immunization:** If primary immunization is not administered in childhood, then adults can be immunized with tetanus toxoid. Four doses of TT is given; 2 doses of TT at 1 month interval followed by 2 booster doses at 1 year and 6 years.
- **Site:** TT is given by deep intramuscular route at anterolateral aspect of thigh (children) and in deltoid (adults).
- **Protective titer:** Persons are said to be protected if tetanus antitoxin titre is ≥ 0.01 unit/mL.

Prevention of Tetanus after Injury

All types of wounds need surgical toilet followed by immunization which depends on the wound type and immunization status of the individual (Table 26.3).

TABLE 26.3: Recommendation for prevention of tetanus after injury

Immunity category	Simple wound*	Other wounds
Category A	Nothing required	Nothing required
Category B	Toxoid 1 dose	Toxoid 1 dose
Category C	Toxoid 1 dose	Toxoid 1 dose + HTIG
Category D	Toxoid complete dose	Toxoid complete dose + HTIG

Category A: Taken complete course of TT/booster within the past 5 years.
Category B: Taken complete course of TT/booster within the past >5 years to <10 years.
Category C: Taken complete course of TT/booster within the past >10 years.
Category D: Not taken complete course of TT/booster or immunity status is unknown.
*<6 hours, clean, non-penetrating, no/negligible tissue damage

Fig. 26.7: Neonatal tetanus (neonate displaying a bodily rigidity)
Source: Public Health Image Library, ID#6374/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Prevention of Neonatal Tetanus

Neonatal tetanus is defined by WHO as 'an illness occurring in a child who loses ability to suck and cry between day 3 and 28 of life and becomes rigid and has spasms'. It is also known as **"8th day disease"** as the symptoms usually start after 1 week of birth (Fig. 26.7).

- **Most common reason:** Unhygienic practices during deliveries such as infected umbilical stumps due to application of cow dung, rarely by circumcision or by ear piercing.
- **Seasonal:** Neonatal tetanus is seasonal-more common in July, August and September months.
- **Neonatal tetanus can be prevented by:**
  - Discouraging home deliveries and promoting hospital or attended deliveries.
  - Following aseptic **clean practices** are followed during deliveries—clean hand, clean surface, clean blade for cutting cord, clean cord tie, clean cord stump, clean towel and clean water.
  - TT (2 doses) are given to all pregnant women during 2nd trimester at 1 month gap.
- **Neonatal tetanus elimination is based on:**
  - Neonatal tetanus rate <0.1/1000 live births
  - TT coverage to pregnant women >90%
  - Attended deliveries >75%.

CLOSTRIDIUM BOTULINUM

Clostridium botulinum produces botulinum toxin and causes **botulism**, a rare disease manifested as various clinical syndromes ranging from food poisoning, wound infection to infant botulism.

- The term is derived from Latin word *botulus*, meaning sausage; as poorly cooked sausages were formerly associated with food poisoning.
- *C. botulinum* is anaerobic gram-positive bacillus with subterminal spore.
- It is ubiquitous in nature, widely distributed as saprophyte in soil, animal manure, vegetables and sea mud.

Pathogenesis

C. botulinum is non-invasive. Its pathogenesis is due to production of powerful neurotoxin 'botulinum toxin' (BT), probably the most toxic substance known to be lethal to mankind.

- BT is a 150 kDa zinc dependent protein consisting of a 100 kDa heavy chain and a 50 kDa light chain.
- **Serotype:** The light chain is serotype specific and can be typed into eight serotypes—A, B, C1, C2, D, E, F and G.
  - Serotypes A, B, E commonly cause human disease; most severe being serotype A.
  - All serotypes produce neurotoxin; except C2 which produces an enterotoxin.
  - BT types C and D are bacteriophage coded.
- BT differs from other exotoxins, as it is produced intracellularly, not secreted and appears outside only after autolysis of bacterial cell.
- Toxin is synthesized initially as a nontoxic protoxin. It requires trypsin or other proteolytic enzymes to convert it into active form.
- Mechanism of action of BT: It produces flaccid paralysis.

Mechanism of Action of Botulinum Toxin (BT)

After entry (either ingested, inhaled, or produced in a wound), botulinum toxin is transported via blood to peripheral cholinergic nerve terminals.

- The most common nerve terminal sites are neuromuscular junctions, postganglionic parasympathetic nerve endings, and peripheral ganglia. It does not affect the CNS.
- BT binds to acetylcholine receptors on the nerve terminals at neuromuscular junction, which results in blockage of release of the acetylcholine, leading to flaccid paralysis.

- **Therapeutic uses:** As BT produces flaccid paralysis it can be used therapeutically for the treatment of spasmodic conditions such as strabismus, blepharospasm and myoclonus.
- Botulinum toxin is also produced by other clostridia such as *C. butyricum* , *C. baratti* and *C. argentinense.*
- **Recovery:** Blocking of acetylcholine release is permanent, but the action is short lasting as the recovery occurs in 2–4 months, once the new terminal axons sprout.
- Spores do not produce toxins. Toxin production, therefore, requires spore germination, which occurs in anaerobic atmosphere. Spores do not normally germinate in adult intestine, however may germinate in the intestine of infants.

Clinical Manifestations

The manifestations of botulism are due to decreased acetylcholine in cranial nerve and parasympathetic nerve terminals. Common symptoms include:

- Diplopia, dysphasia, dysarthria
- Descending symmetric **flaccid paralysis** of voluntary muscles
- ↓Deep tendon reflexes
- Constipation
- There is no sensory or cognitive deficits
- Respiratory muscle paralysis, may lead to death.

Types of Botulism

- **Food borne botulism:** It results from consumption of foods contaminated with preformed botulinum toxin.
  - Most common source—home made canned food.
  - Most cases are sporadic; outbreaks are rare.
- **Wound botulism:** It results from contamination of wounds with *C. botulinum* spores. It presents like food borne botulism except for absence of gastrointestinal features.
- **Infant botulism:** It results from ingestion of contaminated food (usually **honey**) with spores of *C. botulinum* in children ≤1 year of age. Spores germinate releasing the toxin.
  - Manifestations include inability to suck and swallow, weakened voice, ptosis, floppy neck, and extreme weakness (hence called **floppy child syndrome**).
  - It is self limiting, managed by supportive care and assisted feeding.
  - Rarely, it progresses to generalized flaccidity, respiratory failure and sudden death.
- **Adult intestinal botulism:** Rarely, in patients with suppressed normal flora, the colonized clostridial spores may germinate producing toxin.
- **Iatrogenic botulism:** It results from injection of overdose of the toxin while used for therapeutic purpose.

Laboratory Diagnosis

Diagnosis of botulism includes isolation of the bacilli and demonstration of the toxin.

Isolation of the Bacilli

- Gram staining of smears made from suspected food or feces-reveals gram-positive, non-capsulated bacilli with subterminal, oval, bulging spores.
- It is motile by peritrichate flagella.
- **Isolation**—culture is done on blood agar or Robertson's cooked meat (RCM) broth.

  In RCM broth: Turbidity occurs with meat particles turning:
  - Black and production of foul odor—*C. botulinum* A, B, F (proteolytic).
  - Pink—*C. botulinum* C, D, E (saccharolytic).

  In blood agar: colonies are large, irregular, semi-transparent, hemolytic with fimbriated border.

- Growth on culture media may be confirmed by Gram staining and biochemical tests.
- Mere presence of bacilli in food or feces is of less significance. Toxin demonstration is more meaningful.
- Serotyping is done with type specific antisera.

Toxin Demonstration (Mouse Bioassay)

Toxins can be detected in the specimens (serum, stool, sterile water or saline enema, gastric aspirates, wound material) or in samples of ingested foods.

- Specimens are injected into mouse, that develops paralysis in 48 hours; which can be inhibited by prior administration of specific antitoxin.
- The sensitivity of the mouse bioassay varies inversely with the time elapsed between onset of symptoms and sample collection.

TREATMENT ***Clostridium botulinum***

- Meticulous intensive care support is needed (such as mechanical ventilation, if respiratory paralysis develops).
- **Botulinum antitoxin:** It should be administered immediately on clinical suspicion, without waiting for laboratory confirmation. Earlier the administration better is the cure rate because antitoxin can neutralize the unbound free toxin molecules. However, once toxin binds to nerve endings, antitoxin has no role.
- In wound botulism, suspected wounds and abscesses should be cleaned, debrided, and drained promptly.
- Antibiotics—though *C. botulinum* is susceptible to penicillin; the role of antibiotics has not been established.

CLOSTRIDIUM DIFFICILE

Clostridium difficile is an obligate anaerobic, gram-positive, spore-forming bacillus, responsible for a unique colonic disease—**pseudomembranous colitis** which occurs almost exclusively in association with prolonged antimicrobial use. It was so named due to unusual difficulties involved in the isolation of *C. difficile*.

Pathogenesis

Clostridium difficile infection is associated with the following risk factors.

- **Prolonged hospital stay:** Spores are found widely in nature, particularly in the hospitals and get colonized in colon of patients.
- **Prolonged antimicrobial use:** This can result in disruption of the normal colonic flora, which enhances the susceptibility to *C. difficile* infection.
  - Cephalosporins (e.g. ceftriaxone) are frequently responsible for this condition.
  - Other antibiotics, such as clindamycin, ampicillin and fluoroquinolones (ciprofloxacin) are also implicated in hospital outbreaks.
  - However, all antibiotics, including vancomycin and metronidazole (which are the drugs of choice in *C. difficile* infection) have been found to carry a risk of infection, if given for prolonged duration.
- **Toxin production:** Pathogenesis is toxin mediated. *C. difficile* may be harbored as a commensal in the intestine; however, only the toxigenic strains can cause pseudomembranous colitis.
  - It produces two powerful exotoxins—toxin A (enterotoxin) and toxin B (cytotoxin).
  - Both toxins A and B are secreted in the intestine → glycosylate the GTP binding proteins that regulate the cellular actin cytoskeleton → disruption of the cytoskeleton results in loss of cell shape, adherence, and disruption of epithelial cell barrier → leading to diarrhea, and pseudomembrane formation.
  - Infants do not develop symptomatic infection because they lack suitable mucosal toxin receptors which usually develop later in life.
- **Host immune response may determine the outcome of the infection.**
  - Persons developing strong IgG response to toxin A—become asymptomatic carriers.
  - Persons with inadequate IgG response to toxin A—develop disease.
- **Other risk factors:** Include older age, underlying illness, intestinal surgery, use of electronic rectal thermometers and antacid treatment.

Clinical Manifestations

- **Diarrhea** is the most common manifestation caused by *C. difficile*. Other manifestations include fever, abdominal pain and leukocytosis. Blood in stool is uncommon.
- **Pseudomembrane:** It is composed of necrotic leukocytes, fibrin, mucus, and cellular debris. It attaches to the underlying mucosa.
  - It appears as whitish-yellow plaque of size ranging from 1–2 mm size to large enough to spread over the entire colonic mucosa (Fig. 26.8A).
  - Relapse after treatment is common and seen in 15–30% of cases.

Laboratory Diagnosis

Laboratory diagnosis of *C. difficile* infection depends on isolation of the bacilli followed by toxigenicity testing.

- **Stool culture:** It is done under anaerobic condition at 37°C for 24–48 hours by using *C. difficile* specific selective media such as **CCFA** (cefoxitin cycloserine fructose agar) or **CCYA** (cefoxitin cycloserine egg yolk agar). Stool culture is highly sensitive and specific. However, since *C. difficile* can colonize the GIT, only isolation is not enough to establish the infection. Toxin demonstration is more meaningful.

- **Toxin demonstration:** Toxins can be detected by various methods.
  - Cell culture cytotoxin test on stool—it is highly specific but not as sensitive as stool culture; it is time consuming.
  - Enzyme immunoassay for toxin A or toxins A and B in stool—it is rapid, but not sensitive.
  - Enzyme immunoassay detecting common glutamate dehydrogenase antigen in stool found in toxigenic strains of *C. difficile*—it is more sensitive; however, less specific.
  - PCR detecting *C. difficile* toxin B gene in stool—it is highly specific and sensitive.
- **Colonoscopy:** It is highly specific if pseudomembranes are seen; however, the sensitivity is low, when compared with other tests (Fig. 26.8A).
- **Histopathology:** The histopathology of colonic pseudomembrane (obtained by colonoscopy) can be done by hematoxylin and eosin stain (Fig. 26.8B).

TREATMENT ***Clostridium difficile***

- **Initial episode, mild to moderate cases**—oral metronidazole is the drug of choice (500 mg thrice a day for 10–14 days).
- **Recurrent episodes or severe cases**—vancomycin is the drug of choice (500 mg, four times a day for 10–14 days)
- **Severe complicated or fulminant infection**—the combination of vancomycin (given via nasogastric tube and by retention enema) plus IV metronidazole has been recommended.

Prevention

- The transmission of *C. difficile* can be prevented by:
  - Improving hospital hygiene
  - Avoid using contaminated electronic thermometers
  - Use of hypochlorite (bleach) solution for decontamination of patient's rooms.
- Reducing the risk of infection if the organism is already transmitted: This can be done by restricting the use of certain antibiotics, such as clindamycin and cephalosporins for prolonged duration.

NON-SPORING ANAEROBES

Medically important non-sporing anaerobes can be classified into gram-positive and gram-negative groups. For the sake of convenience, even the anaerobic cocci and anaerobic gram-negative bacilli are discussed in this Chapter (Table 26.4).

Beside the list, there are several other anaerobes that occur in soil and water and may be of industrial and agricultural importance.

Non-sporing anaerobes are often a part of normal flora of mouth, GIT and genital tract of man (Table 26.5) and animals. Many of these bacteria have also been recognized as important cause of human infections.

TABLE 26.4: Classification of non-sporing anaerobes

Classification of non-sporing anaerobes	
Gram-positive cocci	**Gram-negative cocci**
▪ *Peptostreptococcus*	▪ *Veillonella*
▪ *Peptococcus*	**Gram-negative bacilli**
Gram-positive bacilli	▪ *Bacteroides*
▪ *Bifidobacterium*	▪ *Prevotella*
▪ *Eubacterium*	▪ *Porphyromonas*
▪ *Propionibacterium*	▪ *Fusobacterium*
▪ *Lactobacillus*	▪ *Leptotrichia*
▪ *Actinomyces*	**Spirochete**
▪ *Mobiluncus*	▪ *Treponema, Borrelia*

TABLE 26.5: Anaerobes as a part of normal flora

Anatomical site	Total bacteria/g or mL	Anaerobic/Aerobic ratio	Common anaerobic normal flora
Mouth			
Saliva	10^8–10^9	1:1	Anaerobic cocci
Tooth surface	10^{10}–10^{11}	1:1	*Actinomyces* *Fusobacterium*
Gingiva	10^{11}–10^{12}	10^3:1	*Bifidobacterium* *Prevotella* Spirochetes
Gastrointestinal tract (GIT)			
Stomach	0–10^5	1:1	*Lactobacillus*
Jejunum/ileum	10^4–10^7	1:1	Anaerobic cocci *Bacteroides fragilis*
Terminal ileum and colon	10^{11}–10^{12}	10^3:1	*Fusobacterium* *Bifidobacterium* *Prevotella*
Female genital tract			
Vagina	10^7–10^9	10:1	Anaerobic cocci *Lactobacillus* *Prevotella* *Bifidobacterium*
Skin			
Skin		3:2	*Propionibacterium*

Beneficial Role of Commensal Non-sporing Anaerobes

Being a part of normal flora, they modulate various physiological functions of human beings.

- They compete with the pathogenic bacteria through depletion of nutrients and production of enzymes and toxic metabolites.
- They modulate host's intestinal innate immune response.
- *Bacteroides* ferments carbohydrates and produce volatile fatty acids that are used by the host as an energy source.
- They are responsible for the production of vitamin K and bile acids in the intestine.
- Polysaccharide A of *Bacteroides fragilis* influences the normal development and function of immune system and protects against inflammatory bowel disease.
- Lactobacilli maintain the vaginal acidic pH which prevents colonization of pathogens.

Non-sporing Anaerobes Causing Disease

- Anaerobic infections occur when the harmonious relationship between the host and the bacteria is disrupted.
- Disruption of anatomical barrier (skin and mucosal barrier) by surgery, trauma, tumor, ischemia, or necrosis (all of which can reduce local tissue redox potentials) allow the penetration of many anaerobes, resulting in mixed infection.

INFECTIONS PRODUCED BY NON-SPORING ANAEROBES

Anaerobic Cocci

The anaerobic cocci occur as normal flora of skin, mouth, intestine and vagina.

- ***Peptococcus:*** It has one species, *P. niger*, which occurs as gram-positive cocci distributed singly or in pair or in clusters (but never in chain). It produces black color colonies on blood agar and also produces H_2S.
- ***Peptostreptococcus:*** It occurs as gram-positive cocci in pair or chains. It has many species which can be differentiated by various biochemical tests, susceptibility to antibiotics, such as SPS (sodium polyanethol sulfonate) and kanamycin and by fermentation of various sugars. Both *Peptococcus* and *Peptostreptococcus* are normal flora of skin, mouth, intestine and vagina. However, they are recovered from various clinical infections such as puerperal sepsis, skin and soft tissue infections and brain abscess (Table 26.6).
- **Veillonellae** are small gram-negative cocci, occurring in pairs or short chains. They are usually nonpathogenic.

Gram-positive Non-sporing Anaerobic Bacilli

- ***Bifidobacterium* species:** They are non-motile, pleomorphic bacilli that frequently exhibit branching. The name is derived from their typical appearance (bifid Y-shaped cells). They occur as normal flora in the mouth and gut and are mostly non pathogenic.
- ***Eubacterium* species:** They are commensals in mouth and intestine. They are rarely pathogenic (periodontitis).
- ***Propionibacterium* species:** They are related to corynebacteria and are usually labelled as anaerobic diphtheroids. They are skin commensals.
  - *P. acnes* is the most common species, which is a common contaminant in blood and CSF.
  - Its pathogenic role is uncertain.
- ***Lactobacillus* species:** They are non-motile gram-positive bacilli that frequently show bipolar and barred staining.
  - They are widely distributed as saprophytes and ferment materials such as milk and cheese.
  - They produce lactic acid from carbohydrates and grow best at pH of <5.

  They are part of normal flora of mouth, gut and vagina.
  - **In stomach:** Lactobacilli in the stomach (e.g. *L. acidophilus*) synthesise vitamins, such as biotin, vitamin B12 and vitamin K, which are useful to man.
  - **In the oral cavity:** It is postulated that lactobacilli may have a role in the pathogenesis of dental caries. Lactobacilli form acid by the fermentation of sucrose and other dietary carbohydrates which dissolve the mineral components of enamel and dentine.
  - **In vagina:** *Lactobacillus* species in adult vagina (known as Doderlein's bacilli) produce lactic acid that maintains the acidic pH of the adult vagina protecting from various infections. In prepubertal and postmenopausal vagina, lactobacilli are scanty which predispose to many infections.
- ***Actinomyces*:** They are branching filamentous anaerobic gram-positive bacilli. Detail is described in Chapter 28.
- ***Mobiluncus* species:** They are motile, curved, anaerobic gram-variable bacilli, isolated from the vagina in cases of *bacterial vaginosis*, along with *Gardnerella vaginalis*.

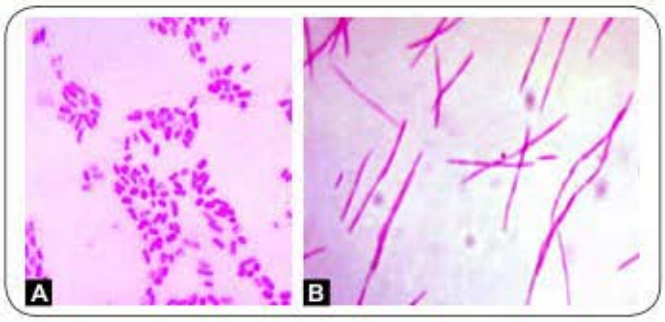
Gram-negative Non-sporing Anaerobic Bacilli

- ***Bacteroides fragilis:*** It is the most common commensal in the human intestine. At the same time, it is also probably the most frequent anaerobe isolated from the clinical specimens.
  - They are non-sporing, non motile, obligate anaerobes, very pleomorphic, appearing as slender rods or coccobacillary forms (Fig. 26.9A).
  - Virulence factors include:
    - Capsular polysaccharide
    - Lipopolysaccharide
    - Enterotoxin
  - It causes peritonitis following bowel injury and pelvic inflammatory disease (PID). It is also implicated in abdominal infections, brain abscesses and in empyema producing foul smelling pus. Enterotoxigenic strains can cause diarrhea.

TABLE 26.6: Anaerobic infections—an overview

Infections in various organs	Common anaerobe(s)
Mouth, head, and neck infections	
Dental caries (supra-gingival plaque)	*Lactobacilli*
Periodontal disease ▪ Gingivitis and ▪ Periodontitis	*Prevotella intermedia* *Porphyromonas gingivalis* *Treponema denticola*
Dental root canal infections	*Porphyromonas endodontalis*
Necrotizing ulcerative gingivitis ▪ Vincent's angina ▪ Trench mouth	*Leptotrichia buccalis*
Parapharyngeal space infections: ▪ Peritonsillar abscess (quinsy) ▪ Submandibular space infection (Ludwig's angina)	Mixed flora containing anaerobes and aerobes
Cervicofacial actinomycosis	*Actinomyces*
Sinusitis	*Prevotella, fusobacterium, Peptostreptococcus*
Chronic suppurative otitis media	*Bacteroides fragilis*
Central nervous system infections	
Brain abscess, epidural abscess, and subdural empyema	*Peptostreptococcus, Fusobacterium, Prevotella, Propionibacterium, Eubacterium, Veillonella, Actinomyces*
Pleuropulmonary infections	
Aspiration pneumonitis	Non-pigmented *Prevotella*
Necrotizing pneumonitis	*Peptostreptococcus*
Anaerobic lung abscesses	*Bacteroides*
Empyema	*Fusobacterium*
Abdominal infections	
Peritonitis and abscesses (following a breach in the intestinal mucosa)	Mixed colonic flora Most common—*Bacteroides fragilis*
Diarrhea	Enterotoxigenic *Bacteroides fragilis*
Pelvic and genitourinary infections	
Bartholin gland abscess, salpingitis, tubo-ovarian abscess, septic abortion, pyometra, endometritis and postoperative wound infection	*Bacteroides fragilis, Prevotella* (pigmented), Anaerobic cocci, *Clostridium* species
Puerperal sepsis	Anaerobic cocci
Bacterial vaginosis (also by *Gardnerella vaginalis*)	*Mobiluncus, Prevotella, Peptostreptococcus*
Skin and soft tissue infections	
Crepitant cellulitis, skin abscess, foot ulcers of diabetic patients	*Bacteroides, Peptostreptococcus, Clostridium*
Anaerobic bacterial synergistic gangrene (Meleney's gangrene), a rare infection of superficial fascia (also due to *Staphylococcus aureus*)	*Peptostreptococcus*
Necrotizing fasciitis (also due to *Streptococcus pyogenes*)	*Peptostreptococcus, Bacteroides*
Fournier gangrene (consists of cellulitis involving the scrotum, perineum and abdominal wall)	Mixed anaerobic organisms
Bone and joint infections	
Anaerobic infections of bone	*Actinomyces, Peptostreptococcus, Bacteroides, Fusobacterium*
Anaerobic septic arthritis	*Fusobacterium*
Cervical venous thrombophlebitis (Lemierre's syndrome)	*Fusobacterium necrophorum*
Bloodstream infection	
Bacteremia	*Bacteroides fragilis*
Endocarditis and pericarditis	*Bacteroides fragilis, Peptostreptococcus*

- ***Prevotella:*** Previously classified under *Bacteroides*, it differs from the former in being moderately saccharolytic. It has many species which can be grouped into—
  - Pigmented (e.g. *P. melaninogenica*)—
    - Produces hemin derived black or brown colored colonies.
    - Colonies appear characteristic red fluorescence when exposed to ultraviolet light.
    - It has been isolated from lung or liver abscess, mastoiditis, and lesions of intestine and mouth.
  - Nonpigmented—e.g. *P. denticola* and *P. buccalis.*



Figs 26.9A and B: Gram-stained smear of. **A.** *Bacteroides fragilis*; **B.** *Fusobacterium* species

Source: A. Public Health Image Library, ID# 3084/Dr VR Dowell, Jr./Centers for Disease Control and Prevention (CDC), Atlanta, B. Microbes Wiki/Jhoman (*with permission*)

- ***Porphyromonas:*** It differs from *Bacteroides* in being asaccharolytic and pigmented.
  - *P. gingivalis* is responsible for periodontal disease
  - *P. endodontalis* causes dental root canal infections.
- ***Fusobacterium* species:** They are long, thin spindle-shaped bacilli with pointed ends (Fig. 26.9B).
  - *F. nucleatum* is a normal inhabitant of the mouth and is found in oral infection and pleuropulmonary sepsis.
  - *F. necrophorum* is agent of Lemierre's syndrome (a form of thrombophlebitis).
- ***Leptotrichia buccalis*** (formerly called *Fusobacterium fusiforme)*: They are long, thin spindle-shaped bacilli with pointed ends.
  - They are part of the normal oral flora.
  - They are implicated in an acute necrotizing gingivostomatitis known as **Vincent's angina;** characterized by inflamed pharyngeal mucosa covered by a grayish membrane which peels easily, resembling diphtheria.

CLINICAL PRESENTATION OF ANAEROBIC INFECTIONS

Anaerobic infections are associated with various clinical clues, such as:

- Infections adjacent to mucosal surfaces that bear anaerobic flora
- Predisposing factors such as ischemia, tumor, penetrating trauma, foreign body, or perforated viscus
- Spreading gangrene involving skin, subcutaneous tissue, fascia, and muscle
- Foul smelling putrid pus
- Abscess formation
- Septic thrombophlebitis
- Toxemia and fever not marked
- Failure to respond to antibiotics that do not have significant anaerobic activity
- Organisms are seen under Gram stain, but fail to grow in routine aerobic culture
- Special features like:
  - Gas in specimen (gas gangrene)
  - Black pigment that fluoresce (*P. melaninogenica*)
  - Sulphur granules (*Actinomyces*)

LABORATORY DIAGNOSIS OF ANAEROBIC INFECTIONS

Specimens

All clinical specimens must be handled meticulously as brief exposure to oxygen may kill obligate anaerobes and result in failure to isolate them in the laboratory.

- Accepted specimens—tissue bits, necrotic materials, aspirated body fluids or pus in syringes.
- Unacceptable specimens—all swabs, sputum or voided urine.
- Specimens should be immediately put into RCM broth or other anaerobic transport media and brought to the laboratory as soon as possible.

Microscopy

All clinical specimens from suspected anaerobic infections should be Gram stained and examined for characteristic morphology.

Cultural Identification

- **Anaerobiosis:** Samples should be processed immediately under anaerobic condition which can be created by various methods as described earlier.
- **Culture:** Various culture media can be used for isolation of anaerobes, such as—
  - Anaerobic blood agar
  - Neomycin blood agar
  - Egg yolk agar
  - Phenylethyl agar (PEA)
  - BHIS agar—Brain-heart infusion agar added with supplements, such as vitamin K and hemin.
  - *Bacteroides* bile esculin agar (BBE agar)
- **Identification of anaerobes** is based on—
  - Biochemical tests
  - Susceptibility to antibiotic disks
  - Gas liquid chromatography.

TREATMENT **Anaerobic infections**

Common antibiotics given for anaerobic infections are:

- Metronidazole
- Carbapenems (imipenem)
- β-lactam/β-lactamase inhibitor combination (ampicillin/sulbactam)
- Chloramphenicol.

Choice of antibiotics depends on the site of infection, type of anaerobe involved and susceptibility to antibiotics. Antimicrobial resistance in anaerobic bacteria is an increasing problem.

EXPECTED QUESTIONS

I. Essays:

1. Rajesh, a 23-year-old male was admitted 5 days after a crush injury to his right leg following a road traffic accident. He had been treated by a local village quack. On examination, the wound which was bandged with a soiled gauze, appeared to be heavily contaminated with soil, the local muscles appeared to have been crushed, there was edema and pain at the site and crepitus was felt on palpation.
   a. What is the clinical condition? List the etiological agents responsible for this condition?
   b. Describe in detail the pathogenesis of this condition.
   c. Describe in detail the laboratory diagnosis of this condition?
2. 3–5 days following a bullet injury, a person developed trismus followed by muscle pain and stiffness, back pain, and difficulty in swallowing. As the disease progressed, painful muscle spasms developed which became generalized leading to a descending type of spastic paralysis. In the later stage, the patient assumed typical opisthotonus position of the body. Excised tissue bits from the necrotic depths of the wound revealed gram-positive bacilli with terminal and spherical spores.
   a. What is the diagnosis of this clinical condition?
   b. Describe in detail the pathogenesis and clinical manifestations of this condition?
   c. Describe in detail the laboratory diagnosis for confirming the etiological agent?
   d. Add a note on vaccination to prevent this condition.

II. Write short notes on:

1. Botulism
2. *Clostridium difficile*
3. Non-sporing anaerobes

III. Multiple Choice Questions (MCQs):

1. Characteristic of anaerobic bacteria is:
   a. Foul smelling discharge
   b. Fail to grow in aerobic media
   c. Gas in tissue
   d. All of the above

2. Principle toxin responsible for gas gangrene is:
   a. Alpha toxin
   b. Theta toxin
   c. Beta toxin
   d. Delta toxin

3. Site of action of tetanus toxin:
   a. Presynaptic terminal of spinal cord
   b. Postsynaptic terminal of spinal cord
   c. Neuromuscular junction
   d. Muscle fibers

4. The most effective way of preventing tetanus:
   a. Hyperbaric oxygen
   b. Antibiotics
   c. Tetanus toxoid
   d. Surgical debridement and toilet

5. Pseudomembranous colitis is caused by?
   a. *Clostridium perfringens*
   b. *Clostridium difficile*
   c. *Clostridium tetani*

CHAPTER 27

Mycobacteria

Chapter Preview

- Mycobacterium tuberculosis complex
- Nontuberculous mycobacteria
- Mycobacterium leprae

INTRODUCTION

Mycobacterium belongs to the family Mycobacteriaceae, order Actinomycetales.

All the species under the genus *Mycobacterium* should have the following minimum properties:

- **Acid fastness:** They resist decolorization by dilute mineral acids. Acid fastness is due to—(1) presence of high content of mycolic acids in the cell wall, and (2) integrity of the cell wall.
- **Guanine plus cytosine** (G+C) content of DNA of *Mycobacterium* is 61–71 mol %, the only exception being *M. leprae* with a G+C content of 54 to 57 mol %.

Mycobacteria are non-motile, non-sporing, non-capsulated, weakly gram-positive, straight or slightly curved rod-shaped bacteria, which are obligate aerobes (or microaerophilic). They sometimes show branching filamentous forms resembling fungal mycelium (*myces* meaning fungus, reflecting the mould-like pellicle formation on liquid media).

History

- Lepra bacillus was discovered by Armauer Hansen (1874), hence it is called **Hansen's bacilli**.
- Robert Koch (1882) isolated the tubercle bacillus and proved its causative role in tuberculosis as it satisfies the Koch's postulates.

Classification

Mycobacteria can be classified into:

- ***M. tuberculosis* complex:** It is responsible for tuberculosis in man.
- ***M. leprae*** (Hansen's bacilli): It causes leprosy
- **Nontuberculous mycobacteria (NTM):** These diverse group of mycobacteria are isolated from animals, soil and water and occasionally cause opportunistic human infection, e.g. *M. kansasii*.
- **Saprophytic mycobacteria** are isolated from soil, water and other environmental sources, e.g., *M. phlei* (from grass) and *M. smegmatis* (from smegma, a common contaminant in urine).

M. leprae and NTM have been described in detail later in this Chapter.

MYCOBACTERIUM TUBERCULOSIS COMPLEX

M. tuberculosis complex causes tuberculosis, which is one of the oldest disease of mankind, and is a major cause of death worldwide. It usually affects the lungs, although other organs are involved.

***M. tuberculosis* complex includes:**

- *M. tuberculosis* (human tubercle bacillus)
- *M. bovis* (bovine tubercle bacillus)
- *M. caprae* (closely related to *M. bovis*)
- *M. africanum* (isolated from few West African cases)
- *M. microti* ('vole' bacillus, rare and less virulent)
- *M. pinnipedii* (infects seals in the Southern hemisphere and recently isolated from humans)
- *M. canetti* (a rare isolate from East African cases, that produces unusual smooth colonies on solid media).

These species are so closely related to each other by antigenic and molecular analysis that, they are regarded by many authors as variants of a single species. However, they can be distinguished from each other by certain properties.

Among all, *M. tuberculosis* is the most common cause of tuberculosis in man. The subsequent discussion about *M. tuberculosis* complex in this Chapter will be restricted to *M. tuberculosis*.

Antigenic Structure

Antigens of *M. tuberculosis* are mainly of two types:

1. **Cell wall (insoluble) antigens:** The cell wall consists of several distinct layers (Fig. 27.1):
   - **Peptidoglycan layer:** It maintains the shape and rigidity of the cell.

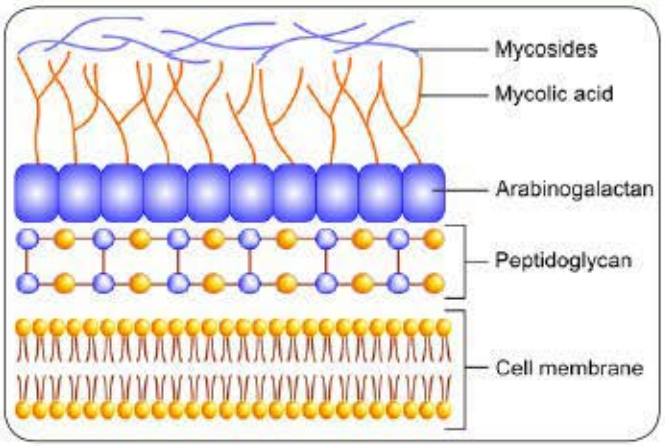

Fig. 27.1: Cell wall of *M. tuberculosis*

- **Arabinogalactan layer:** It facilitates the survival of *M. tuberculosis* within the macrophages.
- **Mycolic acid layer:** It is the principal constituent, made up of long chain fatty acids attached to arabinogalactan. It confers very low permeability to the cell wall and is responsible for **acid fastness** and also reduces the entry of most antibiotics.
- **Outermost layer:** It consists of lipids (mycocerosates and acylglycerols), glycolipids and mycosides (phenolic glycolipids).
- **Proteins** (e.g. porins, transport proteins): They are found throughout the various layers.
- **Plasma membrane:** This layer is present beneath the cell wall, into which various proteins, phosphatidylinositol mannosides, and lipoarabinomannan are inserted.

2. **Cytoplasmic (soluble) antigens:** These include antigen 5, antigen 6, antigen 60; and are used in serodiagnosis of tuberculosis.

Pathogenesis

Source of Infection

The source of infection of *M. tuberculosis* may be—(1) human (e.g. cases of pulmonary tuberculosis), (2) bovine source (e.g. consumption of unpasteurized infected milk).

Mode of Transmission

Inhalational mode: *M. tuberculosis* is mainly transmitted by inhalation of droplet nuclei, generated while coughing, sneezing, or speaking of infected patients. There may be as many as 3000 infectious nuclei per cough. The tiny dry droplets (<5–10 μm size) may remain suspended in the air for several hours and are easily inhaled.

Other modes of transmission are rare, such as:

- **Inoculation:** Transmission of infection through direct skin contact with an infected person is uncommon.
- **Ingestion:** Swallowing of sputum (in infants) or consumption of unpasteurized (infected) milk.

Risk Factors

The risk factors favoring the transmission of infection include:

- Sputum positive patients (sputum showing acid fast tubercle bacilli in microscopy) transmit more efficiently than sputum negative patients.
- Bacillary load: At least 10^4 bacilli/mL in sputum is required for an effective transmission.
- Adult patients with cavitary lesions in lung have more bacillary load in sputum and transmit efficiently.
- Overcrowding in poorly ventilated rooms.

Following infection, not all, but only a minor proportion of people develop progressing disease. They usually have the following endogenous risk factors such as:

- Low cell-mediated immunity: For example, HIV-infected people.
- Other comorbid conditions such as—post silicosis, post-transplantation (renal, cardiac), jejunoileal bypass, gastrectomy, chronic renal failure/hemodialysis, diabetes, IV drug abuse, smoking, etc.
- Age: Late adolescence and early adulthood periods are more prone.
- Sex: Risk is higher in women at 25–34 years of age, while at older ages, men have greater risk.

Sequence of Pathogenic Events

The sequence of pathogenic events that take place are as follows:

- **Droplet nuclei** containing tubercle bacilli from infectious patients are inhaled. Majority are trapped in the upper airways and expelled out by the ciliary action of the mucosal cells; only a fraction (usually <10%) of small droplets reach the alveoli.
- **Adhesion to macrophages:** Mycobacterial surface lipoarabinomannan (LAM) binds to complement receptors and mannose receptors present on the surface of macrophages. This leads to internalization of bacilli.
- **Phagocytosis by macrophages:** It is enhanced by complement (C3b) mediated opsonization of bacilli.
- **Survival inside the macrophages:** This is due to bacterial cell wall LAM which **impairs phagosome-lysosome fusion** by inhibiting increase in intracellular Ca^{2+} and phosphatidylinositol 3-phosphate.
- If the bacilli are successful in arresting phagolysosome fusion, then they happily replicate inside the macrophage. The macrophage eventually ruptures and releases its bacillary contents which infect other phagocytes and the cycle continues.

Host Immune Response

Cell-mediated Immune Response

Host's cell-mediated immune response to tubercle bacilli is critical to contain the infection.

- Macrophages present the mycobacterial antigens to T_H (T helper) cells and activate them into T_H1 and T_H2 subsets. T_H1 cells release cytokines such as IL-2 and IFN γ, which activate monocytes and macrophages.
- Thus, activation of T_H1 cells leads to development of two host responses: A macrophage-activating response and a tissue-damaging response. The balance between the two determines the outcome of the infection, as follows:

1. **Macrophage-activating response:**
   Majority of individuals show resistance to infection and are able to contain the bacilli.
   - IFN γ activates the resting alveolar macrophages into activated macrophages which are capable of killing and digesting the tubercle bacilli.
   - These activated macrophages aggregate around the center of the lesion and form characteristic granuloma called tubercles.

Tubercles: Tubercles are the essential pathological findings in tuberculosis. Formation of tubercle is a favorable sign. They are primarily of two types:

- **Hard tubercles:** Tubercles are initially hard, composed of a central zone containing activated macrophages (epithelioid and giant cells) and a peripheral zone of lymphocytes and fibroblasts.
- **Soft tubercles:** Later, the central part of the lesion undergoes caseous necrosis, and it contains necrotic material resembling soft cheese.

Growth of *M. tuberculosis* is inhibited within this necrotic environment because of low oxygen tension and low pH. Eventually, the lesion heals and calcifies. The viable bacilli may remain dormant within the macrophages or within the necrotic material for many years without causing further tissue destruction.

2. **Tissue-damaging response:**
   In a minority of cases, especially those associated with risk factors (as mentioned above), the macrophage-activating response is weak and the bacilli are more virulent.
   - Here the mycobacterial growth can be inhibited only by an intensified delayed hypersensitivity reaction (DTH) which leads to lung tissue destruction.
   - The caseous necrosis becomes liquefied, containing large numbers of bacilli which further spread by three ways:
     1. Direct draining into the airways, and then get discharged into the environment (while coughing and talking).
     2. Lymphatic spread and there by reseeding into the same or opposite lung → then disseminate to other organs.
     3. Hematogenous spread to various organs.

Contd...

Contd...

Humoral Immune Response

T_H2 cells derived cytokines such as IL-4, IL-5 activate B-cells to produce antibodies.

- *M. tuberculosis* being obligate intracellular organism, humoral immunity plays a minor role.
- However, the anti-LAM antibodies play a role in preventing dissemination of tuberculosis in children.

Koch's Phenomenon

Subcutaneous inoculation of virulent tubercle bacilli into guinea pigs may produce two types of reactions:

1. **Healthy guinea pig:** They do not show immediate local lesion, but after 10–14 days, a nodule is formed at the site of inoculation with enlarged caseous local lymph nodes, and subsequently leads to gradual death of the animal due to progressive tuberculosis involving several organs.
2. **Guinea pig that is previously exposed to tubercle bacilli:** Develops an induration at the site of inoculation in 2–3 days, which progresses into a shallow ulcer, and usually heals without systemic involvement.

Clinical Manifestations

Tuberculosis (TB) is classified as pulmonary and extrapulmonary forms.

Pulmonary Tuberculosis (PTB)

Pulmonary tuberculosis (PTB) accounts for 80% of all cases of Tuberculosis (TB). It can be further categorized into primary or post-primary (secondary) types (Table 27.1).

Extrapulmonary Tuberculosis (EPTB)

EPTB results from hematogenous dissemination of tubercle bacilli to various organs. Though EPTB constitutes about 15–20% of all cases of TB, in HIV-positive patients, the frequency is much higher accounting for 20–50% of all cases of tuberculosis.

Though, virtually all organ systems may be affected however, the sites commonly involved (in order of frequency) are:

- **Tuberculous lymphadenitis:** It is the most common form, accounting for 35% of all EPTB cases. The most common sites are posterior cervical and supraclavicular lymph nodes. It presents as painless swelling in the neck region without warmth or color change.
- **Pleural tuberculosis:** It accounts for 20% of all EPTB cases. It presents as pleural effusion.
- **Tuberculosis of the upper airways**—involving larynx, pharynx, and epiglottis.
- **Genitourinary tuberculosis:**
  - Renal tuberculosis

TABLE 27.1: Comparison of primary and secondary pulmonary tuberculosis

Features	Primary pulmonary tuberculosis	Postprimary/secondary pulmonary tuberculosis
Results due to	Initial exogenous infection with tubercle bacilli	▪ Exogenous reinfection ▪ Endogenous—reactivation of the latent primary lesion
Age group affected	Children	Adults
Parts of the lungs commonly affected	Sub pleural lesion affecting, upper part of the lower lobe and lower part of the upper lobe	Apical and posterior segments of the upper lobes (areas of high oxygen tension)
Lesions formed at the initial sites	Fibrotic nodular lesions are formed **(Ghon focus)**	Calcified nodules are formed (**Assmann** focus) Hematogenous seedling in the apex of lungs called **Simon's focus**
Lymph node	Ghon focus with associated hilar lymphadenopathy is common (called **primary complex**)	Lymph node involvement is unusual
Clinical feature	It may be asymptomatic or may present with fever, productive cough (with or without hemoptysis) and occasionally chest pain, night sweating, weight loss	Lesions undergoing necrosis and tissue destruction, leading to cavity formation. Symptoms are similar, but more pronounced.
Fate	In the majority of cases: ▪ Lesions heal spontaneously. ▪ Primary complex becomes calcified **(Ranke complex)** Rarely, in children with impaired immunity, progressive primary TB (develops and spreads by local invasion and by lymphatics)	In majority of cases: The necrotic material breaks into the airways, leading to: ▪ Bronchogenic spread to the same or opposite lung forms satellite lesions, which coalesce producing caseating pneumonia. ▪ Expectoration of bacteria-laden sputum. ▪ Hematogenous spread leading to seedling of bacilli in various parts of the body and granuloma formation. Rarely heals spontaneously.

  - Genital tuberculosis: In female patients, fallopian tubes and the endometrium are commonly involved causing infertility. In males, epididymis is the most common site.
- **Skeletal tuberculosis:** Weight-bearing joints, such as spine (Pott's disease or tuberculous spondylitis is most common), hips and knees are commonly affected. With advanced disease, collapse of vertebral bodies results in kyphosis (gibbus) and a paravertebral 'cold' abscess may also form.
- **Tuberculosis of CNS:** It occurs commonly in children. Tuberculous meningitis and tuberculoma are the common forms.
- **Gastrointestinal tuberculosis:** Terminal ileum and cecum are the most common sites involved. The route of spread may be due to swallowing of sputum with direct seeding, hematogenous spread, or ingestion of cow's milk contaminated with *M. bovis* (in developing countries).
- **Tuberculous pericarditis:** It occurs as direct extension from adjacent lymph nodes or following hematogenous spread. It occurs in elderly people, in countries with low TB prevalence.
- **Tuberculous skin lesions:**
  - ***Scrofuloderma:*** It is a skin condition caused by tuberculous involvement of the skin by direct extension, usually from underlying tuberculous lymphadenitis.
  - ***Lupus vulgaris:*** Apple jelly nodules are formed over the face in females.
- **Miliary or disseminated tuberculosis:** Hematogenous spread of tubercle bacilli results in the formation of yellowish 1–2 mm size granulomatous lesions resembling **millet seeds** (thus termed as miliary) in various organs. It is more common in HIV-infected people.

HIV-associated Tuberculosis

Tuberculosis is one of the most common opportunistic diseases among HIV-infected persons due to low CMI. Worldwide, TB occurs in 70–80% of HIV-infected individuals, EPTB being more common than PTB.

Epidemiology

About one-third of the current world population is infected asymptomatically with *M. tuberculosis*, of which 5–10% develop clinical disease during their lifetime.

- WHO has estimated that 8.8 million new cases of TB occurred worldwide in 2010, 95% of them in developing countries of Asia and Africa.
- The number of people dying from tuberculosis in 2010 was about 1.4 million.
- Patients with infectious pulmonary TB can infect 10–15 people in a year.

- India is the country with highest TB burden accounting for one-fourth (25%) of global TB cases.
  - The prevalence and incidence rates of tuberculosis in India were 256 and 185 cases per one lakh population in 2011.
  - In India, 2 deaths occur due to tuberculosis every three minutes and more than 1000 persons die every day and almost 0.37 million die every year.

LABORATORY DIAGNOSIS *Mycobacterium tuberculosis*

Diagnosis of Active Tuberculosis

Specimen collection

- In pulmonary TB—sputum (2 specimens—spot and early morning), gastric aspirate (in children)
- In EPTB—specimens vary depending on the site involved.

Digestion, decontamination and concentration of specimen:

- Petroff's method (4% NaOH)
- NALC (N-acetyl-L-cysteine) + 2% NaOH.

Direct microscopy by acid-fast staining:

- Ziehl Neelsen (ZN) technique—long slender, beaded, less uniformly stained red color acid fast bacilli
- Kinyoun's cold acid fast staining
- Auramine phenol technique.

Conventional culture media—takes 6–8 weeks

- Solid media, e.g. Lowenstein Jensen (LJ) medium—shows rough, tough and buff colored colonies
- Liquid media—middle brook 7H9 medium.

Automated culture methods—takes 2–3 weeks

MGIT, BACT/Alert and ESP system

Biochemical identification

- Niacin test positive
- Nitrate reduction test positive
- Pyrazinamidase test positive
- Resistant to TCH.

Serology

- Antigen detection—LAM and antigen-5 detection by ELLSA
- Antibody detection—not useful in endemic area.

Molecular methods

- PCR detecting IS6110 gene
- Other methods—line probe assay, TMA, SDA, NASBA, LCR.

Animal pathogenicity-using Guinea pig and rabbit

Diagnosis of latent tuberculosis:

By tuberculin test (e.g. Mantoux test) and interferon γ assay.

Laboratory Diagnosis

Laboratory diagnosis of active tuberculosis can be established by various methods described below. The diagnosis of latent tuberculosis is given later in the description.

Specimen Collection

In pulmonary tuberculosis (PTB), sputum is collected in a clean wide-mouthed container.

- ***Two sputum*** samples are recommended-spot sample (collected on the same day) and early morning sample (collected on the next day).
- Laryngeal swabs or bronchial washings may also be collected.
- In children, gastric aspirate may be collected as they tend to swallow sputum.

In extrapulmonary tuberculosis (EPTB), depending on the site involved various specimens are collected such as lymph node aspirate, pleural fluid, urine, synovial fluid, cerebrospinal fluid (CSF), pus from cold abscess or tissue biopsies.

Laboratory diagnosis of PTB is described below. The differences between the laboratory diagnosis of EPTB from that of PTB is followed thereafter.

Digestion, Decontamination of Specimen

Sputum and specimens from non-sterile sites need prior treatment for digestion (to liquefy the thick pus cells and homogenization), decontamination (to inhibit the normal flora) and concentration (to increase the yield). Processing should be carried out in class II biosafety cabinet. The following methods are available.

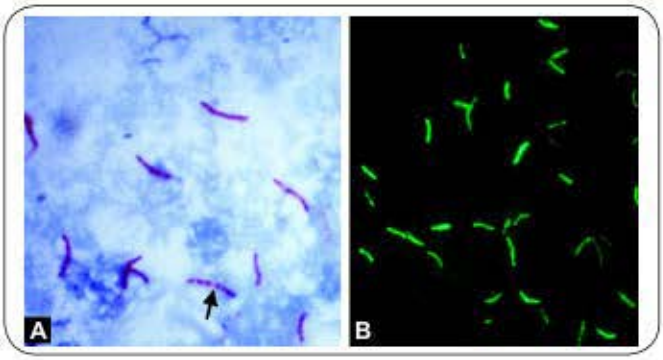
- **Petroff's method (4% NaOH):** Sputum is thoroughly mixed with equal volumes of 4% sodium hydroxide, centrifuged and the sediment is neutralized with 8% HCl.
- **NALC (N-acetyl-L-cysteine) + 2% NaOH:** This is superior to Petroff's method for isolation. NALC liquefies the sputum and NaOH kills the normal flora. This method is more compatible with automated culture systems.
- For smear microscopy, formalin or hypochlorite can also be used as mucolytic agent. However, they are not useful for culture or animal pathogenicity studies as the bacilli are killed.

Direct Microscopy by Acid-fast Staining

Ziehl–Neelsen (ZN) Technique

Smears (2 × 3 cm size) are prepared from thick mucopurulent part of sputum or with the sediment obtained after concentration.

- **Procedure:** (1) Smear is covered with primary stain, strong carbol fuchsin (basic fuchsin and phenol mixture) for 5 minutes. Intermittent heating of the slide is done till the fumes appear. Heating helps in better penetration of the stain; (2) Decolorization is done with 25% sulphuric acid for 3 minutes; (3) Counter staining is done with methylene blue for 1 min. Slide is examined under oil immersion objective.
- **Negative result:** At least 100 oil immersion fields should be examined before giving a negative report.
- **Positive result:** *M. tuberculosis* appears as long slender, beaded, less uniformly stained, red colored acid fast



Figs 27.2A and B: A. ZN staining of sputum smear showing long, slender and beaded acid–fast bacilli; **B.** Auramine phenol staining of sputum smear—Tubercle bacilli appear bright brilliant green against dark background

bacillus (AFB) (Fig 27.2A). *M. bovis* appears as short, stout, uniformly stained AFB (refer Table 2.3 of Chapter 2, for the list of other acid fast organisms).

- **Advantages:** Smear microscopy is rapid, easy to perform at peripheral laboratories and is cheaper.
- **Disadvantages:** (1) Smear microscopy is less sensitive than culture—as the detection limit of smear microscopy is 10,000 bacilli/mL of sputum; (2) It cannot determine the viability of bacilli.
- **Reporting:** Microscopy provides only presumptive diagnosis. If typical beaded appearance is seen, then it should be reported as 'acid-fast bacilli resembling *M. tuberculosis* are seen by smear microscopy by ZN stain'. It is difficult to differentiate *M. tuberculosis* from saprophytic mycobacteria present in tap water or even as commensals in clinical samples such as gastric aspirate, and urine.
- **Acid alcohol** (3% hydrochloric acid+ 95% ethyl alcohol): It can be used to differentiate *M. tuberculosis* (acid and alcohol fast) from *M. smegmatis* (acid fast but not alcohol fast) in urine sample.

RNTCP Guidelines for Grading of Sputum Smear

Revised National Tuberculosis Control Programme (RNCTP) of India has given guidelines for grading of sputum ZN smears (Table 27.2).

RNTCP grading is useful for:

- Monitoring the treatment response of the patients
- Assessing the severity of the disease
- Assessing the infectiousness of the patient: Higher the grade, more is the infectiousness. Smear-negative patients (<10,000 bacilli/mL of sputum) are less infectious.

Kinyoun's Cold Acid Fast Staining

It differs from ZN staining in that—(1) Heating is not required, (2) Phenol concentration in carbol fuchsin is increased, (3) Duration of carbol fuchsin staining is more.

TABLE 27.2: RNTCP guidelines for grading of sputum ZN smears

No. of bacilli seen	Grading	No. of OIF to be screened
>10/OIF	3+	20
1–10/OIF	2+	50
10–99/100 OIF	1+	100
1–9/100 OIF	Scanty	100
No AFB in 100 OIF	Nil	100

Abbreviations: OIF, oil immersion field; AFB, acid–fast bacilli

Auramine Phenol Technique

It is a fluorescent staining technique, uses auramine phenol as primary stain, acid alcohol as decolorizer and potassium permanganate as counter stain.

- The bacilli appear bright brilliant green against dark background (Fig. 27.2B).
- Smears are screened by using 20 X objective, hence can be screened faster (2 min for 100 fields).
- It is widely used by RNTCP in laboratories having higher sample load.

Conventional Culture Techniques

Culture Conditions

- **Incubating condition:** Tubercle bacilli are slow growing, due to long generation time (10–15 hours). Hence, inoculated culture media are incubated at 37°C, for 6–8 weeks.
- Media are incubated either aerobically for *M. tuberculosis* (which is an obligate aerobe) or microaerophilic condition (5% O_2) for *M. bovis*.
- *M. tuberculosis* grows luxuriantly (eugonic growth) whereas *M. bovis* grows sparsely (dysgonic growth).
- Addition of glycerol (0.5%) improves the growth of *M. tuberculosis* but not *M. bovis*.
- p-Nitrobenzoic acid (PNB) inhibits the growth of *M. tuberculosis* but not *M. bovis*.

Culture Media (Fig. 27.3)

Tubercle bacilli are highly fastidious and can grow only in enriched culture media, such as:

Solid media: Various solid media are:

Egg-based media: Examples include: Lowenstein-Jensen (LJ), Petragnani and Dorset egg media.

LJ medium: It is the most widely used and recommended by RNTCP and International Union against Tuberculosis (IUAT).

- It consists of coagulated hen's eggs, mineral salt solution, asparagine and malachite green (as a selective agent).
- **Colony appearance:** *M. tuberculosis* produces typical rough, tough and buff colored colonies (Fig. 27.3A). In contrast, *M. bovis* produces smooth, moist and white colored colonies which break up easily when touched.

Figs 27.3A to C: Culture medium for *M. tuberculosis*. **A.** Lowenstein-Jensen medium (rough, tough and buff colored colonies); **B.** BacT/ALERT bottle; **C.** BACTEC bottle

Other solid media include:

- Blood-based (Tarshis medium)
- Serum-based (Loeffler medium)
- Potato-based (Pawlowsky medium)
- Agar-based (Middlebrook 7H11 and 7H10): They are the preferred media for recovery of isoniazid resistant strains of *M. tuberculosis*.

Liquid media: They are not generally employed for routine culture, but are used for drug sensitivity testing and preparation of antigens and vaccines. Examples include Middlebrook 7H9, Dubos, Proskauer, Sula, and Sauton media. Virulent strains tend to form long serpentine cords in liquid media, while avirulent strains grow in a more dispersed manner.

Advantage of culture: (1) Culture is more sensitive than microscopy as it has a detection limit of just 10–100 viable bacilli. (2) Viability—bacteria growing on culture indicates that they are viable.

Disadvantage of culture: It is time consuming. Minimum 8 weeks of incubation is needed to give a negative report.

Automated Culture Methods

Several automated culture methods have been developed in last decade. They are rapidly gaining popularity. Many hospitals, now a days prefer to use these systems as they have many advantages over the conventional LJ culture. (see highlighted box).

Automated Culture Methods

They use liquid broth such as Middlebrook 7H9, supplemented with: (1) **OADC** enrichment growth media (Oleic acid, Albumin, Dextrose and Catalase); and (2) **PANTA** antibiotic mixture (Polymyxin B, amphotericin B, nalidixic acid, trimethoprim, and azlocillin).

- **Advantage:** (1) Detect growth faster (2–3 weeks), (2) Automated and continuous monitoring of the growth, (3) Less contamination issues.
- **Disadvantage:** They are expensive.

Principle used: There are many devices available commercially; each uses a different principle to detect the growth.

- **BACTEC MGIT** (**M**ycobacteria **g**rowth **i**ndicator **t**ube): Uses an oxygen sensitive fluorescent compound, dissolved in the broth. Initially, the large amount of dissolved oxygen quenches emissions from the compound and little fluorescence can be detected. Later, actively respiring microorganisms consume the oxygen and the absence of oxygen allows the fluorescence to be detected.
- **BacT/Alert:** Uses the principle of colorimetric detection of pH change in the medium, which occurs due to CO_2 liberated by the growth of *M. tuberculosis* (Fig. 27.3B).
- **ESP system:** Detects a change of pressure in the medium, which occurs due to the production of CO_2 by *M. tuberculosis*.
- **BACTEC 460:** It was the first semi automated system developed. As it was based on the use of radioisotopes to detect growth, hence not in use currently (Fig. 27.3C).

Biochemical Identification

Colony smears from LJ bottles are stained to demonstrate acid fast bacilli. Various biochemical tests are done to differentiate *M. tuberculosis* from other mycobateria.

Tests to Differentiate *M. tuberculosis* from *M. bovis* (Table 27.3)

- **Niacin test:** It is positive for *M. tuberculosis* and rarely for few strains of *M. simiae* and *M. cheloneii*. However, this is negative for *M. bovis*.
- **Nitrate reduction:** This test is positive for *M. tuberculosis* and negative for *M. bovis*.
- **Pyrazinamidase test:** *M. tuberculosis* produces pyrazinamidase, therefore, hydrolyses pyrazinamide. This test is negative for *M. bovis*.
- **TCH** (Thiophene caroboxylic acid hydrazide): *M. tuberculosis* is resistant to TCH, whereas *M. bovis* is sensitive.

Tests to Differentiate Tubercle Bacilli from NTM

- **Catalase test:** Tubercle bacilli (human and bovine) are weakly catalase positive where as nontuberculous mycobacteria (NTM) are strongly catalase positive. However, isoniazid resistant strains lose their catalase activities.

TABLE 27.3: Differences between *M. tuberculosis* and *M. bovis*

Property	*M. tuberculosis*	*M. bovis*
Acid-fast stain	Curved, long, beaded, less uniformly stained	Straight, short, stout, uniformly stained acid fast bacilli
LJ media	Rough, tough, buff colony	White, smooth, moist colony
Growth	Eugonic	Dysgonic
Glycerol	Helps in growth	No effect on growth
TCH	Resistant to TCH	Sensitive to TCH
Niacin test	Positive	Negative
Nitrate test	Positive	Negative
Rabbit pathogenicity	Not pathogenic	Pathogenic
Oxygen	Obligate aerobe	Microaerophilic
Both are pathogenic to guinea pig and human beings		

Abbreviation: TCH, Thiophene caroboxylic acid hydrazide

- **Arylsulfatase test:** Positive for rapid grower group of NTM, but negative for tubercle bacilli.
- **Tween 80 hydrolysis test:** Positive for certain NTM, such as *M. kansasii* and *M. marinum*. *M. tuberculosis* shows variable results.

Serology

- **Antigen detection:** Various formats such as capture ELISA, dip stick and latex agglutination tests are available for detection of specific *M. tuberculosis* antigens such as lipoarabinomannan and antigen-5 in sputum, urine and other samples. These tests are less popular because their sensitivity is low (40–50%).
- **Antibody detection** methods are no longer recommended in endemic areas because of cross reactivity with other environmental mycobacteria and variable antibody response against different epitopes.

Molecular Methods

Advantages: Molecular methods are extremely useful as they have several advantages such as:

- They take less time than culture
- They are more sensitive than culture, can detect as low as 1 bacillus/mL of specimens. This is very much useful for extrapulmonary samples which are usually paucibacillary in nature.
- They can also detect the drug resistance genes.
- Used for epidemiological typing of strains.

Molecular methods available are:

- **Nested PCR** (polymerase chain reaction) using IS6110 primer is widely used at present. Other genes which are targeted are—65 kDa and 38 kDa genes.
- **Other methods include:**
  - Probe based identification (Line probe assay)
  - Transcription mediated amplification (TMA)
  - Strand displacement amplification (SDA)
  - Nucleic acid sequence based amplification (NASBA)
  - Ligase chain reaction (LCR).

Animal Pathogenicity Testing

Guinea pig pathogenicity test: Both *M. tuberculosis* and *M. bovis* are pathogenic to guinea pigs. Intramuscular inoculation of the concentrated specimen produces progressive weight loss of the animal with positive tuberculin test (after 3–4 weeks) and death (after 6 weeks). Autopsy of the animal shows:

- Caseous lesion at the site of inoculation.
- Enlarged caseous inguinal lymph nodes.
- Tubercles may be seen in spleen, lungs, liver or peritoneum, but kidneys are unaffected.

Rabbit pathogenicity test: *M. bovis* is pathogenic, where as *M. tuberculosis* is not pathogenic to rabbit.

Diagnosis of EPTB

Diagnosis of EPTB differs from PTB in the following aspects:

- The EPTB specimens are paucibacillary, hence smear microscopy is less sensitive. Therefore, molecular methods are more useful in the diagnosis of EPTB.
- Specimens are free of normal flora; hence, initial decontamination and concentration methods are not required.
- Pleural fluid examination reveals elevated ADA (adenosine deaminase) and interferon (IFN)-γ levels.
- In renal tuberculosis: Urinary excretion of bacilli is intermittent; hence 3–6 consecutive early morning urine samples are collected, centrifuged and the sediment is used for processing. Acid alcohol is used as decolorizer.
- In tuberculous meningitis: CSF examination shows **cobweb coagulum** on standing, elevated CSF pressure, raised protein and chloride levels; whereas glucose levels is decreased.

Typing of Mycobacteria

Typing of mycobacteria is useful for epidemiological studies in determining the relatedness between various isolates in the communities.

- **Phenotypic methods** are less popular as they poorly discriminate between the strains. Examples include:

- Bacteriophage typing
- Bacteriocin typing

- **Genotypic methods** are more commonly used.
  - PCR-RFLP (Restriction fragment length polymorphism) is used to detect variations in IS6110 gene.
  - Spoligotyping: This is based on detecting the polymorphisms in DR locus (direct repeat) of *M. tuberculosis* genome. It is more useful in strains having no or few copies of IS6110 gene.
  - Pulse filed gel electrophoresis (PFGE)
  - DNA sequencing.

Diagnosis of Latent Tuberculosis

Latent tuberculosis is diagnosed by demonstration of delayed or type IV hypersensitivity reaction against the tubercle bacilli antigens. Two methods are available, (1) tuberculin test, (2) IFNγ release assay.

Tuberculin Test

Traditionally, the tuberculin test has been in use for diagnosis of latent TB for >100 years. It was discovered by Von Pirquet in 1907.

- **Antigens used in tuberculin test:**
  - **OT** (Old tuberculin antigen): It is a crude preparation of tubercle bacilli. It was described by Robert Koch, now rarely used.
  - **PPD** (Purified protein derivative antigen): It is an purified preparation of the active tuberculoprotein, prepared by Seibert in 1941(PPD-S) by growing *M. tuberculosis* in a semisynthetic medium.
    - WHO recommends a preparation of PPD, known as PPD-RT-23 with Tween 80.
    - PPD preparation from atypical mycobacteria such as PPD-B (Battey mycobacteria), PPD-Y (from *M. kansasii*) and scrofulin (from *M. scrofulaceum*) are also available.
- **Dosage:** It is expressed in tuberculin unit (TU). One TU is equal to 0.01 mL of OT or 0.00002 mg of PPD.
- **Procedure:**
  - **Mantoux test:** It is the most commonly employed method. 0.1 mL of PPD containing 1 TU is injected intradermally into flexor surface of forearm.
  - **Heaf and Tine multiple puncture tests:** Both the techniques are not in use as they are less precise in measurement of tuberculin reactivity.
- **Reading:** It is taken after 48–72 hours. At the site of inoculation, an induration surrounded by erythema is produced. If the width of the induration is:
  - ≥10 mm: Positive (tuberculin reactors)
  - 6–9 mm: Equivocal/doubtful reaction
  - <5 mm: Negative reaction
- **Interpretation of result:**
  - **Adults:** Positive tuberculin test in adults only indicates present or past exposure with tubercle bacilli but does not confirm the presence of active stage of the disease. Hence it is only used as an epidemiological marker.
    - Prevalence of tuberculosis is calculated by counting all tuberculin reactors in a community.
    - Incidence of tuberculosis is calculated by counting new converters to tuberculin test in a community.
  - **Children:** In children, positive test indicates active infection and used as **diagnostic marker**.
- **False-positive:** The test becomes positive after
  - BCG vaccination (after 8–14 weeks)
  - Nontuberculous mycobacteria infection
- **False-negative:** The test may become negative in various conditions such as—early or advanced TB, miliary TB, decreased immunity (HIV-infected people).
- **Two-step testing:** In adults, tuberculin reactivity slowly wanes with time and it may become negative after some years. In such as case, a repeat test 1–2 weeks after the first test exerts a booster effect and gives a strong positive reaction (>20 mm).

Interferon Gamma Release Assay (IGRA)

This uses highly specific *M. tuberculosis* antigens such as CFP10 (culture filtrate protein) and ESAT6 (early secreted antigenic target-6); both coded by RD1 genes.

- **Procedure:** In contrast to tuberculin test, it is an *in vitro* test. Sensitized T lymphocytes collected from suspected individuals, are exposed to ESAT-6/CFP-10 antigens, which leads to release of high level of IFNγ from the T lymphocytes. An ELISA formats is available commercially (QuantiFERON-TB Gold assay).
- **Advantage:** It is highly specific; there are no false-positive conditions.

TREATMENT — Tuberculosis

Anti-tubercular drugs can be classified into:

First line drugs:
- Isoniazid (H)
- Rifampin (R)
- Pyrazinamide (Z)
- Ethambutol (E)
- Streptomycin (S)

Second line drugs:
- Ethionamide
- Quinolones—ofloxacin, ciprofloxacin
- Aminoglycosides—kanamycin, capreomycin and amikacin
- Cycloserine
- Macrolides—clarithromycin

Treatment of tuberculosis aims to:
- Interrupt transmission by rendering patients non-infectious.
- Prevent morbidity and death by curing patients.
- Prevent the emergence of drug resistance.
- Prevent relapse.

Contd...

TABLE 27.4: Category-wise treatment regimen for tuberculosis (WHO guideline, 2010)

Category	Indications	Intensive phase	Continuation phase	Duration (months)
I	New patients ▪ New sputum smear—positive ▪ New sputum smear—negative ▪ New extrapulmonary	2 HRZE	4HR	6 months
II	Previously treated patients Sputum smear positive cases such as: ▪ Relapse ▪ Treatment failure ▪ Return after default Patient awaiting for DST* result	2 HRZES + 1 HRZE	5 HRE	8 months (for patients with low risk of MDR-TB)
		Empirical MDR** regimen	Empirical MDR regimen	18–24 months or till DST results (for patients with high risk of MDR-TB)

Abbreviations: *DST, drug susceptibility test, **MDR, multidrug-resistant, Relapse—A patient who was declared cured after treatment, returns smear positive; Treatment failure—A smear positive patient remains smear positive after 5 months of treatment; Return after default—A patient who returns smear positive after having left treatment for at least 2 months

Contd...

TREATMENT — Tuberculosis

To achieve the aims, the following strategies are followed:

- **Multidrug therapy:** Combination of more than one drug for rapid and effective killing of tubercle bacilli.
- **Short course chemotherapy** lasting for 6 months (or 8 months in previously treated cases).
- **Two phase chemotherapy:** The short course is divided into—
  - **Intensive phase** (initial phase, 2–3 months): Aims at aggressive treatment with 4 first line drugs that rapidly kill the bacilli making the patient smear negative, followed by:
  - **Continuation phase** (given for 4–5 months, with 2 or 3 first line drugs): Aims at killing the remaining dormant bacilli and prevents relapse.
- **DOTS strategy** (Directly Observed Treatment, Short course) is recommend by RNTCP and WHO. Here, the strategies used are:
  - The entire treatment course is supervised to improve the patient's compliance.
  - Treatment response is also monitored by periodic sputum smear microscopy.
- **Treatment regimens:** There are two treatment regimens, category I and II; both have different indications (Table 27.4).

Drug Susceptibility Testing (DST)

Both phenotypic and genotypic methods are available for carrying out DST for tubercle bacilli.

Phenotypic methods: Commonly used methods are:

- **Proportion method:** It is the gold standard method. The ratio of the number of colonies growing on drug containing medium to the number of colonies growing on drug free medium indicates the proportion of drug resistant bacilli present in the bacterial population.
- Automated systems, such as **BACTEC MGIT** are widely used these days. It mainly detects resistance to rifampicin.
- Other less popular phenotypic methods are:
  - Absolute concentration method
  - Resistance ratio method

Molecular methods: Several drug resistant genes (Table 27.5) can be detected by molecular methods such as:

- PCR based assays
- Probe based-Line probe assay
- DNA microarray

Resistance to Antitubercular Drugs

Drug resistance is the most worrisome aspect of management of tuberculosis. Development of drug resistance may occur due to:

- **Primary or pretreatment drug resistance:** It develops in a strain infecting a patient who has not previously been treated. It mostly occurs due to infection of an individual by a drug resistant strain. Primary resistance accounts for minority of cases.
- **Acquired resistance** (secondary or post treatment): It develops when the infective strain is initially sensitive, becomes resistant later. It is usually due to inappropriate or inadequate treatment. This is much more common than primary resistance.

Mechanism of Drug Resistance

Mechanism of resistance in tubercle bacilli is due to point mutation in the genome of *M. tuberculosis* which occurs at a rate of once in 10^8 cell divisions (Table 27.5).

TABLE 27.5: Drug resistance genes present in *M. tuberculosis*

Drugs	Drug-resistant genes
Isoniazid	Enoyl ACP reductase (inhA) Catalase-peroxidase (katG) Alkyl hydroperoxide reductase (AhpC)
Rifampicin	RNA polymerase subunit B (rpoB)
Pyrazinamide	Pyrazinamidase (pncA)
Ethambutol	Ribosomal protein subunit 12 (rpsL)
Streptomycin	Ribosomal protein subunit 12 (rpsL) 16s ribosomal RNA (rrs) Aminoglycoside phosphotransferase gene (strA)
Fluoroquinolones	DNA gyrase (gyr A and B)

Rationale of Using Multidrug Therapy

The most worrisome aspect of chemotherapy is development of drug resistance especially when monotherapy is used.

- This can be effectively checked by multiple drug therapy.
- Incidence of resistance to one drug is independent of that to another. Hence, the probability of a strain to be resistant to two drugs will be the product of the probabilities of resistance to each drug and thus drug resistance is much lower when multidrug regimen is used.

Failure to adhere to the multidrug regimen is the most important reason for development of resistance, which may be due to:

- Prolonged duration of regimen
- Poor compliance of the patient
- Development of toxicity to the drugs
- Improper supervision and follow up
- Irregular supply of drugs
- Incorrect prescription

Multidrug-resistant Tuberculosis (MDR-TB)

- **Definition:** MDR-TB is defined as resistance to isoniazid and rifampicin with or without resistance to other first line antitubercular drugs.
- **Epidemiology:**
  - As per WHO, 60% of total MDR-TB cases reside in **BRICS** countries-Brazil, Russia, India, China, South Africa, with India accounting for the maximum cases.
  - In India, MDR-TB accounts for 2.8% of all new TB cases and 12–17% of retreatment cases.
  - The actual number of MDR-TB may even be higher as the drug sensitivity testing facility is not available in many centres.
- **Treatment of MDR-TB** requires complex regimen of 2nd line drugs for longer course which are more toxic and expensive.
- **DOTS-Plus programme** is initiated by RNTCP (2000) to cover the diagnosis and treatment of MDR-TB cases. The updated treatment regimen is brought up in 2010 (revised DOTS Plus guideline). This standardized RNTCP regimen for MDR-TB is as follows (Table 27.6):
  - 6 drugs are given in the intensive phase for 6–9 months, followed by;
  - 4 drugs in continuation phase for 18 months.

TABLE 27.6: Standardized RNTCP regimen for MDR-TB (DOTS Plus guideline)

Intensive phase (for 6–9 months)	Continuation phase (for 18 months)
Kanamycin	Ofloxacin or levofloxacin
Ofloxacin or levofloxacin	Ethionamide
Ethionamide	Cycloserine
Cycloserine	Ethambutol
Pyrazinamide	
Ethambutol	

Extensively drug-resistant Tuberculosis (XDR-TB)

- **Definition:** They are MDR-TB cases which are also resistant to:
  - Fluoroquinolones (ofloxacin /levofloxacin) and
  - At least one injectable aminoglycosides (kanamycin, amikacin or capreomycin).
- **Epidemiology:** In USA, 3% of MDR-TB cases have been found to be XDR. The exact incidence of XDR-TB in India is not known. The MDT-TB treatment failure cases (2–6%) may be presumed to be XDR-TB cases.
- **Treatment** of XDR-TB is extremely difficult. XDR TB has a very rapidly progressing clinical course with high mortality.

Revised National Tuberculosis Control Programme (RNTCP)

The Govt. of India has launched this health programme in 1992, in collaboration with WHO and World Bank.

The main strategies of RNTCP are:

- Detecting >70% of estimated cases by quality sputum microscopy.
- Cure rate not less than 85%.
- Involvement of NGOs (Non-Govt. Organizations).
- Implementing DOTS (Directly Observed Treatment, Short course): A community based treatment and care of TB patients under supervision.
- Implementing DOTS Plus: For detection and treatment of MDR-TB.

Stop TB Strategy: WHO has launched Stop TB strategy in 2006 which aims at:

- By 2005: >70% of sputum smear positive cases will be diagnosed with > 85% cure rate.
- By 2015: Global burden of TB (prevalence and death rate) will be reduced by 50%.
- By 2050: Global incidence of TB will be <1 per million population per year.

Prophylaxis Against Tuberculosis

Bacillus Calmette Guerin Vaccine (BCG)

BCG vaccine was developed by Calmette and Guerin (1921). They attenuated the strain by serial sub culturing in glycerol bile potato medium for 230 times over a period of 13 years.

- **BCG strain:** Live-attenuated *M. bovis* was the strain originally used by Calmette and Guerin.
  - Though the same strain is used currently, due to different methods of maintenance in various vaccine laboratories, many substrains have evolved in past few decades.
  - In India, WHO recommended ***Danish 1331*** strain of BCG is used. It is prepared in Central BCG laboratory, Guindy, Chennai.

- **Types of vaccine:** BCG is available in two forms.
  - Liquid (fresh) form: It is less stable.
  - Lyophilized form (freeze-dried) form: It is more stable and is recommended for use.
- **Reconstitution of BCG:** Lyophilized form should be reconstituted before administration. This is done by using normal saline as diluent. Distilled water is never used as it is irritant. Once reconstituted; it has to be administered within 1 hour.
- **Administration of BCG**
  - Dose and strength: 0.1 mL containing 0.1 mg TU.
  - Alcohol should not used to wipe the skin.
  - Site: It is given above the insertion of left deltoid.
  - Route: It is administered by intradermal route by using a 26 gauge tuberculin syringe.
- **Phenomena after BCG:** If BCG is properly injected intradermally, then the following phenomena develops at the inoculation site-
  - After 2–3 weeks: Papule develops
  - 5–6 weeks: Shallow ulcer develops, which is covered with crust.
  - 6–12 weeks: Permanent tiny round scar (4–8 mm diameter) is formed.
  - 8–14 weeks: Mantoux test becomes positive.

  If overdose is given: The lesion or scar becomes larger and irregular in size.
- **Protection**
  - Efficacy: Many trials have shown that BCG has a variable efficacy of 0–80%.
  - Duration of immunity lasts only for 15–20 years.
  - Though BCG may not protect from the risk of tuberculosis infection, but it surely gives protection to infants and young children against development of complications such as tuberculous meningitis and disseminated tuberculosis.
- **Complications following BCG**
  - Most common complications include ulceration at the vaccination site and regional lymphadenitis.
  - Rarely, keloid or lupus lesion, and osteomyelitis may develop.
  - Very rarely, non-fatal meningitis, progressive tuberculosis and disseminated BCG infection ("BCGitis") are reported in people with low immunity.
- **Indications of BCG**
  - Direct BCG: BCG is directly given to newborn soon after the birth. This strategy is followed by most of the developing countries including India. If not given at birth it can be given later, maximum up to 2 years.
  - Indirect BCG: BCG is given after performing tuberculin test.
- **Contraindications to BCG include:**
  - HIV-positive child
  - Child borne to AFB positive mother
  - Child with low immunity
  - Generalized eczema
  - Pregnancy.
- **Other uses of BCG are:**
  - BCG induces non-specific stimulation of the immune system; thus provides some protection against certain diseases such as leprosy and leukemia.
  - BCG has been tried as an adjunctive therapy in malignancies, such as bladder carcinoma (Onco TICE strain of BCG).
  - BCG may be superior to PPD for tuberculin test, as reported by some workers.

Chemoprophylaxis

Treatment of selected high risk tuberculin reactors (i.e. people with latent tuberculosis) aims at preventing active disease. **Isoniazid (1 year)** or isoniazid and ethambutol for 9 months have been tried. However, chemoprophylaxis has several shortcomings such as—(1) it is expensive, (2) risk of developing tuberculosis is minimal in tuberculin reactors, and (3) side effects of the drugs.

Hence INH prophylaxis can be restricted to high-risk tuberculin reactors such as:

- Persons with low immunity including HIV-infected persons
- Persons with high risk medical conditions or fibrotic chest lesion
- Close contacts of tuberculosis.

NONTUBERCULOUS MYCOBACTERIA

Nontuberculous mycobacteria (NTM) were formerly called atypical mycobacteria or mycobacteria other than tubercle bacilli (MOTT).

NTM are diverse group of mycobacteria that are isolated from birds, animals, and from environmental sources, such as soil and water. They are opportunistic pathogens, occasionally associated with human infection. Man to man transmission is not known.

Saprophytic mycobacteria are isolated from soil, water and other environmental sources. They do not cause any disease in humans and are distinct from NTM. Examples include *M. phlei* (from grass), *M. smegmatis* (from smegma, a common contaminant in urine).

Classification of NTM

Non-tuberculous mycobacteria (NTM) have been classified (Table 27.7) into four groups by Runyon (1959), based on pigment production and rate of growth.

TABLE 27.7: Runyon's classification of nontuberculous mycobacteria

Runyon group	Property	Species
I. Photochromogens	Produce pigments only in light	*M. marinum, M. asiaticum, M. simiae, M. kansasii, M. genavense*
II. Scotochromogens	Produce pigments both in dark and light	*M. scrofulaceum, M. szulgai, M. gordonae M. celatum M. flavescens*
III. Non-photochromogens	Do not produce pigments	*M. avium-intracellulare* complex (MAC) *M. xenopi, M. ulcerans, M. paratuberculosis, M. malmoense*
IV. Rapid growers	Grow within one week	*M chelonae, M fortuitum, M. smegmatis, M. abscessus*

1. Photochromogens

They produce pigments only when the colonies are exposed to light. This group contains the following pathogens:

- ***M. marinum:*** It grows poorly or not at all at 37°C but grows well at 33°C. It is acquired from water sources (fish tanks, swimming) and enters through minor trauma. Various lesions produced are:
  - It typically causes papules or ulcers known as **swimming pool granuloma** or **fish tank granuloma**.
  - Tendonitis
  - Tender nodules: Spread in a sporotrichoid pattern similar to *Sporothrix schenckii*.
- ***M. asiaticum:*** It is rarely associated with pulmonary disease and bursitis.
- ***M. simiae:*** It was originally isolated from monkeys.
  - It gives a positive niacin test (so may be confused with *M. tuberculosis*).
  - It is principally isolated from pulmonary lesions.
- ***M. kansasii:*** It causes chronic pulmonary disease resembling tuberculosis.
  - Risk factors: Old persons with preexisting lung disease and with impaired immune responses.
  - It has been isolated from soil, water and milk.
  - It grows well at 37°C on LJ medium and produces a yellow-orange pigment.
- ***M. genavense:*** It grows very slowly and rarely causes infection in patients with advanced HIV.

2. Scotochromogens

They produce pigments (yellow, orange or red) even when cultures are incubated in dark, but intensity of color may increase on exposure to light.

- ***M. scrofulaceum:*** It causes scrofula (cervical lymphadenitis) in children.
- ***M. gordonae:*** It is often found as commensal in tap water and is a common contaminant of clinical specimens. It is rarely isolated from pulmonary specimens; however its pathogenic potential is doubtful.
- ***M. szulgai:*** It behaves as a scotochromogen at 37°C and photochromogen at 25°C. It may occasionally cause pulmonary disease and bursitis.
- ***M. celatum:*** It is a rare cause of pulmonary infection.

3. Nonphotochromogens

They do not produce any pigments. Examples include:

- ***M. avium-intracelluare* complex (MAC):** They comprise of two related organisms—*M. avium* (Battey bacillus, isolated from birds) and *M. intracelluare*.
  - They are opportunistic pathogens, especially in HIV-infected people with low CD4 T-cell count (<50/μL).
  - MAC can cause various manifestations: Lymphadenitis, respiratory infection and disseminated disease.
- ***M. xenopi:*** It has been isolated from hospital water supplies, and associated with nosocomial outbreaks.
  - It is found as a commensal, but rarely causes pulmonary disease especially in HIV-infected people.
  - Though classified as a non-photochromogen, *M. xenopi* may form yellow colored colonies similar to scotochromogens.
  - It was originally isolated from toads.
- ***M. ulcerans:*** It is a waterborne skin pathogen, found mainly in the tropics of Africa, Central South America and Southeast Asia.
  - It is the agent of **Buruli ulcer** (derived from Buruli district of Uganda where a large outbreak had occurred). Lesions are typically painless ulcers and nodules that become necrotic later.
  - It can also cause osteomyelitis and limb deformities.
  - **Exotoxin:** It produces mycolactone toxin which may be involved in the pathogenesis of the disease.
  - It has a narrow temperature range of 31°–34°C. It grows slowly, colonies appear in 4–8 weeks.
- ***M. malmoense:*** It can cause pulmonary disease and rarely lymphadenitis.
- ***M. paratuberculosis*** (Johne's bacillus): It mainly causes disease in cattle. It is associated with the pathogenesis of Crohn's disease, but this link has not been proved yet.
- Other rarely encountered non-photochromogens are—*M. shimoidei, M. terrae,* and *M. gastri.*

4. Rapid Growers

This group of NTM grow in culture within 1 week of incubation. Examples include:

- *M. fortuitum* and *M. chelonae:* They cause post-trauma injection abscess and catheter-related infections.
- *M. abscessus:* It can cause pulmonary infection.

TABLE 27.8: Clinical manifestations of nontuberculous mycobacteria (NTM)

Disease	Organisms
Pulmonary infection	*M. avium-intracellulare (MAC)* *M. kansasii, M. xenopi, M. malmoense, M. szulgai, M. abscessus*
Lymph node infection	*M. avium-intracellulare (MAC)* *M. scrofulaceum*—causes scrofula *M. malmoense*
Cutaneous infection	*M. marinum*—causes swimming pool or fish tank granuloma *M. ulcerans*—causes Buruli ulcer *M. abscessus* *M. fortuitum and M. chelonae*—cause injection abscess *M. avium-intracellulare (MAC)*
Disseminated infection	*M. avium-intracellulare (MAC)* *M. kansasii*

The following tests are done for rapid growers:

- Arylsulfatase test: Positive for all rapid growers.
- Growth on MacConkey agar: *M. fortuitum* grows on MacConkey agar in presence of 5% NaCl where as *M. chelonae* fails to grow.

The clinical manifestations of NTM are tabulated in Table 27.8.

Laboratory Diagnosis

- **Specimens:** Sputum, lymph node aspirate, pus or exudate, biopsy from skin lesions are the usual specimens, depending on the type of infection.
- **Microscopy by ZN staining:** Shows red acid fast bacilli which needs to be differentiated from *M. tuberculosis*.
- **Culture on LJ media:** Several species of NTM grow well on LJ medium, however a few grow sparsely.
- **Pigment production:** LJ media are incubated in dark and light separately for distinguishing between phtochromogens and scotochromogens.
- **Biochemical identification:** Species of NTM can be differentiated from each other and from *M. tuberculosis* complex by various biochemical reactions (Table 27.9)
- **Catalase test:** NTM are strongly catalase positive.
  - Semi quantitative catalase test: When H_2O_2 is added to a culture tube containing NTM colonies, bubbles appear and the column of bubbles exceeds 45 mm height.
  - Heat-stable catalase test: NTM are capable of producing positive reaction even after heating the culture at 68°C for 20 min.
- Other biochemical tests are mentioned in Table 27.9.

TREATMENT Nontuberculous mycobacterial disease

Just as in tuberculosis, NTM infections are treated with multidrug therapy and are associated with the emergence of drug resistance and relapse.

- *M. avium-intracellulare* complex (MAC) and *M. marinum* infections often require multidrug therapy with macrolide (clarithromycin or azithromycin), ethambutol, and a rifamycin (rifampin or rifabutin).
- *M. kansasii*: Similar to tuberculosis, it is also treated with isoniazid, rifampin and ethambutol for prolonged duration.

TABLE 27.9: Differences between *M. tuberculosis* complex and nontuberculous mycobacteria (NTM)

Property	*M. tuberculosis* complex	Nontuberculous mycobacteria (NTM)
Niacin test	*M. tuberculosis:* Positive *M. bovis:* Negative	Negative (except *M. simiae*)
Nitrate test		Variable (used for species identification of NTM)
Pyrazinamidase		Variable (used for species identification of NTM)
Tween 80 hydrolysis	*M. tuberculosis:* Variable *M. bovis:* Negative	Variable (used for species identification of NTM)
Optimum temperature for growth	37°C	Most species grow at 37°C except: *M. ulcerans* at 32°C, *M. marinum* at 30°C, *M. chelonae* at 28°C, *M. xenopi* at 42°C
Catalase test		
Semi quantitative catalase test	Bubbles rise <45 mm of the tube	Bubbles rise >45 mm of the tube (positive)
Heat stable catalase test	Negative	Most of the species are positive
Growth in presence of p-Nitrobenzoic acid (PNB)	*M. tuberculosis:* Does not grow	Grow
Arylsulfatase test	Negative	Only rapid growers give positive test
Growth on MacConkey agar (added with 5% NaCl)	No growth	Only *M. fortuitum* and *M. abscessus* grow

MYCOBACTERIUM LEPRAE

History

Mycobacterium leprae is the causative agent of leprosy; a disease of antiquity, having been recognized since long time such as:

- Vedic times in India (described as Kushta Roga in Sushruta Samhita, 600 BC)
- Biblical times in the Middle East
- Hippocrates in (460 BC).

The credit of discovery of lepra bacilli goes to **G. H. Armauer Hansen** (1873) in Norway. Although, *M. leprae* was the first bacterial pathogen of humans to be described, still it remains one of the least understood organisms probably because it is not cultivable. However, **Shepard** (1960) had done a breakthrough by multiplying the lepra bacilli in the footpads of mice kept at a low temperature (20°C).

Social stigma: Leprosy was once believed to be highly contagious disease.

- Due to fear, ignorance, superstitious beliefs and characteristic deformities and disfigurement produced in the patients, leprosy remained as a social stigma over many years.
- Patients were considered as 'unclean' and socially out casted.
- Today, with early diagnosis and effective treatment, patients can lead productive life in the community and the deformities can largely be prevented.

General Properties of Lepra Bacilli

- **Not cultivable:** *M. leprae* is not cultivable either in artificial culture media or in tissue culture; hence it does not follow the Koch's postulates.
  ICRC bacillus: In Indian Cancer Research Center (ICRC), Bombay (1962), an acid-fast bacillus was isolated from leprosy patients, employing human fetal spinal ganglion cell culture. It was shown to grow on LJ medium. However, its relation to the lepra bacillus is uncertain.
- **Animal models:** Lepra bacilli can be maintained in animals, such as **nine banded armadillo** (*Dasypus novemcinctus*) and **foot pad of mice** (kept at a low temperature, 20°C). It can produce natural disease in armadillo as well as other susceptible animals such as slender loris, Indian pangolin, chimpanzees and West African mangabey monkeys.
- **Intracellular:** Lepra bacilli are obligately intracellular and strict aerobe.
- **Less acid fast:** Compared to tubercle bacilli, they are less acid fast and can resist up to 5% sulfuric acid.
- **Appearance:** In smears made from skin lesions, they appear in groups, called **cigar-like bundles of bacilli** present inside lipid laden macrophages called **Virchow's lepra cells**.
- **Grow in cooler areas:** They have a tendency to grow in cooler areas of the body; hence, the clinical manifestations are largely confined to the skin, peripheral nerves, upper respiratory tract, anterior eyes, and testes.
- **Generation time:** Lepra bacillus has a long generation time of **12–13 days** as compared to 14 hours in tubercle bacillus and about 20 minutes for coliform bacilli.
- **Genome of *M. leprae*** has undergone reductive evolution over the time. Almost half of genes have become non-functional, many of those used to code for metabolic and respiratory pathways. This made the bacilli obligately intracellular and are dependent on host biochemical support.

Clinical Manifestations

Leprosy is a chronic granulomatous disease of humans, primarily involving cooler parts of the body but are capable of affecting any tissue or organs causing bony deformities and disfigurements in untreated cases.

Incubation period: Leprosy has a long incubation period, an average of 3–5 years (vary between 2 and 40 years).

- This can be explained due to the longer generation time of lepra bacilli.
- Lepromatous cases have longer incubation period than tuberculoid cases.

Classification of Leprosy

Leprosy can be classified into various categories based on clinical, bacteriological, immunological and histological status of the patients (Table 27.10). Following start of treatment or alteration of host immunity, the leprosy category of patients changes from one type to another type.

Leprosy is a bipolar disease. Under any classification scheme, lepromatous and tuberculoid cases are the two extreme poles of the disease (Table 27.11).

Lepromatous Leprosy (LL)

It is seen when the host resistance is low to lepra bacilli.

- **Multibacillary disease:** Large number of acid fast bacilli are found in large clumps (globi) inside the macrophages (lepra cells).
- **Skin lesions** are many, symmetrical with irregular margin. Lesions appear as superficial nodular lesions (lepromata) or plaques or xanthoma-like papules. Lesions on face produce **leonine facies** appearance. Loss of eye brow/lashes may occur late.

TABLE 27.10: Classification of leprosy

Ridley-Jopling classification (1966)	Madrid classification (1953)	Indian classification* (1981)
Lepromatous leprosy (LL)	Lepromatous type	Lepromatous type
Borderline Lepromatous leprosy (BL)	Borderline	Borderline
Borderline leprosy (BB)	Indeterminate type	Indeterminate type
Borderline Tuberculoid leprosy (BT)	Tuberculoid type	Pure neurotic type
Tuberculoid leprosy (TT)	—	Tuberculoid type

Note: There is another **clinical classification of leprosy** (two types—paucibacillary and multibacillary) available. This classification is used by the control programme for the treatment of leprosy patients (described later).

*Leprosy association of India

- **Nerve lesions:** The nerve involvement occurs very late in LL patients.
- **Host immunity:**
  - The CMI of the LL patient is grossly impaired. As a result the lepromin test and lymphocyte transformation test become negative.
  - In contrast, the humoral immune response: It is exaggerated in LL patients (described later).
  - **Spread:** Bacilli invade nasal mucosa and are shed in large numbers in nasal secretions. LL patients are most infectious. Later on, reticuloendothelial system, eyes, testes, kidneys and bones are also involved. Eventually, any organ can be involved except CNS and lungs. Bacteremia is common.
  - **Prognosis:** LL patients have a poor prognosis.

Tuberculoid Leprosy (TT)

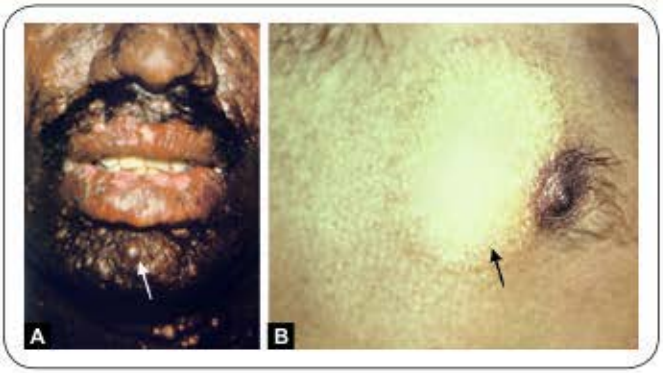
It is seen in patients showing a high degree of resistance to lepra bacilli.

- **Paucibacillary disease:** Bacilli are scanty in the lesions.

TABLE 27.11: Differences between lepromatous leprosy and tuberculoid leprosy

Characters	Lepromatous leprosy (LL)	Tuberculoid leprosy (TT)
Bacillary load	Multibacillary	Paucibacillary
Bacteriological index	4–6+	0–1+
Skin lesions	Many, symmetrical Margin is irregular Lesions appear as: ▪ Multiple nodules (lepromata) (Fig. 27.4A) ▪ Plaques and xanthoma-like papules Leonine facies and eyebrow alopecia is seen	One or few, asymmetrical Margin is sharp Lesions appear as: Hypopigmented, annular macules with elevated borders (Fig. 27.4B) Tendency towards central clearing
Nerve lesion	Nerve lesions appear late Hypoesthesia is a late sign	Early anesthetic skin lesion, Enlarged thickened nerves, Nerve abscess seen (common in BT)
Cell-mediated immunity (CMI)	CMI low	CMI normal
Lepromin test	Negative	Positive
Lymphocyte transformation test	Negative	Positive
CD4/CD8 T-cell ratio	1:2	2:1 (normal)
Humoral immunity	Exaggerated	Normal
Autoantibodies	Elevated	Not seen
VDRL test	Biological false positive	VDRL test negative
Antibodies to phenolic glycolipid-1(PGL-1)	Elevated in 95% of cases	Elevated in 60% of cases
Macrophages	Foamy type (lipid-laden)	Epithelioid type
Langhans giant cells	Not seen	Found

Abbreviations: VDRL, venereal disease research laboratory; BT, borderline tuberculoid leprosy



Figs 27.4A and B: A. Nodular lesions of lepromatous leporsy; **B.** Hypopigmented skin lesions of tuberculoid leprosy (arrows showing)

Source: Public Health Image Library, A. ID# 15508/ Dr. Andre J. Lebrun, B. ID# 15503/ Arthur E. Kaye, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Skin lesions** are few, asymmetric and sharply demarcated, consisting of macular anesthetic patches.
  - Nerve involvement occurs early. Nerves are often enlarged and thickened. Nerve abscess may be seen (common in TT and BT). Pronounced nerve damage may lead to deformities, particularly in the hands and feet.
  - Most common nerves involved are **ulnar** nerve followed by post auricular nerve.
  - Medial popliteal nerve is never involved.
- **Host immunity:**
  - CMI is adequate and the lepromin test is positive.
  - Humoral immune response is also normal.
  - Least infectious: TT patients are least infectious among all types.
  - Prognosis: TT patients have a good prognosis among all the types.

Other Categories of Leprosy

- **Borderline type:** It is seen in patients possessing characteristics in between tuberculoid and lepromatous types. They may shift to either TT or LL type, depending on chemotherapy or alterations in the host resistance.
- **Indeterminate type:** This denotes those early unstable cases with one or two hypopigmented macules and definite sensory impairment. Lesions are bacteriologically negative.
- **Pure neuritic type:** These patients develop neural involvement without any skin lesion. Cases are bacteriologically negative.

Immunune Response to M. Leprae

Immune respone to the lepra bacilli is the most important factor that determines the outcome of the infection.

- **Innate immunity**: People show a high degree of innate immunity to lepra bacilli so that only a minority of those infected develop clinical disease.
- **Humoral antibodies** are produced against various lepra antigens. However *M. leprae* being intracellular, antibodies have a minor role in disease control.
- **CMI:** It plays a vital role in the control of the disease. The category of leprosy develops, is determined by the CMI status of the individual (see the box below).
- **Genetic predisposition:** Association has been found between HLA DQ1, HLA MTI with LL type and HLA DR2 with TT type of leprosy.

Role of CMI in the Control of Leprosy

People with low CMI usually develop LL type of lesions:

- **Delayed hypersensitivity (DTH)** to the lepra antigens (which is usually positive in sensitized individual) is absent. Hence, the lepromin test is negative in these patients.
- **Virchow's Lepra cells:** The macrophages are able to phagocytose the lepra bacilli but instead of being killed, the bacilli proliferate inside the cells. Macrophages are often lipid laden called **Virchow's lepra cells**.
- **The deficiency in CMI appears to be antigen specific as**:
  - LL patients are not unusually susceptible to any other opportunistic infections, cancer, or AIDS or any conditions where CMI is important.
  - Delayed hypersensitivity against antigens of other organism is not suppressed. In sensitized individual, tuberculin reactivity remains positive.
- **CD4 : CD8 ratio:** It is reversed (1:2) in LL patients. CD8 T-cells predominate in the circulation, as well as in skin granulomas.
- **Predominant T_H2 response**: In LL patients, there occurs release of T_H2 specific cytokines such as IL4, IL5, IL6, IL10—which leads to an exaggerated antibody response.
- **Humoral immune response** is exaggerated in LL patients. There occurs polyclonal B-cell activation producing high titre of antibodies—both specific against lepra antigens as well as against several other antigens.
  - Autoantibodies are common.
  - Patients often show biological false positive reaction to VDRL test.
  - The albumin: globulin ratio is reversed.

People with intact CMI usually develop TT type lesions:

- **DTH response:** TT patients exhibit a delayed hypersensitivity response to lepra antigen (lepromin test is positive).
- **CMI is intact and there is predominant T_H1 response:**
  - In TT patients, there occurs release of T_H1 specific cytokines such as IL2, interferon γ which in turn activate the macrophages.
  - Activated macrophages phagocytose and kill the bacilli.
- **CD4: CD8 ratio** is normal (2:1). CD4 T-cells predominate in the circulation, as well as in skin granulomas.
- **TT patients show a normal humoral response**

Complications

Complication in leprosy patients may be of two types—deformities and allergic response (called **lepra reactions**).

Figs 27.5A to C: Deformities seen in untreated lepromatous leprosy: **A.** Saddle nose deformity; **B.** Bony deformity; **C.** Corneal opacity

Source: Public Health Image Library, ID#, A. 15456, B. 15459, C. 15494/ Dr. Andre J. Lebrun, Centers for Disease Control and Prevention (CDC), Atlanta *(with permission)*

Deformities

About 25% of untreated cases develop deformities in due course of time which may arise due to—(1) nerve injury leading to muscle weakness or paralysis, or (2) disease process (facial deformities or loss of eyebrow), or (3) infection or injury (ulcers).

Common deformities include (Fig. 27.5):

- **Face:** Leonine facies, sagging face, loss of eyebrow/eye lashes, saddle nose and corneal ulcers.
- **Hands:** Claw hand and wrist drop
- **Feet:** Foot drop, clawing of toes, inversion of foot, and plantar ulcers.

Lepra Reactions

Though leprosy runs as a chronic disease, several allergic type of acute exacerbations occur throughout its course, called lepra reactions which are of two types (Table 27.12).

Lepra Reaction Type-1

It occurs mostly in patients with borderline leprosy.

- **Manifestations include:** (1) acute inflammation of the existing lesions (skin lesions suddenly become reddish, swollen, warm and painful with characteristic edema), (2) appearance of new skin lesions, (3) neuritis (most common-ulnar nerve).
- There is a predominant T_H1 response with increased levels of IFN-γ and IL-2. T-cells bearing γδ receptors are often increased.
- If type 1 lepra reactions occurs:
  - Before start of treatment: It progresses towards LL (termed as **downgrading reactions**).
  - After the initiation of therapy, the case becomes more tuberculoid (termed as **reversal reactions**).
- **Treatment:** Patients usually respond well to glucocorticoids.

TABLE 27.12: Lepra reactions

Characters	Lepra reaction type I	Lepra reaction type II
Hyper-sensitivity	Type IV (delayed hypersensitivity)	Type III (immune complex-mediated)
Seen with	Borderline leprosy	Lepromatous variety (BL, LL)
Manifests as	Inflammation of previous lesions, new skin lesions and neuritis	Crops of painful erythematous papules which become nodular
Progresses as	If occurs before treatment —progresses towards LL (**down grading reaction**) If occurs after treatment— progresses towards TT (**reversal reaction**)	It usually occurs following the start of chemotherapy
T-helper response	T_H1 predominates	T_H2 predominates
Other organs	Usually not affected	Eyes, testes and kidney are affected
Treatment	Glucocorticoid	Glucocorticoid, thalidomide, clofazimine and antipyretics

Lepra Reaction Type-2

It develops mostly in lepromatous patients (LL or BL), following the institution of chemotherapy.

- Antibiotics kill the bacilli releasing the antigens which combine with circulating antibodies and the immune complexes formed are deposited in skin and various parts of the body.
- The most common feature is crops of painful erythematous papules, which become nodular termed as **erythema nodosum leprosum (ENL)**.
- Relapse is common and recurrent cases are more severe.
- There is a predominant T_H2 response with increased levels of IL-6 and IL-8.
- Tumor necrosis factor-α (TNF-α) plays a central role in the immunology of ENL.
- Treatment is started with glucocorticoids. Thalidomide or clofazimine should be initiated for nonresponsive or recurrent cases.

Lucio Phenomenon

It is an unusual reaction, seen in some cases of Mexico and the Caribbean; who have diffuse dermal infiltration without visible skin lesions (termed ***diffuse lepromatosis***).

Epidemiology

- **Source of infection:** Multibacillary (LL and BL) cases are the most important sources of infection. Asymptomatic cases can also have a role in transmission. Tuberculoid leprosy cases do not transmit infection efficiently.
- **Mode of transmission:** *M. leprae* has multiple routes of transmission. Portal of entry is either nose or skin.
  - Nasal droplet infection (aerosols containing *M. leprae*) is the most common mode. A sneeze from an untreated LL patient may contain >10^{10} lepra bacilli.
  - Contact transmission (skin):
    - Direct contact from person to person
    - Indirect contact with infected soil, fomites such as clothes and linens.
  - Direct dermal inoculation during tattooing.
- **Communicability:** Leprosy is not highly communicable. Intimate and prolonged contact is necessary for transmission. Only about 5% of spouses living with leprosy patients develop disease. The disease occurs more likely if contact occurs during childhood.
- **Environmental factors** that promote infection include people of rural areas, moist soil, humidity and overcrowding. Males are affected twice common than females.

Geographical Distribution

Once leprosy was worldwide in distribution, but now it is almost exclusively confined to the developing nations of Asia, Africa, Latin America, and Pacific.

- **SEAR** (South-East Asian Region) accounts for the highest disease burden globally: 53% of global prevalence, with 73% of all new cases detected in 2012.
- **Situation in India:** India accounts for maximum number of leprosy cases. Leprosy is widely prevalent in India, although the distribution is uneven.
  - However, with the help of National Leprosy Eradication Programme, the disease burden is declining in India.
  - The prevalence rate in India is about 0.68 cases per 10,000 population in 2012.
  - About 32 states/Union Territories (UTs) have already achieved the level of leprosy elimination i.e. prevalence rate of less than 1 case per 10,000 population.
  - Chhattisgarh, Dadra and Nagar Haveli are the only state/UT in which the prevalence rate remains above the level of leprosy elimination. Bihar lies at the borderline.

Laboratory Diagnosis

1. Smear Microscopy

Smear microscopy is done to demonstrate the acid fast bacilli in the lesions.

Specimen Collection

Total six samples are collected; four from skin (forehead, cheek, chin and buttock), one from ear lobe and nasal mucosa by nasal blow/scraping.

- **Slit skin smear** is the technique followed to collect the skin and ear lobe specimens.
  - The **edge of the lesion** is the preferred site. Lesion is cleaned with spirit, then is pinched up tight to minimise bleeding.
  - A 5 mm long incision is made with a scalpel, deep enough to get into the infiltrated layers.
  - After wiping off blood or lymph that may have exuded, the scalpel blade is rotated transversely to scrape the sides and base of the incision so as to obtain a tissue pulp from below the epidermis which is smeared uniformly over an area of 8 mm diameter on a slide.
- **Nasal specimens:** (1) **Nasal blow:** Early morning mucus material is collected by blowing the patient's nose on a clean cellophane sheet; or (2) **Nasal scraping:** By using a mucosal scraper to scrape the nasal septum sufficiently so as to remove a piece of mucous membrane, which is transferred onto a slide and teased out into a uniform smear. Nasal scrapings are not recommended as routine.
- **Biopsy** from the thickened nerves and nodular lesions may be necessary in some cases.

Appearance

The smears are stained by Ziehl–Neelsen technique by using 5% sulfuric acid for decolorization. Under oil immersion objective, red acid fast bacilli are seen, arranged singly or in groups (cigar like bundles), bound together by lipid-like substance, the glia to form **globi**. The globi are present inside the foamy macrophages called **Virchow's lepra cells or foamy cells** (Fig. 27.6).

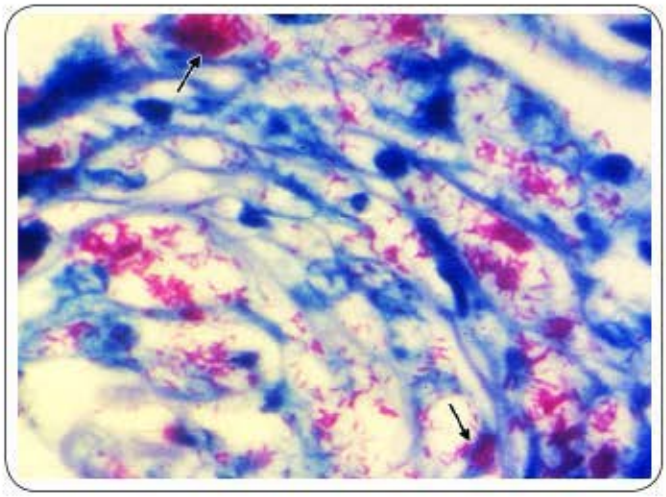


Fig. 27.6: Acid-fast staining showing numerous *Mycobacterium leprae* singly or in globi (arrows showing)

Source: Public Health Image Library, ID#, 15452/ Arthur E. Kaye, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Live bacilli** will be uniformly stained with parallel sides and round ends and length is five times the width.
- **Dead bacilli** are less uniformly stained and have fragmented and granular appearance.

Grading of the Smear

The smears are graded, based on the number of bacilli per oil immersion field (OIF) as follows:
1–10 bacilli in 100 OIF =1+
1–10 bacilli in 10 OIF = 2+
1–10 bacilli per OIF = 3+
10–100 bacilli per OIF = 4+
100–1000 bacilli per OIF = 5+
>1000 bacilli or bacilli in clumps and globi in each OIF = 6+
Bacteriological index (BI): It is based on the total number of bacilli (live and dead) seen per oil immersion field. The bacteriological index (BI) is calculated by totalling the number of pluses scored in all the smears and divided by the number of smears examined.
Morphological index (MI): It is expressed as the percentage of uniformly stained bacilli out of the total number of bacilli counted. MI is a better marker to monitor the treatment response. Following clinical improvement by treatment, the MI should fall down where as the BI may remain the same.
SFG percentage (solid, fragmented granular rod percentage): Since the percentage of solid, fragmented granular rods are recorded separately, this method gives better picture of bacterial morphology and is a more sensitive indicator of monitoring the treatment response than MI.

2. Mouse Foot Pad Cultivation

M. leprae is not cultivable either in artificial culture media or in tissue culture. The only certain way to cultivate *M. leprae* is by inoculating the specimens into foot pad of mice and keeping at 20°C for 6–9 months. Other animals such as nine banded armadillo can also be used.

- **Advantages:** (1) it is 10 times more sensitive than microscopy, (2) useful in detecting drug resistance, (3) evaluating the potency of drugs, (4) detects viability of the bacilli.
- **Disadvantages:** (1) time-consuming (6–9 months), and (2) ethical issues regarding use of animals.

3. Antibody Detection

- **FLA-ABS** (Fluorescent leprosy antibody absorption test): It is widely used to identify subclinical cases. It detects *M. leprae* specific antibodies irrespective of duration and stage of the disease. It claims to be 92% sensitive and 100% specific.
- **ELISA** detecting IgM antibodies to PGL-1 (phenolic glycolipid-1) antigen of *M. leprae* are found in 95% of patients with untreated LL patients and the titre decreases with effective therapy. However its sensitivity is low (60%) in TT patients.

4. Test for Detecting CMI (Lepromin test)

Lepromin test is discovered by Mitsuda (1919). It demonstrates the delayed hypersensitivity reaction and an intact CMI against the lepra antigen.

- **Procedure:** Standard lepromin antigens prepared from armadillo-derived lepra bacilli (lepromin -A), are increasingly used, replacing the earlier crude antigens. 0.1mL of lepromin antigen is injected intradermally to inner forearm and reading is taken at two occasions; at 48 hours and 21 days.
- **Early reading or Fernandez reaction:** Induration surrounded by erythema (red area) is produced at the site of inoculation within 24–48 hours.
  - Early reaction corresponds to that of tuberculin test and indicates a delayed hypersensitivity reaction to soluble constituents of lepra antigen.
  - Red area of >10 mm diameter is considered as positive, which indicates past exposure to lepra bacilli. However, it does not indicate active infection.
- **Late reading** or **Mitsuda reaction:** Reading is taken after 21days.
  - Positive test is indicated by a nodule formation of >5 mm size at the site of inoculation which ulcerates later on.
  - Late reaction is produced against the bacillary component of the lepra antigen and indicates that the patient's CMI is intact.
- **Uses of Lepromin test:** The late reaction is a useful tool to measure the immune status (CMI) of the individual. Lepromin test is said to be positive only when the CMI is intact. Thus, it can be used for:
  - **Classifying lesions of leprosy:** In TT patients with intact CMI, the test is strongly positive. Gradually the positivity becomes weaker as the patient progresses towards lepromatous end. In LL patients; the test is negative indicating a low CMI.
  - **Assessing prognosis:** Intact CMI (as in TT patients) indicates good prognosis.
  - **Assessing resistance to leprosy in individuals:** Lepromin negative persons are at higher risk of developing multibacillay leprosy than lepromin positive persons.

TREATMENT Leprosy

Because of risk of development of drug resistance to single drug, WHO recommends multidrug therapy (MDT) for treatment of leprosy (Table 27.13).
- Recommended drugs: Dapsone, rifampicin and clofazimine.
- Alternate drugs: Ethionamide, quinolones (ofloxacin), minocycline and clarithromycin.

WHO recommended treatment regimens are administered based on the clinical type of leprosy (Table 27.13).

TABLE 27.13: Clinical classification of leprosy and WHO treatment regimens

Criteria	Paucibacillary	Multibacillary
Skin lesions	1–5	6 or more
Nerve involvement	1	2 or more
Microscopy	Smear negative	Smear positive
Leprosy type	TT, BT and Intermediate	BB, BL, LL
Treatment regimen	▪ Dapsone (100 mg) given daily, self administered ▪ Rifampicin (600 mg) given once a month under supervision	▪ Dapsone (100 mg) given daily ▪ Rifampicin (600 mg) given once a month ▪ Clofazimine–300 mg once a moth under supervision, followed by 50 mg daily, self administered
Duration of treatment	Up to 6 months	Up to 1 year or till smear negative
Follow up	Annually till 2 years	Annually till 5 years

Prevention of Leprosy

Active case finding and effective treatment of cases is the most important measure to control leprosy.

- **BCG vaccine:** There is no effective vaccine available so far. Trials were done using BCG vaccine alone or in combination with killed lepra bacilli, ICRC bacillus.
- **Chemoprophylaxis:** Dapsone can be given to high risk household contacts of lepromatous patients.
- Hospitalized patients need not be isolated as transmission requires prolonged contact.

Leprosy Elimination

In 1992, the WHO launched a campaign to eliminate leprosy as a public health problem by year 2000. The goal was kept as <1 case per 10,000 population. India has achieved the status by December 2005. However, many other SEAR countries are yet to achieve this level. Though achieved the elimination level, still India accounts for the highest number of leprosy cases worldwide. Hence, the long term aim is to eradicate leprosy. The national leprosy eradication programme in India has been in operation since 1983.

However eradication of leprosy is difficult because of:

- Long and variable Incubation period
- Disputed mode(s) of transmission
- More subclinical cases
- Low immunity in patients with LL
- Absence of effective vaccine
- Bacterial resistance
- Complicated spectrum of disease
- Poor patient compliance because of longer duration of treatment
- Social issues

The national institutes for leprosy are:

- **National JALMA** Institute of Leprosy and other Mycobacterial Diseases, Agra.
- **CLTRI** (Central Leprosy Training and Research Institute), Chengalpattu, Tamil Nadu.

EXPECTED QUESTIONS

I. Essay:

1. Rajesh, a 28-years-old male, was admitted to the hospital with complaints of low grade fever, loss of weight and appetite and chronic cough with expectoration for past 6 months. Sputum examination revealed long, slender and beaded acid fast bacilli.
   a. What is your provisional diagnosis?
   b. Describe the pathogenesis of this condition?
   c. Mention the laboratory diagnosis in detail?
   d. Mention briefly about drug resistance that can occur in this etiological agent?

II. Write short notes on:

1. BCG vaccine
2. Tuberculin test
3. Laboratory diagnosis of leprosy
4. MDR-TB
5. Nontuberculous mycobacteria

III. Multiple Choice Questions (MCQs):

1. Humans become infected by *M. tuberculosis* commonly by:
a. Ingestion b. Contact
c. Inhalation d. Inoculation

2. Which of the following mycobacteria are micro-aerophilic?
a. *M. tuberculosis* b. *M. bovis*
c. *M. leprae* d. None of the above

3. A positive tuberculin test is indicated by an area of induration of:
a. <5 mm in diameter b. 6–9 mm in diameter
c. ≥ 10 mm in diameter d. No induration

4. Which of the following mycobacteria produces Buruli ulcer?
a. *M. kansasii* b. *M. tuberculosis*
c. *M. ulcerans* d. *M. marinum*

5. Fish tank granuloma is caused by:
a. *M. kansasii* b. *M. fortuitum*
c. *M. marinum* d. *M. ulcerans*

6. The generation time of lepra bacilli is:
a. 20 minutes b. 2 hours
c. 20 hours d. 12–13 days

Answers

1. c **2.** b **3.** c **4.** c **5.** c **6.** d

CHAPTER 28

Miscellaneous Gram-positive Bacilli

Chapter Preview

- Actinomycetes
  - Actinomyces species
  - Nocardia species
  - Actinomadura species
- Listeria species
- Erysipelothrix species
- Tropheryma whipplei

ACTINOMYCETES

Actinomycetes are diverse group of gram-positive, non-motile, non-sporing, non-capsulated bacilli arranged in chains or branching filaments. Though they are true bacteria, but similar to fungi, they form a mycelial network of branching filaments. They are related to mycobacteria and corynebacteria. Most of them are soil saprophytes or normal human commensals. Important genera include:

- *Actinomyces:* They are anaerobe and non-acid fast; produce a clinical condition called actinomycosis.
- *Nocardia*: They are aerobe and acid fast; cause actinomycetoma and pulmonary infection.
- *Actinomadura:* They are aerobe and non-acid fast; cause actinomycetoma.
- *Streptomyces:* They are aerobe and non-acid fast; rarely cause actinomycetoma in man. They also remain as an important source of antibiotics such as streptomycin.
- Thermophilic actinomycetes such as *Micropolyspora* and *Thermoactinomyces* can cause hypersensitivity pneumonitis (farmer's lung and bagassosis).

Actinomyces

Actinomyces are soil saprophytes and commensals of oral cavity. In humans they cause actinomycosis. *A. israelii* is the most common species infecting man. Others such as *A. naeslundii* and *A. odontolyticus* are rare pathogens.

Pathogenesis

Actinomycosis is a chronic suppurative and granulomatous infection characterized by multiple abscesses with formation of sinuses, discharge containing granules and on later stage; fibrosis and tissue destruction.

- The name refers to ray-like appearance of the organism in the granules (*Actinomyces*, meaning ray fungus).
- **Mode of infection:** As *Actinomyces* are commensals of oral cavity, the infection is mostly **endogenous** and may result from trauma, e.g. dental extraction.
- The bacteria bridge the mucosal or epithelial surface of the mouth, grow in an anaerobic niche, induce a mixed inflammatory response, and form painless indurated swelling with sinuses which may drain pus containing granules to the skin surface.
- The infection may spread to the neighbouring organs including the bones and induce tissue destruction.
- Often, the hard indurated swellings are mistaken as malignant tumors.

Clinical Manifestations

Cervicofacial actinomycosis: This is the most common form, usually presents as a painless, slow-growing, hard mass with cutaneous fistulas, a condition commonly known as **lumpy jaw** (Fig. 28.1A).

Other forms are rare such as:

- **Abdominal form:** It occurs due to spillage of intestinal flora secondary to bowel surgery or other conditions of bowel such as appendicitis.
- **Pelvic form:** It occurs following intrauterine contraceptive devices (IUCDs) insertion.
- Brain abscesses
- Bone destruction and soft tissue infections
- **Disseminated form:** It may occur due to hematogenous spread. Lungs and liver are the common sites; where multiple nodules are formed.
- Dental caries and periodontal diseases: Mainly caused by *A. naeslundii* and *A. odontolyticus*.

Laboratory Diagnosis

Specimen

Based on the affected site, the specimens collected include discharge from the sinuses or fistula, rarely bronchoalveolar lavage, sputum or tissue sections.

Direct Microscopy

Pus discharge is thoroughly washed in saline in a test tube and the sediment is collected that contains gritty, white or yellowish **sulfur granules**, of < 5 mm in size. Granules are crushed between two slides and smears are made.

- **Gram-staining (Brown–Brenn modification):** It shows a central mass of gram-positive filamentous bacilli, radiating peripherally with hyaline, club-shaped ends. Clubs are composed of complexes formed due to interaction of bacteria derived polysaccharide and protein with host cell salts and polypeptides (Fig. 28.1B).
- Granules of actinomycosis are hard and not emulsifiable which differentiates them from granules produced in other conditions.
- *Actinomyces* species can also be detected directly from the sample by methods such as:
  - Fluorescent antibody techniques using fluorescent tagged species specific monoclonal antibodies.
  - Fluorescent in situ hybridization (FISH) using species specific probes.
- **Histopathological staining** such as hematoxylin-eosin and Gomori's stained tissue sections may reveal granules composed of eosinophilic clubs surrounding basophilic filaments and inflammatory cells such as neutrophils and foamy macrophages (sun-rays appearance) (Fig. 28.1C).

Culture

Pus containing sulfur granules are washed and cultured anaerobically at 37°C on media such as:

- Thioglycollate broth: Growth of *A. israelii* resembles **fluffy balls** at the bottom of the tube, this can be differentiated from other species (*A. bovis* produces uniform turbidity).
- Brain heart infusion (BHI) agar: It forms small **spidery colonies** at 48 hours which become enlarged and heaped up in 10 days.

Species Identification

It is done when the culture isolate is subjected to:

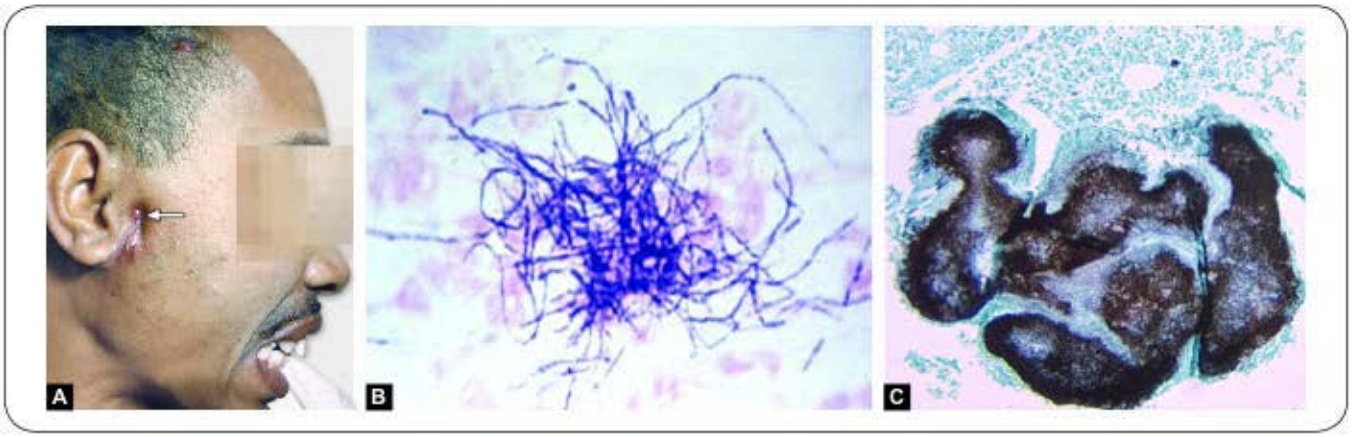
- Biochemical reactions
- Gas-liquid chromatography (GLC) for detection of the products of glucose metabolism.
- Molecular methods, such as PCR-RFLP are also available for speciation.

TREATMENT — ***Actinomycetes***

- Penicillin is the drug of choice, given for 6–12 months duration to prevent relapse. Erythromycin or tetracycline can be given to people with penicillin allergy.
- Surgical removal of the affected tissues may be required for extensive lesions.

Nocardia

Nocardia species (named after Edmond Nocard, 1898) are gram-positive branching filamentous bacilli similar to *Actinomyces*; however, they differ from the later by being aerobic and acid-fast (Table 28.1). They are environmental saprophytes found in soil and vegetations. Though more than 50 species have been identified, only few (nine)



Figs 28.1A to C: A. Actinomycosis (painless, slow-growing, hard mass with cutaneous fistula) (arrow showing); *Actinomyces israelii;* **B.** Gram-positive filamentous bacilli; **C.** Gomori's stained smear showing sun-ray appearance

Source: A. Public Health Image Library, ID# 2856, C. ID# 10601/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TABLE 28.1: Differences between *Actinomyces* and *Nocardia*

Features	*Actinomyces*	*Nocardia*
Acid-fastness	Nonacid-fast	Partially acid-fast
Oxygen requirement	Anaerobe	Obligate aerobe
Sugar	Fermenter	Utilizes sugar oxidatively
Habitat	▪ Found as oral flora ▪ Infections occur endogenously	▪ Usual habitat is soil ▪ Infections occur exogenously
Risk factors	Disease occurs in immunocompetent host also	Usually affects people with low immunity
Clinical forms	Cervicofacial, abdominal and others	Pulmonary, CNS forms, Actinomycetoma
Granules	**Sulfur granules** are hard and not emulsifiable, consist of branching filamentous bacilli and surrounded by clubs **(sun-ray appearance)**	▪ Granules are soft and lobulated and also show sun-ray appearance. ▪ Commonly found in mycetoma, rare in other conditions
Culture	▪ **Spidery molar** teeth colony in solid media ▪ **Fluffy ball** at bottom of the liquid medium	Colonies are creamy, wrinkled and pink. Isolation is done in: ▪ Selective media ▪ Paraffin bait technique ▪ LJ medium
Drug of choice	Penicillin	Sulfonamide or cotrimoxazole

species are associated with human disease. *N. asteroides* (so named due to its star-shaped colonies) and *N. brasiliensis* are the most common pathogens.

Pathology and Pathogenesis

Nocardiosis occurs worldwide, more common among adult males. Soil is the natural habitat of *Nocardia*. Infection is acquired from soil either by:

- **Inhalation of fragmented bacterial mycelia:** Leads to development of pulmonary nocardiosis that may disseminate later. It is often associated with various species such as *N. asteroides, N. cyriacigeorgica, N. farcinica* and *N. pseudobrasiliensis.*
- **Transcutaneous inoculation of the bacteria:** Leads to various cutaneous and sub cutaneous manifestations (e.g. mycetoma). This is often associated with various species such as *N. brasiliensis, N. asteroides* and rarely by *N. otitidiscaviarum* and *N. transvalensis.*
- Person-to-person spread is not known.

The characteristic histologic feature seen in nocardiosis is an abscess with extensive neutrophil infiltration and prominent necrosis, surrounded by granulation tissue. Nocardiae survive within the neutrophils by:

- Neutralization of oxidants
- Prevention of phagosome-lysosome fusion
- Prevention of phagosome acidification

Risk Factors

Cell-mediated immunity plays an important role in controlling the disease. Hence nocardiae act as opportunistic pathogen, tend to occur frequently in immunocompromised conditions including AIDS, corticosteroid treatment, organ transplantation and tuberculosis.

Clinical Manifestations

Pulmonary Nocardiosis

Lobar pneumonia is the most common form, characterized by subacute onset of cough with thick, purulent sputum. It may rarely spread directly to adjacent tissues, leading to pericarditis, mediastinitis, laryngitis, tracheitis and bronchitis.

Extrapulmonary (Disseminated) Nocardiosis

In half of the pulmonary nocardiosis cases, dissemination occurs via blood. It typically presents as subacute abscess. Brain is the most common site followed by skin, kidneys, bone and muscle. Brain abscesses are usually supratentorial, often multiloculated, and may be single or multiple. Meningitis is uncommon.

Actinomycetoma

Mycetoma is a chronic granulomatous condition affecting subcutaneous tissues of the feet and hands, characterized by:

- Subcutaneous nodular swelling
- Multiple sinuses
- Discharge containing granules
- Tendency of spreading to adjacent bones (bony deformities).

Mycetoma usually affects people residing in tropical countries. The organism enters through skin on exposure to contaminated soil. Broadly, mycetoma is classified into two types:

1. **Eumycetoma:** It is caused by fungi such as *Madurella* (Chapter 52 for detail).
2. **Actinomycetoma:** It is caused by filamentous bacteria such as *Nocardia, Actinomadura* and *Streptomyces somaliensis.*

Laboratory Diagnosis

Specimen

Depending on the site affected, various specimens collected such as sputum, pus from abscess and granules.

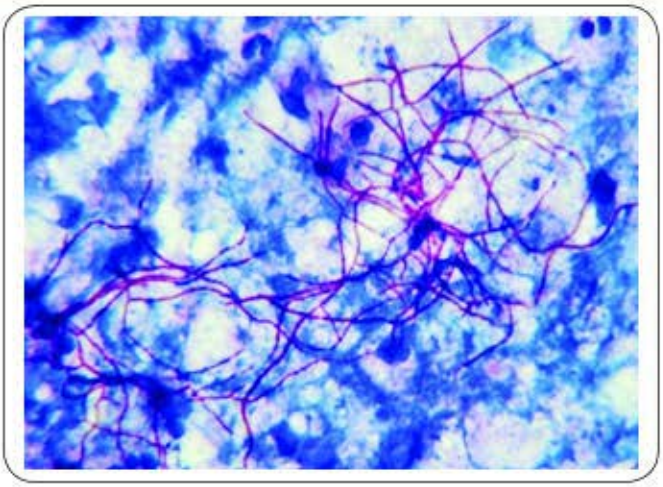


Fig. 28.2: Acid-fast filamentous branching bacilli of *Nocardia* (modified acid-fast stain)

Granules present in discharge are collected in sterile gauze or loop by pressing the sinuses from the periphery to express them out (as in case of actinomycetoma).

Direct Microscopy

- **Gram-staining (Brown-Brenn modification):** Reveals gram-positive branching and filamentous bacilli of width 0.5–1 µm. They stain irregularly as their filaments are beaded. Sputum examination may show numerous lymphocytes and macrophages, some of which contain branching bacilli.
- **Modified acid-fast staining** using 1% sulfuric acid as decolorizer (Kinyoun method): Nocardiae are partially acid fast and appear as branching and filamentous red colored acid-fast bacilli (Fig. 28.2).
- Granules are washed several times in saline, crushed between two slides and observed under microscope. Granules are 0.5–2 mm sized microcolonies composed of branching filamentous bacilli.
- **Histopathology (H and E stain) of the granules:** Shows multilobulated with sun ray appearance.

Culture

Nocardiae are obligate aerobes that grow on various media such as brain heart infusion agar and Sabouraud dextrose agar (SDA) when incubated at 37°C for 2 days to 2 weeks. Colonies are creamy, wrinkled, pigmented (orange or pink colored due to carotenoid-like pigments) and adhere firmly to the medium. Some colonies possess abundant aerial growth and have a cotton wool ball appearance.

Recovery of *Nocardia* from the samples containing *Actinomadura* and *Streptomyces* can be done by:

- **Using selective media:**
  - Buffered yeast extract containing polymyxin and vancomycin
  - Sabouraud dextrose agar with chloramphenicol
- **Paraffin bait technique:** Media using paraffin as the sole carbon source have been shown to be effective for isolation of nocardiae from soil and clinical samples.
- **Lowenstein-Jensen medium:** Produces moist glabrous colonies (differentiates from mycobacteria).

Biochemical Identification

Nocardia species are non-motile, catalase positive and utilize a number of sugars oxidatively. Various biochemical tests are done for species identification such as:

- Decomposition of casein, hypoxanthine, tyrosine
- Growth in lysozyme
- Acetamide utilization
- Growth at 45°C for 3 days
- Acid from rhamnose

TREATMENT ***Nocardia***

- Sulfonamides are the drug of choice.
- Cotrimoxazole (sulfamethoxazole and trimethoprim) can be used as alternative.
- Duration of treatment is about:
  - 6–12 months for pulmonary, extrapulmonary forms and for actinomycetoma
  - 2 months for cellulitis and lymphocutaneous syndrome
- Aspiration or drainage of the abscesses should be carried out to limit the spread of infection.

Actinomadura

Actinomadura is the most frequent cause of actinomycetoma, significantly out numbering the cases caused by *Nocardia*.

- *Actinomadura madurae* and *A. pellettieri* are important species.
- Granules are usually white to yellow except in case of *A. pellettieri* that produces red colored granules.
- Microscopy of the specimens containing granules reveals branching filamentous bacilli.
- Colonies have a **molar tooth** appearance after 48 hours in culture with sparse aerial growth.
- Speciation is on the basis of biochemical tests.
- Most isolates are susceptible to amikacin and imipenem.

LISTERIA MONOCYTOGENES

Listeria monocytogenes is a food-borne pathogen that can cause serious infections, particularly in neonates, pregnant women and elderly people.

Epidemiology

L. monocytogenes is a ubiquitous saprophyte. It has been isolated from birds causing epizootic disease and also found as asymptomatic carriage. It causes abortion and circling disease, a form of basilar meningitis in sheep and cattle.

Human Infection

- **Mode of transmission:** It is transmitted most commonly through contaminated food followed by vertical transmission (mother to fetus).
- **Age:** Listeriosis is common among extremes of age (neonate and old age).
- **Other risk factors:** Pregnant women and immunocompromised individuals are at higher risk.
- Due to its ability to survive refrigeration (4°C), it is **commonly found in stored foods** especially aged soft cheeses, packaged meats, milk and cold salads.
- Listeriosis is most often sporadic, although outbreaks do occur.

Pathogenesis

Important steps involved in pathogenesis are entry into cells, intracellular growth and cell-to-cell spread.

- **Entry:** Entry into intestinal epithelium is mediated by host surface protein **internalins**.
- **Intracellular survival:** It is a facultative intracellular organism. Survival inside the host cells is mainly due to inhibition and lysis of phagosome by forming pores (mediated by listeriolysin O).
- Surprisingly, it is observed that there is an inverse relationship between toxicity and virulence, i.e. more cytotoxic strains are less virulent. This is because, as an intracellular pathogen, *L. monocytogenes* benefits from leaving its host cell unharmed.
- **Direct cell-to-cell spread:** *Listeria* escapes into the host cytoplasm, expresses a surface protein, *Act A*, that mediates the nucleation of host actin filaments which in turn helps the bacterium to reach cell membrane and migrate to the adjacent epithelial cells/macrophages (mediated by listeriopods).

Clinical Manifestations

Clinical manifestation depends on the age of the patient and other risk factors, such as immunosuppression. Most of the human infections are caused due to serotypes 1/2a, 1/2b, and 4.

- **Neonatal listeriosis:** Two clinical presentations are recognized—early-onset and late-onset neonatal disease (Table 28.2)
- **In pregnant women:** It affects both mother and the fetus. (1) Fetal complications, such as abortion, preterm delivery lead to early onset disease; (2) Maternal complications, such as flu-like symptoms, bacteremia and rarely meningitis.
- **Adults:**
  - It produces manifestations such as bacteremia and meningitis.
  - Common risk factor is immunosuppression (steroid therapy, HIV, diabetes, malignancy).

TABLE 28.2: Differences between early and late onset neonatal listeriosis

Early onset neonatal disease	Late onset neonatal disease
Occurs <5 days of birth (Mean age 1.5 days)	Occurs >5 days of birth (Mean age 14.2 days)
Acquired from maternal genital flora	Acquired from environment
Associated with obstetrical complications like premature delivery and low birth weight	Not associated
Most common form is neonatal sepsis	Most common form is neonatal meningitis
Granulomatosis infantiseptica: Occurs rarely, characterized by miliary microabscesses and granulomas, mostly in skin, liver and spleen	Not seen
Mortality rate is >30%	Mortality rate is <10%
Does not cause nosocomial outbreaks	Nosocomial outbreaks are seen

  - *Listeria* can cause meningitis in kidney transplanted patients after 1 month.
  - It also causes gastroenteritis following consumption of contaminated milk, meat and salads.

Laboratory Diagnosis

- **Specimens** collected are CSF, blood and amniotic fluid.
- **Gram-stain:** Gram-positive short coccobacilli, often confused with diphtheroids.
- **Motility:** It shows **tumbling type of motility** at 25°C but non-motile at 37°C (called **differential motility,** which is due to temperature dependent flagella expression).
- **Culture:** It grows on blood agar (β hemolytic colonies), chocolate agar and selective media, such as **PALCAM agar** (polymyxin, acriflavine, lithium chloride, ceftazidime, aesculin and mannitol).
- Growth improves on refrigeration at 4°C (called **cold enrichment**) in trypticase soy broth followed by subculture on to plates and incubated at 37°C.
- **Biochemical reaction:** It is catalase positive, can grow in presence of 10% salt and low pH. *L. monocytogenes* is differentiated from other *Listeria* species by the following tests.
  - It shows a positive CAMP test when streaked at a right angle to *Staphylococcus aureus* (enhanced arrowhead hemolysis, Chapter 22).
  - It ferments glucose, maltose, L-rhamnose and alpha methyl D-mannoside, producing acid without gas.
- **CSF examination:** It shows elevated pressure, increased protein, and increased lymphocyte count.

TREATMENT — Listeriosis

- Ampicillin is the drug of choice, given for 2–3 weeks in combination with gentamicin for synergistic effect.
- Cotrimoxazole is given for patients with penicillin allergy.
- Cephalosporins are not effective.

Prevention

Food borne listeriosis can be prevented by thorough cooking of food, washing fresh vegetables, carefully cleaning utensils and avoiding consumption of unpasteurized dairy products.

ERYSIPELOTHRIX RHUSIOPATHIAE

Pathogenesis

Erysipelothrix rhusiopathiae (or *E. insidiosa*) is widely distributed in animals and fishes. It causes erysipelas especially in swine, turkeys, ducks and sheep.

- Human infection occurs by direct inoculation from animals or animal products.
- High risk groups are animal handlers (abattoir workers, butchers) and fishermen.
- **Erysipeloid:** This is the most common form of human infection by *Erysipelothrix*; characterized by violaceous swelling with severe pain, but no pus (differentiates it from staphylococcal and streptococcal erysipelas where pus is seen at the infection site). Most common site is fingers (called "**seal finger**" **and** "**whale finger**").
- Rare clinical forms are diffuse cutaneous form and bacteremia with endocarditis.

Laboratory Diagnosis

- **Gram-staining:** *E. rhusiopathiae* is a gram-positive bacillus that appears singly, in short chains or in long non-branching filaments.
- **Culture:** On blood agar, it produces small transparent glistening alpha-hemolytic colonies.
- The colony morphology and Gram-stain appearance vary depending upon the growth medium, incubation temperature and pH.
- **Biochemical reactions:** It is catalase negative, oxidase negative and indole-negative. The characteristic feature is it produces hydrogen sulfide on triple sugar iron agar, turning the color of the medium to black.

TREATMENT — Erysipeloid

Erysipelothrix is highly susceptible to penicillin G. It is the drug of choice for severe infections. The organism is intrinsically resistant to vancomycin.

TROPHERYMA WHIPPLEI

Tropheryma whipplei is a gram-positive actinomycetes, not closely related to any known genus. It is the agent of **Whipple's disease** affecting the small intestine.

- Whipple's disease is characterized by fever, abdominal pain, diarrhea, weight loss and migratory polyarthralgia. Mesenteric lymph nodes of the small intestine are primarily involved.
- **Laboratory diagnosis:**
  - Histopathological staining of intestinal biopsy shows prominent macrophage infiltration and fat deposition and characteristic pathognomonic vacuoles within the macrophage containing periodic acid-Schiff (PAS) stain positive bacilli.
  - Culture of *T. whipplei* has been unsuccessful.
  - Polymerase chain reaction (PCR) targeting 16S ribosomal RNA can be done to identify the bacilli.

TREATMENT — Whipple's disease

- Penicillin, ampicillin, tetracycline, or cotrimoxazole for 1–2 years.
- Hydroxychloroquine for 12–18 months.
- Relapse: Any treatment lasting for less than one year has an approximate relapse rate of 40%.

EXPECTED QUESTIONS

I. Write short notes on:

1. Pathogenesis of *Listeria monocytogenes*
2. Actinomycetoma

II. Multiple Choice Questions (MCQs):

1. Early onset neonatal disease caused by *Listeria-monocytogenes* is characterized by all except:
   a. Acquired from maternal genital flora
   b. Presents as neonatal sepsis
   c. Mortality rate is less than 10%
   d. Does not cause nosocomial outbreaks

2. In erysipeloid, the route of infection is:
   a. Direct inoculation
   b. Ingestion
   c. Inhalation
   d. None of the above

3. Which of the following actinomycete is acid fast?
   a. *Streptomyces*
   b. *Actinomadura*
   c. *Nocardia*
   d. *Actinomyces*

Answers

1. c **2.** a **3.** c

CHAPTER 29

Enterobacteriaceae-I

Chapter Preview

- General Properties
- Escherichieae
  - Escherichia
  - Shigella
- Edwardsielleae
  - Edwardsiella
- Citrobactereae
  - Citrobacter
- Klebsielleae
  - Klebsiella
  - Enterobacter
  - Hafnia
  - Serratia
  - Pantoea
- Proteeae
  - Proteus
  - Morganella
  - Providencia
- Yersinieae
  - Yersinia
- Erwinieae
  - Erwinia

FAMILY CHARACTERS (GENERAL PROPERTIES)

Members of the family Enterobacteriaceae should have the following properties:

- They are gram-negative bacilli
- Aerobes and facultative anaerobes
- Nonfastidious, can grow in ordinary media like nutrient agar.
- Ferment glucose to produce acid with or without gas.
- Reduce nitrate to nitrite.
- They produce catalase (except *Shigella dysenteriae* type-1).
- They do not produce oxidase.
- They are generally motile with peritrichous flagella, except some members which are nonmotile, such as *Shigella* and *Klebsiella*.
- Natural habitat: Most of them are commensals in human intestine, called **coliform bacilli**, e.g. *Escherichia, Klebsiella, Proteus, Morganella, Providencia* and *Citrobacter,* etc. The exceptions are *Shigella*, *Salmonella* which are enteric pathogens, not commensal.

Classification

- **The oldest method of classification** of family Enterobacteriaceae was based on fermentation of lactose on MacConkey agar (Table 29.1). It is still the most widely used classification, has a great practical application in laboratories to differentiate various members.
- **Newer methods of classification:** After the availability of molecular methods, the taxonomy is greatly changed. Currently, three classifications of Enterobacteriaceae are in use.
  1. Bergey's manual (1984)
  2. Edwards-Ewing classification (1986)
  3. Farmer and Kelley classification (1991)

All the three classifications are similar, though not totally identical and have certain differences. However the basic approach is same. The family is further classified into → tribe → genus → spevcies.

The tribe concept was proposed by Ewing. However other classifications directly classify family into genus and species. Use of tribe has a great impact in laboratory

TABLE 29.1: Classification of family Enterobacteriaceae based on lactose fermentation

Groups	Lactose fermentation	Colonies on MacConkey agar	Examples
Lactose fermenters (LF)—all are coliform bacilli	Ferment lactose-producing acid	Produce pink-colored colonies, (acid changes the color of neutral red indicator to pink)	*Escherichia* *Klebsiella*
Non lactose fermenters (NLF)	Do not ferment lactose	Produce pale or colorless colonies	*Salmonella, Shigella, Proteus, Morganella, Providencia* and *Yersinia*
Late lactose fermenters (LLF or previously called **paracolon bacilli**)	Ferment lactose after 2–8 days of incubation	At 24 hours of incubation—produce pale or colorless colonies After 2 days—produce pink color colonies	*Shigella sonnei*

TABLE 29.2: Ewing's classification of family Enterobacteriaceae

Tribe	Genus
Tribe I: Escherichieae	*Escherichia* *Shigella*
Tribe II: Edwardsielleae	*Edwardsiella*
Tribe III: Salmonelleae	*Salmonella*
Tribe IV: Citrobactereae	*Citrobacter*
Tribe V: Klebsielleae	*Klebsiella* *Enterobacter, Hafnia* *Serratia, Pantoea*
Tribe VI: Proteeae	*Proteus* *Morganella* *Providencia*
Tribe VII: Yersinieae	*Yersinia*
Tribe VIII: Erwinieae	*Erwinia*

for easy identification, as genera under each tribe share common properties. Hence, Ewing's classification is followed in this book (Table 29.2).

The biochemical reactions of various genera of the family Enterobacteriaceae are listed in Table 29.3.

TRIBE I: ESCHERICHIEAE

ESCHERICHIA COLI

It was described first by Escherich in 1885. *E. coli* is the most important species encountered as human pathogen.

- It is also the most common aerobe to be harbored in the gut of humans and animals.
- After excreted in feces, it remains viable only for some days in the environment.
- Hence, detection of *E. coli*, especially a variant called **thermotolerant *E. coli*** (survives at 44°C) is taken as an indicator of recent contamination of drinking water with human or animal feces.
- Other species are less important as human pathogens. These include *E. fergusonii, E. hermannii* and *E. vulneris* which are rarely isolated from clinical specimens.

Virulence factors of *E. coli*

Virulence factors of *E. coli* may be grouped into surface antigens and toxins.

Surface antigens

E. coli possesses four surface antigens—(1) somatic (O), (2) flagellar (H), (3) capsular antigens (K), and (4) fimbrial antigen.

- Serotyping of *E. coli* is based on agglutination with the specific antisera directed against each surface antigen.
- So far more than 170 O serotypes, 100 K serotypes and 75 H serotypes of *E. coli* have been recognized.
- The strain of *E. coli* is designated based on the serotype number of its antigens; for example, O121: K37: H8.

1. Somatic or O antigen:

- It is the lipopolysaccharide (LPS) antigen.

Contd...

Contd...

- It is heat-stable.
- Occasionally, it cross reacts with O antigens of other species.
- Early O serotypes are usually the commensals of intestine.
- Late O serotypes are the diarrhoea producing strains.
- Serotyping is done by slide agglutination with specific O antisera.
- O antigen is the most important virulence factor, responsible for endotoxic activity; it protects the bacteria from phagocytosis and bactericidal effect of complement.

2. Flagellar or H antigen (H from *Hauch*, meaning film of breath).

- It is heat labile
- Presence of H antigen (flagella) makes the bacteria motile, hence contributing to their virulence.

3. Capsular or K antigen (K for Kapsel, German for capsule)-

- It is the polysaccharide capsular antigen present on the envelope or microcapsule of a few strains of *E. coli*.
- When present, it encloses the O antigen and renders the strain inagglutinable by the O antiserum.
- It may also contribute to virulence by inhibiting phagocytosis.
- It is expressed by only few strains of *E. coli*; e.g. those causing neonatal meningitis, pyelonephritis and septicemia.

4. Fimbrial antigen (pilus) is the organ of adhesion, helps in attachment and colonization. It is expressed by a few strains of *E. coli*. Various fimbrial antigens are:

- **CFA** (colonization factor antigen): It is a type of fimbriae expressed by enterotoxigenic *E. coli*.
- **Mannose resistant fimbriae** (e.g. P, M, S, F1C and Dr fimbriae): They hemagglutinate with RBCs that is not inhibited by mannose. These are expressed by uropathogenic *E. coli* and help in colonization of these strains onto uroepithelial cells.
- **P fimbriae** bind specifically to the P blood group antigens present on human RBCs and uroepithelial cells.

Toxins

The exotoxins secreted by *E. coli* are of several types:

- **Enterotoxins:** They are produced by diarrheagenic strains of *E. coli*. They are of three types; heat labile toxin, heat stable toxin and verocytotoxin (all have been described in detail in Table 29.4).
- **Hemolysins:** They are produced more commonly by virulent strains of *E. coli* (especially pyelonephritis strains); however, their role in pathogenesis is unclear.
- **Cytotoxic necrotizing factor 1** (CNF1) and **secreted autotransporter toxin** (SAT): They are cytotoxic to bladder and kidney cells.
- **Siderophores** (i.e. aerobactin)—Helps in iron uptake.

Clinical Manifestations

E. coli is one of the most common pathogen encountered clinically and has been associated with various manifestations.

TABLE 29.4: Various properties of enterotoxins of *Escherichia coli*

LT (heat-labile toxin)	ST (heat-stable toxin)	Verocytotoxin or Shiga-like toxin
Produced by: Enterotoxigenic *E. coli*	**Produced by:** Enterotoxigenic *E. coli*	**Produced by:** Enterohemorrhagic *E. coli*
It resembles cholera toxin in its structure and function, but it is less potent than the latter. **Mechanism of action:** It has 2 peptide fragments: A and B ***Fragment B*:** It is the binding fragment, has five subunits. It binds to GM1 ganglioside receptors present on the intestinal epithelium following which A fragment is internalized and cleaved into A1 and A2 peptides. ***Fragment A*:** ▪ Fragment A2 helps in tethering A and B subunits together ▪ Fragment A1 is the active fragment (27 kDa), causes ADP ribosylation of G protein → upregulates the activity of adenylate cyclase → results in the intracellular accumulation of cyclic AMP (adenosine monophosphate) → leads to increased outflow of water and electrolytes into the gut lumen, with consequent diarrhea.	ST is of two types: ST-I and ST-II **Mechanism of action:** ***ST-I*:** Binds to the guanylate cyclase C → increased production of cyclic guanosine monophosphate (cGMP) → fluid accumulation in gut lumen → diarrhea ***ST-II*:** Though it causes fluid accumulation (in young piglets), the mechanism is not known yet, it is not through cAMP or cGMP mediated.	It is so named because it is cytotoxic to Vero cell lines. Also called **Shiga-like toxin** as it resembles Shiga toxin in its structure and function. **Mechanism of action:** It has two fragments: A and B ***Fragment B*** binds to a globotriosyl ceramide (Gb3) receptor on intestinal epithelium ***Fragment A*** is the active fragment. It inhibits protein synthesis by inhibiting 28S subunit of 60S subunit ribosome. **Two types** of Shiga-like toxin are known to exist: Stx1 and Stx2
Plasmid-coded	Plasmid-coded	Bacteriophage-coded
Detection of LT: **In *vivo tests*:** Ligated **rabbit ileal loop** test is positive (fluid accumulation in the loop) only after 18 hours Adult rabbit skin test is positive **In *vitro tests*:** Tissue culture tests: ▪ Steroid production in Y1 mouse adrenal cell culture ▪ Elongation in Chinese hamster ovary cells Precipitin test (Eiken's test) positive	**Detection of ST:** **In *vivo tests*:** Ligated rabbit ileal loop test – positive (fluid accumulation) at 6 hours Infant mouse intra gastric test is positive at 4 hours **In *vitro tests*:** Tissue culture tests are negative. Eiken's test is negative	**Detection of VT:** Serologically—Latex agglutination, ELISA Molecular methods—using specific DNA probe Cytotoxicity on Vero and HeLa cell lines
ST and LT can also be detected and differentiated from each other by: Serological tests, such as latex agglutination and ELISA Molecular methods- using LT and ST specific DNA probe		

- **Urinary tract infection** (UTI): It is caused by uropathogenic *E. coli* (UPEC) (described later)
- **Diarrhea**: It is caused by six types of diarrheagenic *E. coli* (described later)
  1. Enteropathogenic *E. coli* (EPEC)
  2. Enterotoxigenic *E. coli* (ETEC)
  3. Enteroinvasive *E. coli* (EIEC)
  4. Enterohemorrhagic *E. coli* (EHEC)
  5. Enteroaggregative *E. coli* (EAEC)
  6. Diffusely adherent *E. coli* (DAEC)
- **Other infections:**
  - Abdominal infections: *E. coli* is the most common cause of both primary bacterial peritonitis (occurs spontaneously) and secondary bacterial peritonitis (occurs secondary to intestinal perforation leading to spillage of commensal *E. coli* from intestine). It also causes visceral abscesses, such as hepatic abscess.
  - Pneumonia (especially in hospitalized patients—ventilator-associated pneumonia)
  - Meningitis (especially neonatal meningitis)
  - Wound and soft tissue infection such as cellulitis and infection of ulcers and wounds, especially in diabetic foot.
  - Osteomyelitis
  - Endovascular infection and bacteremia.

LABORATORY DIAGNOSIS *Escherichia coli*

- **Sample collection:** Depends on the site of infection—urine, stool, pus, wound swab etc
- **Direct smear:** Gram-negative bacilli, and pus cells
- **Culture:**
  - Blood agar: Circular, grey, moist colonies, hemolysis variable
  - MacConkey agar: Flat, pink LF colonies
- **Culture smear and motility testing:** Motile gram-negative bacilli
- **Biochemical identification:**
  - Catalase positive and oxidase negative
  - Nitrate is reduced to nitrite
  - ICUT tests: Indole(+), Citrate (–), Urease(–), TSI: A/A, gas(+), H_2S(–)
  - Sugar fermentation test: Ferments most sugars
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Diagnosis of UPEC and diarrheagenic *E. coli* has been described later under UTI and diarrhea.

- **Sample collection:** It depends on the site of infection (Table 29.5).
- **Direct smear of specimen by Gram staining:** *E. coli* is gram-negative, straight rod measuring 1–3 μm × 0.4–0.7 μm, arranged singly. Plenty of pus cells are also found in direct smear.
- **Culture:** *E. coli* is an aerobe and facultative anaerobe. It grows on ordinary culture media at optimum temperature of 37°C (ranges 10–40°C) in 18–24 hours. The culture media used are as follows:
  - **Blood agar:** Colonies are big, circular, grey, moist and occasionally β hemolytic (mainly UPEC strains)
  - **MacConkey agar:** Colonies are circular, moist, smooth with entire margin, **flat and pink** (due to lactose fermentation) (Fig. 29.1).
  - **Liquid medium,** such as peptone water broth-produces uniform turbidity.
- **Culture smear and motility testing:** Culture smear of the colonies shows gram-negative bacilli arranged singly. Hanging drop reveals motile bacilli (by peritrichate flagella).
- **Biochemical test:** Described below.

TABLE 29.5: Sample collection in *E. coli* infections

Specimens collected	Disease
Pus, exudates and wound swab	Cellulitis or wound infection
Urine	Urinary tract infections (UTI)
Stool	Diarrhea
Cerebrospinal fluid (CSF)	Meningitis
Peritoneal exudate	Peritonitis
Sputum	Pneumonia
Tracheal aspirate	Ventilator-associated pneumonia
Blood	Bacteremia

Fig. 29.1: Flat pink lactose fermenting colonies of *E. coli* on MacConkey agar (arrow showing)

***E. coli* shows the following Biochemical Properties**

- Catalase positive and oxidase negative
- Nitrate is reduced to nitrite
- **ICUT tests:**
  - Indole test: Positive (cherry red ring is formed)
  - Citrate test: Negative (citrate is not utilized)
  - Urease test: Negative (urea is not hydrolysed)
  - TSI (triple sugar iron agar) test: Shows acid/acid, gas present, H_2S absent
- **Sugar fermentation test:** *E. coli* ferments most of the sugars, such as glucose, lactose, mannitol, maltose (but not sucrose), with production of acid and gas.
- **MR** (methyl red) test: Positive
- **VP** (Voges-Proskauer) test: Negative

- **Antimicrobial susceptibility testing**: It is necessary to administer proper antibiotics.
  - It is done on Mueller-Hinton agar by using disk diffusion method.
  - *E. coli* can rapidly develop resistance to multiple drugs. Many strains of *E. coli* are producers of β lactamases such as ESBL (extended spectrum β lactamases) and MBL (metallo-β-lactamases).

Urinary Tract Infection (UTI)

E. coli (uropathogenic *E. coli* or UPEC) is the single most common pathogen, accounting for 70–75% of all cases of UTI. **UPEC** serotypes O1, O2, O4, O6, O7 and O75 are responsible for most UTIs.

Route of spread: *E. coli* reaches the urinary tract by two routes.

1. **Ascending route:** After colonizing the periurethral area, *E. coli* ascends the urinary tract to reach bladder resulting in cystitis and urethritis. Further ascension, leads to pyelonephritis.
2. **Descending route:** It is due to hematogenous seeding of *E. coli* into kidneys resulting in pyelonephritis.

Types: Depending on the site involved, there are two types of UTIs—1. lower UTI and 2. upper UTI (Table 29.6).

Predisposing factors that Promote UTI:

- **Females:** Due to short urethra and close proximity to anus, there is more chance of getting lower UTI than males.
- Presence of urinary catheters
- **Urinary obstruction:** As occurs in prostate enlargement or urinary stones; leads to urine stasis.
- **Pregnancy:** Physiological obstruction in urinary tract due to growing fetus may lead to prolonged stasis of urine. Asymptomatic bacteriuria (urinary infection without symptoms) is common in pregnant women.

TABLE 29.6: Differences between lower UTI and upper UTI

Characteristics	Lower UTI	Upper UTI
Site involved/ syndromes	Bladder (cystitis), and urethra (urethritis)	Kidney and ureter (pyelonephritis)
Symptoms	Local manifestations— Dysuria, urgency, frequency,	Local and systemic manifestations (such as fever, vomiting, abdominal pain)
Route of spread	Ascending route	Both ascending (common) and descending route
Occurrence	More common	Less common
Virulence factors of *E. coli*	Fimbriae (e.g. P fimbriae)	Capsular K antigen
Virulence factors of *E. coli* responsible for both upper and lower UTI: ▪ Cytotoxins (CNF 1: cytotoxic necrotizing factor 1 and SAT: Secreted autotransporter toxin) ▪ Hemolysins		

Laboratory Diagnosis of UPEC

Specimen Collection

- **Clean voided midstream urine:** It is the most common specimen for UTI; collected after properly cleaning the urethral meatus or glans.
- **Suprapubic aspiration** of urine from the bladder**:** It is the most ideal specimen. It is recommended for patients in coma or infants.
- In catheterized patients, urine should be collected from the catheter tube (after clamping and disinfecting); but not from the bag.

Transport

Urine sample should be processed immediately. If delay is expected for more than 1–2 hours, then it can be stored in refrigerator or stored by adding boric acid, glycerol or formate for maximum 24 hours.

Direct Examination

The screening tests done are as follows:

- **Wet mount examination:** It is done to demonstrate the pus cells in urine. Pyuria of more than 8 pus cells/mm^3 or 4 lakh pus cells excreted in urine/hour is taken as significant.
- **Leukocyte esterase test:** It is rapid and cheaper method, detects leukocyte esterases secreted by pus cells present in urine.
- **Nitrate reduction test (Griess test):** Nitrate reducing bacteria like *E. coli* give a positive result.
- **Catalase test:** *E. coli* and other bacteria that produce catalase enzyme give a positive result.
- **Gram staining** of urine is not a reliable indicator as—(1) the bacterial count in urine is usually low, (2) pus cells rapidly deteriorate in urine and may not be seen well. Gram staining may be limited to pyelonephritis and invasive UTI cases and a count of ≥ 1 bacteria/oil immersion field is taken as significant.

Culture

- **Culture media:** Urine sample should be inoculated onto MacConkey agar and blood agar or CLED agar (cysteine lactose electrolyte deficient agar).
- **Kass concept of significant bacteriuria:** This is based on the fact that, though the normal urine is sterile it may get contaminated during voiding, with normal urethral flora. However, the bacterial count in contaminated urine would be lower than that caused by an infection.
  - A count of **≥10^5 colony forming units (CFU)/mL** of urine is considered as significant—indicates infection (referred as 'significant bacteriuria' developed by Kass)
  - **Low count of** ≤10^4 CFU/mL is due to commensal bacteria (due to contamination during voiding and of no significance). However, low counts may be significant in the following conditions:
    - Patient on antibiotic or on diuretic treatment.
    - Infection with some gram-positive organisms such as *S. aureus* and *Candida*.
    - Pyelonephritis and acute urethral syndrome.
    - Sample taken by suprapubic aspiration.
- **Quantitative culture:** This is done to count the number of colonies. Each colony on plate corresponds to one bacterium in urine sample. Quantitation is done by—
  - Semi quantitative method such as standardized loop technique.
  - Quantitative method such as pour plate method.

Antibody Coated Bacteria Test

This test is done to differentiate upper and lower UTI.

- In **upper UTI**, as the route of spread is hematogenous, bacteria coated with specific antibodies are found in urine. Such bacteria coated with specific antibody are detected by immunofluorescence method using fluorescent labelled antihuman globulin.
- In **lower UTI**, bacteria found in urine are never coated with specific antibodies.

Diarrhea (Diarrheagenic E. coli)

Diarrheagenic *E. coli* are antigenically distinct from the commensal *E. coli* which colonize the intestine. Only few serotypes of *E. coli* which express the enterotoxin or other virulence mechanisms can cause diarrhea. There are six types of diarrheagenic *E. coli*.

Enteropathogenic E. coli (EPEC)

EPEC frequently causes **infantile diarrhea** (outbreaks) and occasionally cause sporadic diarrhea in adults. Person-to-person spread is seen.

- It is nontoxigenic and noninvasive.
- Mechanism of diarrhea:
  - **Adhesion** to intestinal mucosa, mediated by plasmid coded **bundle-forming pili**, which form cup-like projections called **pedestals**.
  - **A/E lesions** (attaching and effacing lesions): These are typical lesions produced on the intestinal epithelium (coded by chromosomal **LEE gene**, i.e. locus for enterocyte effacement); which leads to disruption of brush border epithelium causing increased secretion and watery diarrhea.

Enterotoxigenic E. coli (ETEC)

ETEC is the most common cause of **traveler's diarrhea** causing 25–75% of cases.

- It causes acute watery diarrhea in infants and adults.
- Common serotypes associated are—O6, O8, O15, O25, O27, O153, O159, etc.
- It is toxigenic, but not invasive.
- **Pathogenesis of ETEC is by:**
  - **Attachment** to intestinal mucosa is mediated by fimbrial protein called **CFA** (colonization factor antigen)
  - **Toxin production**—(1) heat-labile toxin or LT (acts by ↑cAMP), (2) heat-stable toxin or ST (acts by ↑cGMP).
- Diagnosis is done by detection of toxins by *in vitro* and *in vivo* methods (refer to Table 29.4).

Enteroinvasive E. coli (EIEC)

Common serotypes associated with EIEC are O28, O112, O114, O124, O136, O152, etc.

- **Pathogenesis:** EIEC is not toxigenic, but invasive. The epithelial cell invasion is mediated by a plasmid coded antigen called virulence marker antigen **(VMA)**.
- EIEC is biochemically, genetically and pathogenically closely related to *Shigella*.
- **Manifestations:** These include ulceration of bowel, dysentery (diarrhea with mucus and blood, called bacillary dysentery resembling shigellosis).
- **Diagnosis:**
  - Detection of VMA by ELISA
  - HeLa cell invasion assay
  - Sereny test (inoculation of bacterial suspension into guinea pig eyes produces conjunctivitis)
  - Compared with other *E. coli* strains, EIEC are biochemically atypical being nonmotile, lactose nonfermenters and negative for lysine decarboxylase.

Enterohemorrhagic E. coli (EHEC)

- **Serotypes** associated with EHEC are:
  - O157:H7 (most common serotype)
  - Other serotypes are rarely associated such as O26:H11, O6, O55, O91, O103, O111 and O113.
- EHEC is usually transmitted by contaminated food, i.e. consumption of lettuce, spinach, sprouts and undercooked **ground beef**.
- It is prevalent mainly in industrialized countries (in contrast to other diarrheagenic *E. coli* which are common in developing regions).
- **Low infective dose:** The infective dose of EHEC is very low. Only few organisms (<10^2 bacilli) are required to inititate the infection.
- **Pathogenesis:** EHEC secretes a toxin called **verocytotoxin** or **Shiga-like toxin** (refer Table 29.4 and the highlight box below).

Shiga-like Toxin

Mechansim of action: Shiga like toxin acts by inhibiting the protein synthesis by inhibiting the 28S subunit of 60S ribosome.

Shiga-like toxin is of two types—Stx1 and Stx2

- Stx1 is indistinguishable from shiga toxin produced by *Shigella dysenteriae* type 1.
- Stx2 is more commonly associated with development of HUS than Stx1.

- **Manifestations:** Shiga-like toxin has predilection for endothelial cells causing capillary microangiopathy which leads to:
  - **HC (hemorrhagic colitis):** It manifests as gross bloody diarrhea, abdominal pain and fecal leukocytosis but no fever.
  - **Hemorrhagic uremic syndrome (HUS):** It is characterized by injury to small vessels of the kidney and brain, which can lead to bloody diarrhea, thrombocytopenia, renal failure and encephalopathy but without fever. It is more common in children.
- **Diagnosis:**
  - **Sorbitol MacConkey agar:** EHEC, in contrast to other *E. coli*, does not ferment sorbitol and produces pale colonies.
  - **Rainbow agar:** O157 strains appear as black colonies on this medium as they are negative for β-glucuronidase.
  - **Toxin detection:**
    - Demonstration of cytotoxicity in Vero cell lines (gold standard method)
    - Fecal toxin detection by ELISA or rapid tests
  - **PCR** can be used to differentiate genes coding for Stx1 and Stx2.

Enteroaggregative E. coli (EAEC)

It is so named because it adheres to HEp-2 cells in a distinct pattern, layering of the bacteria aggregated in a stacked-brick fashion. Most strains are "O" untypeable but "H" typeable.

- **Pathogenesis:**
  - Intestinal colonization is mediated by aggregative adhesion fimbriae I (regulated by *aggR* gene).
  - It also produces **EAST 1 toxin** (entero-aggregative heat stable enterotoxin 1).
- **Manifestations:** Persistent and acute diarrhea are commonly seen; especially in developing countries.

***E. coli* O104: H4**
It is an enteroaggregative strain that has caused major outbreaks in Germany in 2011. One peculiar feature of this strain is, it produces Shiga-like toxin and can cause HUS.

Diffusely-adherent E. coli (DAEC)

It is characterized by:
- Ability to adhere to HEp-2 cells in a diffuse pattern.
- Expresses diffuse adherence fimbriae which contribute to the pathogenesis.
- DAEC is capable of causing diarrheal disease, primarily in children aged 2–6 years.

SHIGELLA

Shigella, the most important agent of bacillary dysentery, is named after Japanese microbiologist Kiyoshi Shiga who isolated the first member, *S. dysenteriae* serotype-1 (the *Shiga bacillus*) in 1896 from epidemic dysentery. Shigellae differ from *E.coli* being nonmotile and not fermenting most sugars except mannitol.

Classification

Based on a combination of biochemical and serological characteristics, shigellae are classified into four species—*S. dysenteriae, S. flexneri, S. boydii* and *S. sonnei* which are also designated as serogroups A, B, C and D respectively.

Antigens and Serotyping of *Shigella*

Based on somatic O polysaccharide antigen, *Shigella* species are further typed into four groups.

1. ***S. dysenteriae* (group A):** It has 15 serotypes. It does not ferment mannitol, in contrast to other species of *Shigella*, which are mannitol fermenters.
   - Serotype 1 (*S. shigae*) is the only *Shigella*, which produces Shiga toxin. It is the only member of family Enterobacteriaceae to be catalase negative. It is indole negative.
   - Serotype 2 (*S. schmitzi*) forms indole and ferments sorbitol and rhamnose.
   - Serotype 3–7 were formerly called Large-Sachs group.
2. ***S. flexneri* (group B):** Based on type specific antigen, it is further typed into 6 serotypes.
   - *S. flexneri* is the most complex species antigenically.
   - Serotype 6 is always indole negative and is further typed to three biotypes—Manchester, Newcastle and Boyd 88 based on gas production from sugars.
   - *S. flexneri* can also be typed by bacteriophage typing into 123 phage types.
3. ***S. boydii* (group C):** It has 19 serotypes. It was first described by Boyd. *S. boydii* is isolated least frequently from cases of bacillary dysentery.
4. ***S. sonnei* (group D):** It is antigenically homogeneous and has only one serotype. It can be typed by colicin typing into 26 colicin types.

Other Antigens of Shigellae

- K antigen may be present in some serotypes which may not be visible as capsule, but it covers the O antigen and makes it inagglutinable by homologous O antisera.
- Fimbrial antigens may be found in some strains, especially in *S. flexneri*.
- Flagellar H antigen is absent.
- Cross reactivity:
  - Antigens of many *Shigella* serotypes (other than *S. sonnei*) cross-react with serotypes of *E. coli*.
  - Antigens of *S. sonnei* cross react with *Plesiomonas shigelloides*.

Pathogenesis

Shigella is one of the important causes of bacillary dysentery.
- **Mode of transmission:** Infection occurs by ingestion through contaminated fingers (most common), food, and water or rarely flies. It can also be transmitted sexually (homosexuals).
- **Minimum infective dose:** As low as 10–100 bacilli are capable of initiating the disease, probably because of their ability to survive in gastric acidity.
- **Entry via M cell:** Bacilli enter the mucosa via M cells. They cross the basolateral side of M cells to reach the submucosa where they are engulfed by macrophages. Subsequently, the macrophages release bacilli. Cytokines are released by infected intestinal epithelial cells, which attract increased numbers of inflammatory cells to the infected site, exacerbating inflammation, and leading to the acute colitis that characterizes shigellosis.
- **Invasion:** Once inside the submucosa, shigellae induce their own uptake into the adjacent epithelial cells. Invasion is determined by a **large virulence plasmid** of 214 kb size, which codes for important virulence factors such as **ipa proteins** and **type III secretion system**. They inturn help in uptake of the shigellae into the host cells.
- **Direct cell-to-cell spread:** Shigellae spread directly from one host cell to the other by inducing actin polymerisation of host cells, mediated by ***IcsA*** proteins.
  - Actin filaments attach to one pole of the bacilli and form a tail. This helps in propelling the bacilli through the cytoplasm.
  - Once, the organisms come into contact with host cell membrane, cellular protrusions are formed and the bacilli are engulfed by neighbouring cells.

Contd...

Contd...

- **Exotoxins:**
  - ***Shigella* enterotoxin (ShET1 and 2)**
    - **ShET1** is structurally similar to cholera toxin and is found essentially in *S. flexneri* 2a.
    - **ShET2** is present in all *S. flexneri* isolates. It helps in iron uptake.
  - **Shiga toxin:** It is a cytotoxin, produced by *S. dysenteriae* type 1. It is structurally and functionally similar to verocytotoxin of EHEC. It inhibits protein synthesis by inhibiting 60S ribosome. It enhances local vascular damage of intestine as well as internal organs, such as kidney and brain.
- **Endotoxin:** It acts similar to any other gram-negative endotoxin and induces intestinal inflammation and ulcerations.

Clinical Manifestations

Shigellosis typically evolves through five phases:

1. **Incubation period:** It usually lasts for 1–4 days.
2. **Initial phase** is characterized by watery diarrhea with fever, malaise, anorexia and vomiting.
3. **Phase of dysentery:** It is characterized by frequent passage of bloody mucopurulent stools with increased tenesmus and abdominal cramps. Endoscopy shows an edematous and hemorrhagic mucosa, with ulcerations and overlying exudates. Most of the cases are self-limiting.
4. **Phase of complication:** It is commonly seen with children less than 5 years age.
   - **Intestinal** complications such as toxic megacolon, perforations and rectal prolapse.
   - **Metabolic** complications, such as hypoglycemia, hyponatremia, and dehydration.
   - **Ekiri syndrome** or toxic encephalopathy: It is a metabolic complication of shigellosis; manifests as altered consciousness, seizures, delirium, abnormal posturing and cerebral edema.
   - Bacteremia is rare and can lead to meningitis and pneumonia. Rarely, cases of vaginitis and keratoconjunctivitis have been reported.
5. **Postinfectious phase:** Patients expressing HLA-B27, develop an autoimmune reaction months after shigellosis; characterized by reactive arthritis, ocular inflammation and urethritis. It is seen only after *S. flexneri* infection (occurs in 3% of cases).

Epidemiology

Risk factors for shigellosis include overcrowding, poor hygiene and children less than 5 years.

- It tends to occur as epidemics in developing countries such as Indian subcontinent and sub-Saharan Africa.
- *S. flexneri* accounts for maximum number of cases (60%) in the developing areas including India, whereas *S. sonnei* is more prevalent in developed and industrialized world, accounting for 77% of cases.
- Cases caused by *S. dysenteriae* type-1 are associated with high mortality. It usually causes epidemics of dysentery, particularly in refugee camps.
- Humans are the natural host and cases are the only source of infection. Chronic carriage is rare except in malnourished children or AIDS patients.
- About 164.7 million cases of bacillary dysentery occur annually of which 163.2 million are in developed countries. Children (<5 years) accounts for 61% of the cases.
- With improved sanitation, the incidence of shigellosis is decreasing. However, the worrisome part of the present day is development of drug resistance among the *Shigella* strains.

LABORATORY DIAGNOSIS — ***Shigella* dysentery**

- **Specimen:** Fresh stool
- **Transport media:** Sach's buffered glycerol saline broth
- **Wet mount preparation:** Pus cells, erythrocytes
- **Culture**
  - Enrichment broth such as—Selenite F broth, tetrathionate broth and gram-negative broth
  - **Selective media such as:**
    - Mildly selective media, e.g. MacConkey agar- translucent NLF colonies
    - Highly selective medium, e.g. DCA, XLD agar and SS agar
- **Culture smear and motility testing:** Gram-negative bacilli and non-motile
- **Biochemical reactions:**
  - Catalase positive and oxidase negative (except *S. dysenteriae* type 1 which is catalase negative)
  - Nitrate is reduced to nitrite
  - **ICUT tests:** Indole (–), Citrate (–), Urease (–), TSI: K/A, gas (–), H_2S (–)
  - **Sugar fermentation test:**
    - Ferments glucose and mannitol (except *S. dysenteriae*)
    - Does not ferment lactose and sucrose (except *S. sonnei* which is a late fermenter for both lactose and sucrose).
- **Typing**
  - Slide agglutination test with specific antisera can differentiate between four *Shigella* species
  - Bacteriocin or colicin typing is done for *S. sonnei*
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

- **Specimen collection:** Fresh stool is collected. Rectal swabs are not satisfactory.
- **Transport media:** Specimens should be transported immediately. If delay is inevitable, specimens should be transported in a suitable medium, such as Sach's buffered glycerol saline.
- **Wet mount preparation** of feces shows large number of pus cells, erythrocytes and macrophages.

- **Culture:** To inhibit the commensals, fecal specimen is inoculated simultaneously into enrichment broth and selective media.
- **Enrichment broth** such as Selenite F broth, tetrathionate broth and gram-negative broth are used. Uniform turbidity appears in 24 hours, from which again subcultures are made onto selective media.
- **Selective media such as:**
  - **Mildly selective media:** On MacConkey agar, the growth appears as small (2 mm), circular, translucent and non-lactose fermenting pale or colorless colonies.
  - **Highly selective medium** contains higher concentration of bile salts as inhibitory agent.
    - **DCA** (Deoxycholate citrate agar): Colonies are similar to those on MacConkey agar-translucent and NLF (colorless) colonies.
    - **XLD agar** (Xylose lysine Deoxycholate): Colonies of *Shigella* appear red without black center. It is superior to DCA as it is less inhibitory to *S. dysenteriae* and *S. flexneri*.
    - **SS agar** (*Salmonella Shigella* agar)
    - **Hektoen enteric agar:** Colonies of *Shigella* appear green with color fading towards the periphery.
- **Culture smear and motility testing:** Gram stain of colonies reveal short, gram-negative bacilli measuring 1–3 μm × 0.5 μm. They are nonmotile, noncapsulated and non-sporing.
- **Biochemical reactions:** Biochemically *Shigella* is an organism of exceptions. *Shigella* species and their serotypes can be differentiated by an array of biochemical tests.
  - **Catalase:** All shigellae are catalase positive except *S. dysenteriae* serotype-1 and *S. flexneri* serotype-4a.
  - **Oxidase test** is negative for all species.
  - **Mannitol fermentation:** All species ferment mannitol except *S. dysenteriae*, Newcastle biotype of *S. flexneri* serotype-6 and rabaulensis biotype of *S. flexneri* serotype-4a.
  - **Lactose and sucrose fermentation:** Shigellae are lactose and sucrose non-fermenters except *S. sonnei* which is a late fermenter of both lactose and sucrose.
  - **Gas production:** All shigellae are **anaerogenic** (do not produce gas) except—Manchester and Newcastle biotypes of *S. flexneri* type 6.
  - **Indole production:** Though most shigellae do not produce indole, it is consistent with only *S. dysenteriae* serotype-1, *S. flexneri* serotype-6 and *S. sonnei*. For others, it is variable. *S. dysenteriae* serotype-2 is always indole positive.
  - All are urease and citrate negative.
  - TSI shows alkaline/acid, no gas and no H_2S.
  - **Decarboxylase test:** All shigellae are negative for lysine, arginine and ornithine except *S. sonnei* which decarboxylates ornithine.
  - ONPG test is negative for all shigellae, except *S. sonnei*.
- **Slide agglutination test:** Because of biochemical variations, identification of *Shigella* is always confirmed by slide agglutination with polyvalent antisera (genus specific). Then, the species identification can be done by using group specific antisera specific for serogroups A, B, C or D. Serotypes under each species are further detected by using type specific antisera.
- **Bacteriocin or colicin typing** is done for *S. sonnei*. This is based on ability of a strain to produce particular colicin which inhibits the growth of a set of selected indicator strains. There are 26 colicin types of *S. sonnei*.
- **Antimicrobial susceptibility testing** is done on Mueller Hinton agar by disk diffusion test.

TREATMENT ***Shigella***

Because of the prompt transmissibility, current recommendation is that every case of shigellosis should be treated with antibiotics.

- Ciprofloxacin is the drug of choice.
- Alternative drugs which are effective are ceftriaxone, azithromycin, pivmecillinam and some fifth-generation quinolones.
- Duration of treatment is about 3 days except for:
  - *S. dysenteriae* type 1 infection—5 days.
  - Infections in immunocompromized patients—7–10 days.
- Oral rehydration solution (ORS) should be started for correction of dehydration and nutrition should be started as soon as possible after the completion of initial rehydration.

Prevention

- Handwashing is the single most important measure. Handwashing after handling of children's feces and before handling of food is highly recommended.
- Stool decontamination (e.g. with sodium hypochlorite) has proven useful.
- No vaccine against shigellosis is currently available, though several clinical trials are being conducted.

TRIBE II: EDWARDSIELLEAE

Edwardsiella is a commensal in the gut of reptiles and fishes. Human infection is rare.

- *E. tarda* is the most frequently isolated species of *Edwardsiella* in clinical specimens. It is associated with septic shock, liver abscess and infections related to trauma and aquatic environment.
- *E. tarda* is so named because it is biochemically slow. It is motile and biochemical properties are similar to *E. coli* with some exceptions:
  - Ferments fewer sugars (only glucose and maltose) than *E. coli*
  - Non-lactose fermenter
  - Produces H_2S.

TRIBE III: SALMONELLEAE

Tribe Salmonelleae comprises of genus *Salmonella* which is discussed separately in detail in Chapter 30.

TRIBE IV: CITROBACTEREAE

Citrobacter species are mostly environmental contaminants isolated from water, soil, food and feces of man and animals.

They occasionally cause urinary tract, gallbladder and middle ear infections and neonatal meningitis (*C. koseri*).

Identification: *Citrobacter* species are motile, lactose fermenters like *E. coli*, but differ from the latter in being citrate positive and lysine decarboxylase negative. Various species can be differentiated by:

- *C. freundii*—indole negative and H_2S positive
- *C. koseri* (previously, *C. diversus)*—indole positive and H_2S negative
- *C. amalonaticus*—indole positive, H_2S negative and grows in KCN medium.

Some strains of *Citrobacter freundii* (formerly called **Ballerup-Bethesda** group) possess Vi antigen, which is antigenically similar to that of salmonellae and may lead to confusion in identification.

TRIBE V: KLEBSIELLEAE

The tribe Klebsielleae consists of genera *Klebsiella, Enterobacter, Hafnia* and *Serratia*. They differ from all other tribes being VP positive but MR negative.

KLEBSIELLA

Klebsiella species are usually found as commensals in human intestines and as saprophytes in soil. Genus *Klebsiella* has two species—*K. pneumoniae* and *K. oxytoca*. Similar to *E. coli, Klebsiella* species are also lactose fermenters; however, they differ in being non-motile and capsulated (possess capsular polysaccharide).

Pathogenesis

K. pneumoniae has three subspecies:

1. *K. pneumoniae* subspecies *pneumoniae:* It is the most pathogenic among all.
   - It is responsible for severe lobar pneumonia, urinary tract infections, meningitis (neonates), septicemia and pyogenic infections such as abscesses and wound infections.
   - It frequently colonizes the oropharynx of hospitalized patients and is a common cause of nosocomial infections. Most of the hospital strains are multidrug resistant.
   - Pneumonia tends to be destructive with production of thick, mucoid, brick red sputum. Some time, the sputum has a thin and currant jelly-like appearance.
   - Some strains can rarely cause diarrhea and have been shown to produce an *E. coli* like heat stable enterotoxin.
2. *K. pneumoniae* subspecies *ozaenae* is associated with **atrophic rhinitis** (or *ozena*), characterized by foul smelling nasal discharge. It is biochemically inactive.
3. *K. pneumoniae* subspecies *rhinoscleromatis* causes **rhinoscleroma**; a chronic granulomatous hypertrophy of the nose, prevalent in southeastern Europe, India and in Central America. It is biochemically inactive.

Laboratory Diagnosis

K. pneumoniae shows the following biochemical properties:

- **Gram staining:** *Klebsiella* is short, plump, straight gram-negative rods, about 1–2 µm × 0.5–0.8 µm in size.
- **Culture:** On MacConkey agar, it produces large dome shaped mucoid (due to capsule) sticky, pink color, lactose fermenting colonies (Fig. 29.2A).
- **Biochemical identification:** See the following box.

Biochemical Identification of *Klebsiella*

K. pneumoniae can be identified by the following properties.

- **ICUT test:**
  - Indole test: Negative
  - Citrate test: Positive (citrate is utilized)
  - Urease test: Positive (urea is hydrolyzed)
  - TSI (triple sugar iron agar test): Shows acid/acid, gas present, H_2S absent
- **Sugar fermentation test:** Ferments most of the sugars such as glucose, lactose, mannitol, maltose (but not sucrose), with production of acid and gas
- **VP** (Voges-Proskauer) test: Positive
- **MR** (methyl red) test: Negative

K. oxytoca is biochemically similar to *K. pneumoniae*, but differs from the latter by being indole positive.

ENTEROBACTER

Enterobacter species are similar to *Klebsiella* in most biochemical reactions (VP positive and lactose fermenter) but differs from the latter in being motile and ornithine decarboxylase positive.

- *E. aerogenes* and *E. cloacae* are the most commonly isolated species from the clinical specimens.
  - They are also widely distributed in water, sewage, soil and feces of healthy persons.
  - They are opportunistic pathogens, implicated in infected wounds and urinary and respiratory

tract infections and occasionally septicemia and meningitis.

- *E. asburiae* differs from other *Enterobacter* in being non-motile and VP negative. It has been isolated from blood, wound and feces.
- *E. sakazakii* strains are biochemically similar to *E. cloacae* except that they produce yellow pigment, do not ferment sorbitol and may give PPA test positive. They have been isolated from cases of neonatal meningitis and septicemia.

HAFNIA

H. alvei, the only species under genus *Hafnia,*which is rarely isolated from wounds, abscess, sputum, urine and blood.

- It is lactose non-fermenter and positive for lysine and ornithine decarboxylase.
- Like *Serratia,* the biochemical reactions are best reliable when tested at 30°C.

SERRATIA

The characteristic property of *Serratia* is production of a red non-diffusible pigment called **prodigiosin**, which is formed optimally at 30°C (Fig. 29.2B).

- *S. marcescens* is the medically most important species. Human infection with other species is rare.
- It is a saprophyte found in water, soil and food. It may grow in sputum after collection and makes the sputum red (due to pigment production). This condition is known as 'pseudohemoptysis.'
- *S. marcescens* is being increasingly reported in various **nosocomial infections**, such as meningitis, endocarditis, septicemia, urinary, respiratory and wound infections.
- The hospital strains are often non-pigmented and multiple drug resistant (produce AmpC β-lactamases)
- The biochemical properties of *S. marcescens* include:
  - Production of lipase, gelatinase and DNase
  - Resistant to colistin and cephalothin.

PANTOEA

Pantoea (Greek word, meaning-of all sources) has been isolated from diverse geographical and ecological sources. *P. agglomerans* was associated with a nationwide outbreak of septicemia due to contaminated intravenous fluid.

TRIBE VI: PROTEEAE

Tribe Proteeae comprises of three genera: *Proteus, Morganella* and *Providencia*.

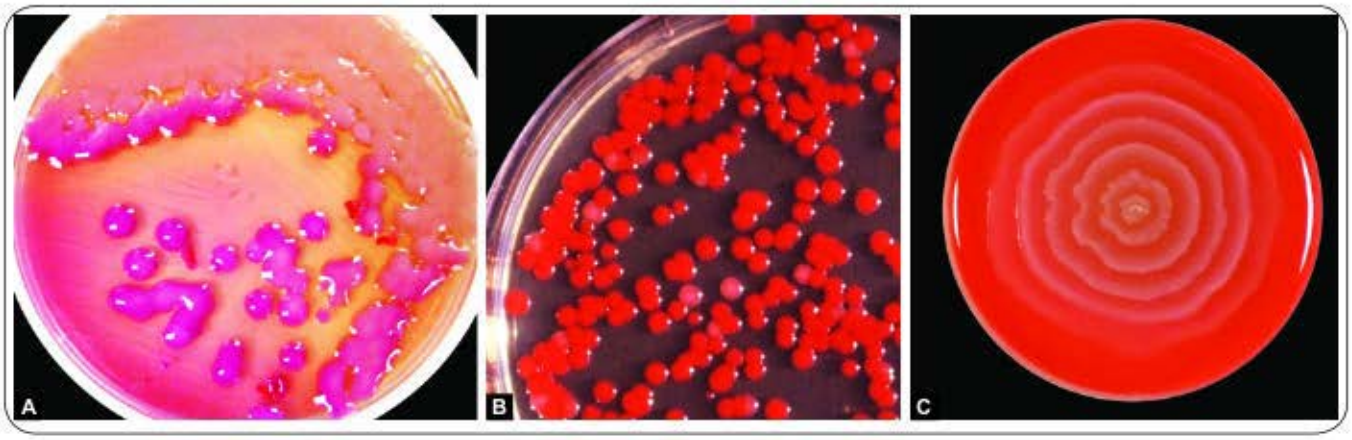
- **PPA positivity** is the unique tribe character of Proteeae. They produce an enzyme phenylalanine deaminase which converts phenylalanine to phenylpyruvic acid.
- All are motile and lactose nonfermenter.
- They have a fishy pungent odor.
- They are part of commensals in human intestine. However, they can cause nosocomial outbreaks of UTI, wound infections, etc.

PROTEUS

Historical Importance

Proteus species show pleomorphism, i.e. they vary in size. It is named after the Greek god 'Proteus' who was able to assume any shape.

Naming of H and O antigens: In general, the terms H and O antigens are used to denote the flagellar and somatic antigens of any organism respectively. However, the



Figs 29.2A to C: A. *Klebsiella* on MacConkey agar (Mucoid dome-shaped pink-colored colonies); **B.** *Serratia marcescens* (red-colored colonies); **C.** Swarming growth of *Proteus* on blood agar

Source: B. Wikimediacommons/Brudersohn *(with permission)*

naming of these antigens were linked historically to the properties of *Proteus*.

- The H antigen is named from the ability of flagellated strains of *Proteus* to grow on agar as a thin film resembling the film of breath on glass (from Greek word '*Hauch*', meaning 'film of breath').
- Naming of O antigen: The thin film is not observed when strains carrying only the somatic antigen (non-flagellated strains) grow on media (from Greek word '*Ohne Hauch*' meaning 'without film of breath').

Pathogenesis

Proteus mirabilis and *P. vulgaris* are the most commonly encountered species.

- **Saprophytes:** Most of the species are widely distributed in nature and are isolated from decomposing animal matter, sewage and soil.
- **Commensals:** They are also frequently present on the moist areas of the skin, intestine of humans and animals.
- **Infections produced:** They are opportunistic pathogens, commonly associated with urinary, wound and soft tissue infections and septicemia.
  - *Proteus* species are often involved in nosocomial outbreaks.
  - **Struvite stones in bladder:** *Proteus* produces urease enzyme, which breaks down urea to form ammonia that damages the renal epithelium and makes the urine alkaline. Alkaline urine predisposes to the deposition of phosphate, which leads to the formation of renal calculi.
  - Other *Proteus* species such as *P. penneri* and *P. myxofaciens* are rarely encountered in clinical specimens.

Proteus as the basis of Weil–Felix Reaction

Somatic antigen of certain non-motile *Proteus* strains (called **X strains**) cross react with the alkali-stable antigen of some *Rickettsia* species.

- Thus, *Proteus* antigens can be used to detect heterophile antibodies in sera of patients suffering from rickettsial infections.
- Three non-motile *Proteus* strains: OX2, OX19 (from *P. vulgaris*) and OXK (from *P. mirabilis*) are used in this agglutination test.

Laboratory Diagnosis

- **Pleomorphism:** *Proteus* species are gram-negative coccobacilli occasionally appear bacillary and in filamentous forms.
- **Odor:** They produce characteristic putrid fishy or seminal odor in cultures.
- **Swarming:** *Proteus* has an ability to swarm (or spread) on solid media (see Fig. 29.2C).

Swarming

The swarming of *Proteus* on solid media (e.g. blood agar) appears in two patterns:

- Uniform film of growth extended on the whole plate (continuous swarming)
- Concentric circles of growth surrounding the point of inoculum (discontinuous swarming) (Fig. 29.2C)

Mechanism of swarming: At the margin of a colony, the sparsely flagellated, short (2–4 µm) vegetative cells of *Proteus* become multinucleated, densely flagellated, nonseptate, elongated cells of 20–80 µm in length, known as a **swarm cells**.

- Swam cells have a property to migrate to surrounding uninoculated areas resulting in spreading of the colonies.
- This transition from vegetative cells to swam cells takes place when the cells receive a number of extracellular and intracellular signals.

Common problems in the laboratory: When mixed growth is present in the culture plate, swarming of *Proteus* overgrows other bacterial colonies. Hence, swarming is a common problem in the laboratory in isolating other bacterial colonies which are present along with *Proteus* swarming. Several methods have been used to inhibit swarming:

- Increased agar concentration to 6%.
- Incorporation of alcohol, boric acid, chloral hydrate, sodium azide, sulphonamide, surface active agents, etc.
- Swarming does not occur on MacConkey agar, CLED agar and phenyl ethyl agar.

Organisms exhibiting swarming:

- Swarming is seen only with *P. mirabilis* and *P. vulgaris* but not with other members of tribe Proteeae.
- Swarming can also be observed in other bacteria, such as *Serratia marcescens*, *Vibrio parahaemolyticus* and *Clostridium tetani*.

Biochemical properties

Both *P. mirabilis* and *P. vulgaris* (Table 29.3) are:

- Urease positive
- Citrate variable
- TSI shows alkaline/acid, gas present and H_2S present.
- MR positive but VP negative.

However, *P. mirabilis* and *P. vulgaris* can be differentiated by:

- Indole test—positive for *P. vulgaris*, negative for *P. mirabilis*
- Ornithine decarboxylase test—positive for *P. mirabilis*, negative for *P. vulgaris*.

Typing of *Proteus* can be done by:

- Bacteriocin typing
- Bacteriophage typing
- Ribotyping
- Dienes phenomenon (see below).

Dienes phenomenon: When two strains of *Proteus* are inoculated at different areas on a culture plate:

- If swarming of two strains merge incompletely, and remain separated by a narrow line of demarcation—indicates two strains are different
- If swarming of two strains merge completely without any line of demarcation—indicates two strains are identical.

MORGANELLA

Morganella has only one species, *M. morganii.*

- It is commonly found in human and animal feces.
- It is rarely associated with urinary tract infection, pneumonia and wound infection. Most of the infections are nosocomial.
- It does not swarm in culture. It is indole and urease positive but citrate negative (Table 29.3).
- TSI shows alkaline/acid, gas present but no H_2S.

PROVIDENCIA

Providencia species are associated with nosocomial infections of the urinary tract, wounds and burns.

It consists of five species; *P. rettgeri, P. stuartii, P. alcalifaciens, P. rustigianii* and *P. heimbachae.*

- *P. rettgeri* and *P. stuartii* are common pathogens. *P. alcalifaciens* has been proposed to cause diarrhea, but not proved.
- They are motile but do not show swarming. Common biochemical properties are shown in Table 29.3.

TREATMENT **Tribe Proteeae**

Members of tribe Proteeae are often multidrug resistant. They are also resistant to many disinfectants.

- They show intrinsic resistance to nitrofurantoin, tetracycline and polymyxin.
- They produce various β lactamases such as extended spectrum β lactamases (ESBL) and AmpC β-lactamases. As a result, they are resistant to most of the β-lactam drugs.
- Drug of choice depends on the antimicrobial susceptibility testing. In general, aminoglycosides and quinolones are effective in treatment.
- In general, *P. mirabilis* is more susceptible to antibiotics.

TRIBE VII: YERSINIEAE

The tribe Yersinieae comprises of genus *Yersinia* which contains three well-established human pathogens.

- *Yersinia pestis:* It is responsible for rodent-borne zoonotic disease called **plague**.
- *Yersinia pseudotuberculosis* and *Y. enterocolitica*—both cause **yersiniosis**, a self-limiting gastrointestinal illness that may occasionally have serious complications in special circumstances.

YERSINIA PESTIS

Yersinia pestis was isolated for the first time by Alexandre Yersin in 1894 in Hong Kong.

- It is the agent of plague, a fulminant systemic zoonosis, transmitted from rodents by arthropod vector (the rat flea).

TABLE 29.7: Biotypes of *Y. pestis* and associated pandemics

Biotypes	Nitrate reduction	Glycerol fermentation	Pandemics associated
Medievalis	–	+	First pandemic Justinian, AD541
Antiqua	+	+	Second pandemic Black death, Europe (1347–52)
Orientalis	+	–	Third pandemic (1894–1918) Hong Kong, China, India

- *Y. pestis* is gram-negative oval coccobacillus, often shows **bipolar staining** (ends of the bacilli stain darker than the central part) and pleomorphism (variable size and shapes) in older cultures. It is non-motile and capsulated.

Epidemiology of Plague

Plague is the one of the greatest killer known to mankind.

Plague Pandemics

There were three pandemics reported in the history, each was associated with a different biotype of *Y.pestis*, differentiated by glycerol fermentation and nitrate reduction (Table 29.7).

- First pandemic (in AD541): It occurred in the period of Roman Emperor Justinian.
- Second pandemic (in 14th century) was called **black death**, which had killed up to one-third of the European population.
- Third pandemic (1894): It started in Hong Kong. It mainly affected India and China causing more than 10 million deaths by 1918.

Timeline of Plague in India

- **1896 to 1918:** Hong Kong pandemic entered India and millions of people were killed.
- **1918 to 1967:** Plague gradually declined, occasional cases continued to be reported from endemic foci.
- **1967 to 1994:** No plague cases were reported
- **1994 (Surat epidemic):** It started as bubonic plague from Beed-Latur belt in Maharashtra. But, it soon became pneumonic plague and spread to Surat and adjoining regions of Gujarat. More than 6000 suspected plague cases with 60 deaths were reported over a period of two months (August-September 1994).
- **In 2002 (Shimla outbreak):** A short outbreak occurred at Rohru, near Shimla. Four deaths were reported.
- **In 2004 (Uttarkashi outbreak):** Localized outbreak of bubonic plague (8 cases and 3 deaths) was reported from Dangud village of Uttarkashi district, Uttaranchal.

- **Four potential endemic foci** are there in India at present which include—(1) region near Kolar, Karnataka (2) Beed-Latur belt in Maharashtra, (3) Rohru in Himachal Pradesh, and (4) Dangud village, Uttaranchal.

Current Situation in World

- Over five years (2004 to 2009), a total of 12,503 cases were reported (with 843 deaths) worldwide, mainly confined to 16 countries of Africa, Asia and America.
- Africa accounts for highest number of cases (97%) worldwide.

Epidemiological Factors

- **Reservoir:** Wild rodents, such as gerbils (*Tatera indica*), field mice and the bandicoot found in forests are the main reservoirs of infection in India than the domestic rats *Rattus rattus* as once thought.
- **Source of infection** are infected wild rodents, rat fleas and cases of pneumonic plague.
- **Vector:** Rat flea is the commonest vector of *Y. pestis*, which acquires infection by feeding on infected wild rodents.
  - Several species of rat flea may act as vectors such as *Xenopsylla cheopis* (the most efficient vector, found in north India) and *Xenopsylla astia* (less efficient, found in south India) and *Xenopsylla brasiliensis*.
  - Human flea (*Pulex irritans*) may rarely serve as vector.
- **Plague cycles:** Plague exists in two natural cycles:
  1. Domestic cycle: It occurs between humans, rat fleas and rodents.
  2. Wild or sylvatic cycle: It occurs in nature among wild rodents, independent of human beings.
- **Mode of transmission:** Human plague is frequently contracted from:
  - Bite of an infected rat flea (most common)
  - Direct contact with tissues of infected animal (rodents)
  - Droplet inhalation (man to man) from cases of pneumonic plague
  - Bite of an infected human flea (*Pulex irritans*).
- **Blocked flea:** In a blood meal, the fleas suck about 0.5 ml blood containing 5000 bacilli from infected rodents.
  - In the gut of the flea, the bacilli multiply enormously and may block the proventriculus. Such blocked flea eventually dies as it cannot obtain a blood meal.
  - However, while making efforts to suck, it regurgitates the blood mixed bacteria into the bite, thus transmitting the infection.
  - Infection may also be transmitted by contamination of the bite wound with the feces of infected fleas.
  - A partially blocked flea is more dangerous than a completely blocked flea as it survives longer inside burrows, may be up to 4 years in certain species.
  - **Extrinsic incubation period** is the interval between the flea acquiring infection through blood meal and becoming a blocked flea; which is usually about two weeks for *Xenopsylla cheopis*.
- **Cheopis index** (Average number of *X. cheopis* per rat) is the most significant flea index. Plague outbreak is likely to occur in places having cheopis index of more than 1.
- **Seasonality:** Plague is seasonal in north India (September to May). However, in South India, it occurs throughout the year which may be attributed to the climatic conditions of South favoring the rodents to breed.

Virulence factors of *Y. pestis* (Table 29.8)

- **Fraction 1 (F1) antigen:** It is a plasmid (pFra) encoded heat labile capsular protein antigen. It is expressed at 37°C or inside human body. It inhibits macrophage phagocytosis. It is highly antigenic and is used as immunodiagnostic marker of infection.
- **Phospholipase D/*Yersinia* murine toxin (Ymt):** It promotes *Y. pestis'* survival in the midgut of the infected flea.
- **Surface proteases (*Pla* gene-encoded):** They activate mammalian plasminogen and also degrade complements. They adhere to the extracellular matrix component laminin, thus promoting *Y. pestis* to disseminate from the site of inoculation.
- **pH 6 antigen:** It is a fibrillar surface protein, binds to host lipoproteins.
- **Lipopolysaccharide:** It possesses endotoxin activity.
- **Pigmentation:** Virulent strains produce brown colonies on hemin-containing media by storing hemin in the outer membrane. Pigments promote biofilm formation and is essential for flea blocking by *Y. pestis*.
- **Low calcium response plasmid:** It codes for type III secretion system (which injects F1 proteins into the host cells) and adhesins (help in attachment).
- **Siderophore:** It helps in acquisition of iron and reduces production of reactive oxygen species by phagocytes, thereby decreasing bacterial killing.

TABLE 29.8: Virulence factors of yersiniae

Yersiniae	Virulence antigens
Common to all *Yersinia*	Lipopolysaccharide
	Pigmentation
	Low calcium response plasmid
	Siderophore
Y. pestis-specific	Fraction 1 (F1) antigen
	Phospholipase D/murine toxin
	Surface proteases
Y. pestis and *Y. pseudotuberculosis*	pH 6 antigen
Y. enterocolitica and *Y. pseudotuberculosis*	Inv protein
	Ail protein
	Yersinia adhesin A (YadA)
Y. enterocolitica-specific	Myf antigen
	Heat stable toxin (ST toxin)
Y. pseudotuberculosis-specific	Super antigen mitogen

Human Plague: Clinical types

Human plague occurs in three clinical forms—(1) bubonic (most common form), (2) pneumonic and (3) septicemic.

Bubonic Plague

It is the most common type, transmitted by the bite of an infected rat flea.

- Bacilli pass through the local lymphatics to reach the regional lymph nodes, where they multiply.
- Incubation period is about 2–7 days.
- The onset is sudden and is characterized by fever, malaise, headache and painful lymphadenitis.
- **Buboes:** Regional lymph nodes appear as tense, tender swellings called buboes; the most common site being inguinal (Fig. 29.3A), but can also be crural, axillary, cervical, or submaxillary, depending on the site of the bite. Children are most likely to present with cervical or axillary buboes.
- Bubonic plague cannot spread from person to person as the bacilli are locked up in buboes.
- Without treatment, dissemination occurs leading to pneumonia (secondary) and meningitis.

Pneumonic Plague

Primary pneumonic plague results from inhalation of bacilli in droplets expelled from another person or an animal with plague pneumonia.

- Incubation period is short, about 1–3 days.
- The onset is sudden and is characterized by fever, headache and respiratory symptoms (productive cough or hemoptysis, dyspnea, and chest pain).
- Though pneumonic plague is rare (<1%), it is highly infectious and highly fatal.
- Agent of bioterrorism—aerosolized *Y. pestis* is a possible source of bioterrorism attack, especially in non-endemic regions.

Septicemic Plague

- Primary septicemic plague is rare except for accidental laboratory infections.
- Secondary septicemic plague is more common. It develops from spread of bubonic or pneumonic plague.
- Incubation period is about 2–7 days.
- Massive involvement of blood vessels results in hemorrhages in the skin and mucosa which may lead to gangrene of the affected site; hence disease was named in the past as **black death** (Fig. 29.3B).

Laboratory Diagnosis

Specimen Collection

Depending upon the type of plague, the specimens collected are:

Figs 29.3A and B: Plague manifestations. **A.** Swollen inguinal lymph node (bubo); **B.** Gangrene of the toes turned the dead digits black (black death)

Source: Public Health Image Library, A) ID#2044, B. ID#16550, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Bubonic plague—pus or fluid aspirated from buboes
- Pneumonic plague—sputum and blood
- Septicemic plague—blood and splenic aspirate (post mortem)

Transport medium (e.g. Cary-Blair medium) can be used if delay in transportation is expected.

Direct Microscopy

- **Gram staining:** Reveals presence of pus cells and gram-negative oval coccobacilli with rounded ends surrounded by capsule.
- **Wayson stain** or methylene blue staining demonstrates the typical **bipolar** or **safety pin** appearance. Two ends are darkly stained with clear central area (Fig. 29.4).

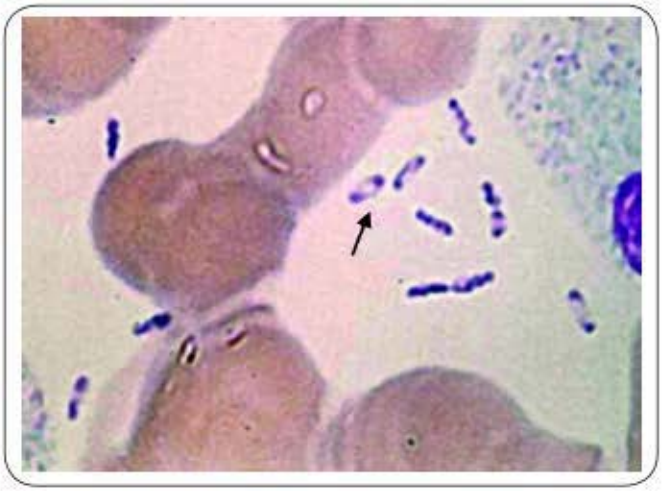


Fig. 29.4: Wayson staining demonstrates bipolar appearance of *Yersinia pestis* (*arrow showing*)

Source: Centers for Disease Control and Prevention (CDC) Atlanta, USA (*with permission*)

Culture

Y. pestis is aerobic and facultatively anaerobic. The optimum temperature for growth (unlike most pathogens) is **27°C** but the capsule develops best at **37°C**. It is not fastidious and grows on ordinary media. Various media used are as follows.

- **Blood agar:** Colonies are non hemolytic and ***dark brown*** pigmented due to the absorption of the hemin pigment.
- **MacConkey agar:** Lactose non-fermenting colorless colonies are formed
- **Nutrient broth:** Granular turbidity occurs with surface pellicles formed later.
- Nutrient broth with **oil** or **ghee** floated on top-characteristic **stalactites-like growth** occurs hanging down from the under surface of the oil.
- *Yersinia*-specific **CIN agar** (cefsulodin, irgasan, novobiocin): It is a selective medium, useful for culture of specimens containing normal flora, e.g. sputum.

Culture Smear and Motility Testing

- Gram staining of culture smear reveals **pleomorphism**-coccid, coccobacillary, bacillary, filamentous and giant forms. Involution forms are seen in older cultures.
- *Y. pestis* is nonmotile both at 25°C and 37°C; in contrast to other *Yersinia* species which are motile at 25°C and nonmotile at 37°C.

Biochemical Reactions

Y. pestis shows the following reactions:

- **Sugar fermentation:** It ferments glucose, mannitol and maltose with the production of acid but no gas. Lactose and sucrose are not fermented.
- It is catalase positive, oxidase negative.
- Indole, urease and citrate tests are negative.
- MR positive, but VP test is negative.
- Biotyping is done based on glycerol fermentation and nitrate reduction (Table 29.7).

F1 Antigen Detection

It may be detected from bubo aspirate or sputum by direct immunofluorescence test, ELISA or immunochromatographic test (ICT) by using monoclonal antibodies.

Antibodies to F1 Antigen Detection

Antibodies may be detected by passive hemagglutination or complement fixation test or ELISA.

- Antibodies have a limited diagnostic value as they appear late. Only a retrospective diagnosis can be made if fourfold rise of titer is noted.
- However, antibodies are useful epidemiological markers, as they remain positive for several years.

Molecular Methods

PCR is available targeting gene coding F1 antigen, *pesticin* gene, and the *plasminogen activator* gene.

Animal Inoculation

It is carried out by using Guinea pigs or white rats.

TREATMENT — ***Yersinia pestis***

Early start of antibiotics is crucial for reducing mortality.

- Streptomycin has been the choice of treatment for plague in the past, given for 10 days.
- Gentamicin is superior to streptomycin and currently recommended for treatment.
- Alternative drugs, such as doxycycline and chloramphenicol are also effective.
- β-lactams and macrolides are generally not recommended as the response is poor.

Prevention of Plague

Prevention and control of plague involves:

- Control of cases by early diagnosis, isolation and treatment of cases
- Control of fleas by use of effective insecticides, such as DDT or BHC (β-hexachloro-cyclohexane)
- Control of rodents
- **Chemoprophylaxis** should be given to all contacts of pneumonic plague. Doxycycline (100 mg twice a day) or tetracycline (500 mg 6 hourly) is the drug of choice, given for 7 days.
- **Vaccine:** WHO recommends using vaccine only for prevention of an anticipated outbreak and not for general use.
  - **Formalin killed vaccine** (Sokhey's modification of original Haffkine vaccine): It is prepared in Haffkine institute, Mumbai.
    - It is given subcutaneously, two doses 4 weeks apart and a booster given after 6 months. It is contraindicated in infants <6 months.
    - Protection is short-lasting (<6 months).
    - It is not protective against pneumonic plague and has considerable side effects
  - **Live attenuated vaccine** based on strain EV76 is still used in countries of the former Soviet Union but has significant side effects.
  - **Subunit recombinant F1** (rF1) vaccine is under trial.

Plague in Rodents

Plague is primarily a disease of rodents in which man becomes accidently involved. The plague bacillus is naturally parasitic in rodents and the disease spreads among rodents by rat fleas. When a diseased rat dies (rat fall), the fleas leave the carcass and, in the absence of another rat, may bite human beings, causing bubonic plague. Plague in rodents is similar to that in man. The disease is mild or inapparent in resistant species.

YERSINIOSIS

Yersiniosis is a zoonotic infection caused by enteropathogenic *Yersinia* species, i.e. *Y. enterocolitica* or *Y. pseudotuberculosis*.

- Pigs and other wild and domestic animals are the usual hosts.
- Human infection occurs due to consumption of contaminated food such as raw pork, milk, etc.
- Yersiniosis is most common in childhood and in colder climates.
- Patients present with abdominal pain and sometimes with diarrhea.

Geographical Distribution

- *Y. enterocolitica* is found worldwide, most commonly in northern Europe and America.
- Outbreaks of *Y. pseudotuberculosis* are generally rare, have been reported from Finland.

Serogrouping

- *Y. enterocolitica* is further characterized biochemically (six biotypes) and antigenically (60 serotypes, based on somatic O antigen). Worldwide, most clinical infections are associated with serogroups O:3 and O:9.
- *Y. pseudotuberculosis* can be further differentiated into six serotypes (1 to 6) based on somatic O and flagellar H antigens.

Virulence Factors

There are several groups of virulence factors such as:

- **Virulence factors common to both the species**:
  - Invasin (Inv) protein: It binds to β-1 integrins on M cells of GI mucosa which helps in invasion.
  - Ail protein (attachment and invasion locus): It helps in attachment, invasion and inactivates complements.
  - *Yersinia* adhesin A (Yad A)—(1) it binds to extracellular matrix proteins, such as collagen and fibronectin and helps in invasion, (2) inactivates complements.
- ***Y. enterocolitica* specific virulence factors:**
  - Myf antigen is a fimbrial antigen, helps in adhesion.
  - Heat-stable toxin: Similar to that of *E. coli*, produced only at temperature <30°C.
  - pH6 antigen: Fimbrial surface protein, helps in adhesion. It is also expressed by *Y. pestis*.
- ***Y. pseudotuberculosis* specific virulence factors:**
  - Super antigen—binds to T cells non-specifically leading to massive cytokine release.
- **Virulence factors common to all yerisiniae:** Such as LPS, pigments, siderophores and low calcium response plasmid (described earlier in Table 29.8).

Clinical Manifestations

Overall, *Y. enterocolitica* is more frequently reported clinically than *Y. pseudotuberculosis*.

- **Self-limited gastroenteritis** (diarrhea with or without blood) occurs in younger children.
- **Intestinal complications** occur in older children, characterized by terminal ileitis (mostly in *Y. enterocolitica*) and mesenteric adenitis. Patients present with acute pain abdomen, may mimic ***pseudoappendicitis***.
- **Septicemia:** It is seen typically in adults, characterized with fever and leukocytosis. It usually occurs in patients with coexisting diabetes mellitus, liver disease and iron overload.
- **Post infective phenomena** (in adults) occurs commonly with *Y. enterocolitica*. It occurs as a result of autoimmune activity, initiated by the deposition of bacterial non-viable components in joints and other sites. Manifestations include:
  - *Reactive arthritis*—mostly associated in persons positive for HLA-B 27.
  - *Erythema nodosum:* It occurs independently without any link to HLA-B 27 phenotype.
  - *Graves' disease*—*Y. enterocolitica* contains an antigen similar to thyroid-stimulating hormone (TSH) binding site. However, whether this cross-reactivity has any significant role in Graves' disease remains unclear.
- **Super antigen:** Some strains of *Y. pseudotuberculosis* express a super antigen **mitogen**, which has caused scarlet-like fever in Russia, similar illness in Japan (**Izumi-fever**) and has been linked to the pathogenesis of idiopathic acute systemic vasculitis of childhood called **Kawasaki's disease**.

Laboratory Diagnosis

Culture Isolation

- **For isolation from blood:** Blood culture bottles (BHI broth) should be used.
- **For isolation from lymph nodes aspirate:** Culture is done on conventional media (blood agar, nutrient agar and MacConkey agar).
  - **Blood agar:** They produce granular translucent colonies with a beaten copper surface, non-hemolytic colonies.
  - **MacConkey agar:** Growth of *Y. pseudotuberculosis* is poor. *Y. enterocolitica* grows well and produces lactose non-fermenting pale colonies.
- **For isolation from feces, food or soil:** Selective media should be used, such as:
  - Deoxycholate citrate agar
  - MacConkey agar
  - **Yersinia CIN agar** (Cefsulodin-irgasan-novobiocin): Typical **dark red bull's eye** appearing colonies are formed in 24 hours.
- **Incubation:** Plates should be incubated at 25°C and 37°C to differentiate from most of the other pathogens which grow only at 37°C.
- **Cold enrichment** can also be done by incubating in phosphate-buffered saline at 4°C for 3 weeks.

Biochemical Tests

Y. enterocolitica and *Y. pseudotuberculosis* show the following properties by which they can be differentiated from *Y. pestis*:

- **Differential motility:** They are motile at 22°C (but not at 37°C).
- **Cold enrichment:** Growth improves on refrigeration (4°C).
- Urease positive

Tests to differentiate *Y. enterocolitica* from *Y. pseudotuberculosis* include:

- Sugar fermentation
  - Sucrose, cellobiose and sorbitol are fermented only by *Y. enterocolitica*
  - Rhamnose, salicin and melibiose are fermented only by *Y. pseudotuberculosis*
- Ornithine decarboxylase-positive only for *Y. enterocolitica.*
- VP test is positive only for *Y. enterocolitica.*

Serology

Antibodies can be detected by agglutination or ELISA using serotype specific O-antigen types. In *Y. pseudotuberculosis* infection, antibodies appear early during acute phase of illness; whereas *Y. enterocolitica* specific agglutinating antibodies are more likely to be found in convalescent sera.

TREATMENT **Yersiniosis**

Most cases of diarrhea are self-limiting. Treatment is required only for systemic infections such as in case of septicemia.

- Fluoroquinolone (ciprofloxacin) or third-generation cephalosporins (cefotaxime) are effective.
- *Y. enterocolitica* strains nearly always produce β-lactamases but not *Y. pseudotuberculosis* strains.

TRIBE VIII: ERWINIEAE

Tribe Erwinieae comprises of genus *Erwinia*. The *Erwinia* species are primarily plant pathogens and are also saprophytes in soil. *E. persicinus* had occasionally been isolated from urinary infections in hospitalized patients.

NEWLY INCLUDED GENERA

Based on DNA hybridization studies, several new genera are recently included in the family Enterobacteriaceae such as:

- ***Klebsiella granulomatis*** (previously, *Calymmatobacterium granulomatis*): It is the agent of sexually transmitted disease called **granuloma inguinale** or **donovanosis**. It is described in detail in Chapter 36.
- ***Plesiomonas:*** It is an oxidase positive, motile fermenting gram-negative bacillus, previously classified under Vibrionaceae family.
  - *P. Shigelloides* is the only species. It is so named because it is antigenically related to *S. sonnei.*
  - However, it differs from *Shigella* in being positive for oxidase, utilizes lysine, arginine and ornithine and is motile with polar lophotrichous flagella.
  - It is the only member of Enterobacteriaceae which is oxidase positive.
  - It is found as saprophyte in water and soil, and also as a commensal in animal and rarely in human intestine.
  - Human infection: It rarely causes gastroenteritis which may be severe in immunocompromised patients. Extraintestinal manifestations include rare cases of meningitis, septicemia, cellulitis and septic arthritis.
- **Other new genera include:** *Ewingella, Buttiauxella, Budvicia, Cedecea, Kluyvera, Rahnella* and *Tatumella*.

EXPECTED QUESTIONS

I. Essays:

1. List the diarrheagenic *Escherichia coli*. Discuss the pathogenesis and laboratory diagnosis of diarrheagenic *E. coli*.
2. A 24-year-old female was admitted with fever, dysuria and frequency of micturition for the past 3 days. Urine microscopy revealed pyuria.
   a. What is the clinical diagnosis of this condition?
   b. Which is the most common etiological agent for this condition?
   c. What are the various methods to collect the specimen?
   d. Describe the laboratory diagnosis of this condition in detail?

II. Write short notes on:

1. *Klebsiella pneumoniae*
2. Pathogenesis of shigellosis
3. Virulence factors of *Yersinia pestis*
4. Laboratory diagnosis of plague

III. Multiple Choice Questions (MCQs):

1. Traveler's diarrhea is caused by:
a. ETEC b. EHEC
c. EPEC d. EIEC

2. Culture media used for diagnosis of EHEC O157: H7 is:
a. O7 culture b. Sorbitol MacConkey media
c. XLD agar d. Deoxycholate media

3. Most common cause of community-acquired urinary tract infection is:
a. *E. coli* b. *Proteus*
c. *Pseudomonas* d. *Klebsiella*

4. Phenyl alanine deaminase test is characteristic of which of the following tribes of Enterobacteriaceae:
a. Escherichieae b. Salmonelleae
c. Yersinieae d. Proteeae

5. Which of the following *Shigella* species is mannitol nonfermenter?
a. *S. sonnei* b. *S. boydii*
c. *S. dysenteriae* d. *S. flexneri*

6. Plague is transmitted by:
a. Rat flea b. Soft tick
c. Hard tick d. Louse

7. Bipolar staining is characteristic of:
a. *Yersinia pestis* b. *Shigella*
c. *Klebsiella* d. *Proteus*

Answers

CHAPTER 30

Enterobacteriaceae II: Salmonella

Chapter Preview

- Classification and nomenclature
- Typhoidal salmonellae
- Non-typhoidal salmonellae

Diseases caused by various members of the genus *Salmonella* are extremely important public health problems worldwide. The credit of discovery of '*Salmonella*' goes to Salmon and Smith (1885).

The most important member of the genus is *Salmonella* Typhi, the causative agent of typhoid fever. It was first observed by Eberth (1880) and Gaffky (1884) and hence was formerly called Eberth-Gaffky bacillus or *Eberthella typhi*.

CLASSIFICATION AND NOMENCLATURE

Salmonella is antigenically complex. The classification and nomenclature of salmonellae have undergone several modifications over the past years. There are several classifications proposed so far.

Clinical Classification

It is the oldest, user friendly classification which is still widely used. It divides salmonellae into two groups:

1. **Typhoidal *Salmonella*:** It includes serotypes *S.* Typhi and *S.* Paratyphi. They are restricted to human hosts, in whom they cause enteric fever (typhoid/paratyphoid fever).
2. **Non-typhoidal *Salmonella* or NTS:** The remaining serotypes can colonize the intestine of a broad range of animals, including mammals, reptiles, birds and insects. They also infect humans causing food-borne gastroenteritis and septicemia.

Antigenic Classification (Kauffmann–White Scheme)

The classification within the genus is based on the presence of different somatic (O) and flagellar (H) antigens which can be detected by agglutination with the respective antisera (Table 30.1).

- **Serogroups:** Based on O antigen, salmonellae are initially classified into serogroups.
  - Earlier, serogroups were named as letters, e.g. A, B, C and so on.
  - However, as the numbers increased, the serogroups are re-designated as numbers, e.g. 1, 2, 3 and so on.
  - Currently there are up to 67 serogroups, each containing group-specific O antigen, for example:
    - Serogroup-2 (formerly, serogroup A)—contains group specific O antigen type 2.
    - Serogroup-4 (formerly, serogroup B)—contains group-specific O antigen type 4.

TABLE 30.1: Kauffmann–White antigenic classification for *Salmonella*

Serogroup		Serotype name	O Ag*	Vi Ag	H Ag*	
New	Old				Phase 1	Phase 2
2	A	*S.* Paratyphi A	1,2,12	–	a	[1,5]
4	B	*S.* Paratyphi B	1,4,[5],12	–	b	1,2
		S. Typhimurium	1,4,[5],12	–	i	1,2
		S. Agona	1,4,12	–	f,g,s	–
		S. Heidelberg	1,4,[5],12	–	r	1,2
7	C1	*S.* Paratyphi C	6,7	+	c	1,5
		S. Choleraesuis	6,7	–	c	1,5
		S. Thompson	6,7,14	–	k	1,5
8	C2-C3	*S.* Muenchen	6,8	–	d	1,2
		S. Newport	6,8,20	–	e,h	1,2
9	D1	*S.* Typhi	9,12	+	d	–
		S. Enteritidis	1,9,12	–	g,m	[1,7]
		S. Gallinarum	1,9,12	–	–	–
		S. Dublin	1,9,12	+	g,p	–
3,10	E1	*S.* Anatum	3,10, [15],[34]	–	e,h	1,6

Note: *Antigen in brackets are not always present, Ag-antigen. Only some representative serotypes are given in the table

- Serogroup-9 (formerly, serogroup D)—contains group specific O antigen type 9.

- **Serotypes:** Each serogroup is further differentiated into serotypes, based on the type of flagellar antigens present. Currently, there are more than 2500 serotypes of salmonellae.

Molecular Classification

Based on DNA hybridization studies, the genus *Salmonella* consists of two species—*Salmonella enterica* and *S. bongori*.

- Within the species *S. enterica*, there are six subspecies differentiated by biochemical variations; namely *enterica*, *salamae*, *arizonae*, *diarizonae*, *houtenae* and *indica*.
- Each subspecies is further differentiated into serotypes (based on O and H antigens as described in the Kauffmann-White scheme).
- Most of the pathogenic typhoidal and non-typhoidal *Salmonella* serotypes are placed under species *enterica* and subspecies *enterica*.

Nomenclature

Taxonomically, the correct nomenclature of the members of salmonellae is very much complicated, e.g ***Salmonella* species *enterica* subspecies *enterica* serotype Typhi**.

- However, for routine use a simplified format is followed where only the genus and serotype names are included, for example *Salmonella* serotype Typhi or in short, *S.* Typhi.

ANTIGENIC STRUCTURE

Salmonellae possess three important antigens on their cell wall, based on which they are classified. The antigens are:

- Somatic antigen (O)
- Flagellar antigen (H)
- Surface envelope antigen (Vi)—found in some species.

Note: Fimbrial antigens may be present in some strains. They are non specific, widespread among other members of Enterobacteriaceae and may cause confusion in identification.

The O and H antigens are described in Table 30.2.

TABLE 30.2: Difference between somatic (O) and flagellar (H) antigen

O antigen	H antigen
Somatic antigen It is a part of cell wall lipopolysaccharide (LPS)	**Flagellar antigen** ▪ Made up of proteins flagellin ▪ It confers motility to the bacteria
Heat stable, Alcohol stable	Heat labile, Alcohol labile
Formaldehyde labile	Formaldehyde stable
In Widal test, O antigen of S.Typhi is used	In Widal test, H antigens of S.Typhi, S.Paratyphi A and B are used
O Ag is less immunogenic	H Ag is more immunogenic
O antibody appears early, disappears early: indicates recent infection	H antibody appears late, disappears late: indicates convalescent stage
When O antigen reacts with O antibody forms compact, granular, chalky clumps ▪ Agglutination takes place slowly ▪ Optimum temperature for agglutination is 55°C	When H antigen reacts with H antibody forms large, loose, fluffy clumps. ▪ Agglutination takes place rapidly. ▪ Optimum temperature for agglutination is 37°C
Serogrouping of salmonellae is based on the O antigen	Serogroups are differentiated into serotypes based on H antigen.
O antigen is also called the Boivin antigen because it can be extracted from the bacterial cell by treatment with trichloracetic acid—this property was first shown by Boivin	▪ Flagellar antigens exist in two alternative phases—Phase I and II. ▪ Most of them are biphasic except S. Typhi which is monophasic.

Vi Antigen

Vi antigen is a surface polysaccharide envelope or capsular antigen covering the O antigen. The naming is due to the belief that Vi antigen is related to virulence.

- It is expressed in only few serotypes, such as *S.* Typhi, *S.* Paratyphi C, *S.* Dublin and some stains of *Citrobacter freundii* (the Ballerup-Bethesda group).
- When Vi antigen is present, it renders the bacilli inagglutinable with the O antiserum. However, the strain becomes agglutinable after boiling or heating at 100°C for 1 hour, which removes Vi antigen and exposes the O antigen. Vi antigen is also destroyed by 1 N HCl and 0.5 N NaOH, but not by alcohol or 0.2% formaldehyde.
- As Vi antigen is **poorly immunogenic** and antibody titers are low, it is not helpful in the diagnosis of cases. Hence, the Vi antigen is not employed in the Widal test.
- However, it is believed that the complete absence of the Vi antibody in a proven case of typhoid fever indicates poor prognosis.
- The Vi antibody usually disappears early in convalescence, but if persists, indicates the development of the carrier state.
- Phage typing of *S.* Typhi can be done by using Vi specific bacteriophages.
- Vi antigens can also be used for vaccination.

Antigenic Variations

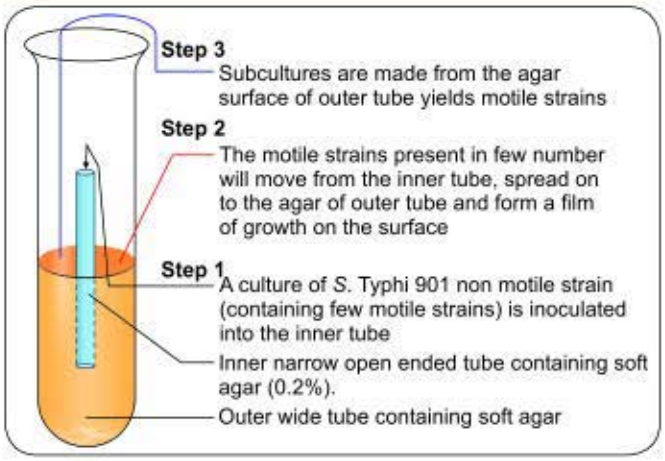
The antigens of salmonellae can undergo several types of phenotypic and genotypic variations.

Variation in O Antigen

- **S-R variation** (smooth to rough) is due to loss of the O antigen side chain from LPS, leading to exposure of core polysaccharide portion (or R antigen) of LPS.
  - Smooth colonies are produced by virulent strains carrying the O antigen.
  - Rough strains form large, rough, and irregular colonies and are avirulent due to loss of O antigen. Colonies are autoagglutinable in saline suspensions, and lack O serotype specificity, hence are not suitable for antisera testing.
  - S–R conversion takes place due to mutation, which frequently occurs by serial subculturing of the laboratory maintained strains.
  - S–R variation may be prevented by maintaining the cultures on Dorset's egg media in cold or by lyophilization.
- **Lysogenic conversion:** Infection with a bacteriophage to *Salmonella* may cause loss, gain or change of an O antigen. *S.* Anatum is converted into *S.* Newington by infection with one phage (gaining O15 antigen) and the latter into *S.* Minneapolis by another phage infection (gaining O34 antigen).

Variation in H Antigen

- **OH-O variation:** It is associated with the loss of flagella which can be induced by:
  - **Phenol agar:** Growing the cultures on agar containing phenol (1:800) causes inhibition of flagella temporarily which can be regained by subculturing on the media without phenol.
  - **By mutation:** This is seen in non-motile mutant of *S.* Typhi 901-O strain, employed in the Widal test. Here also, the loss of flagella is not total. The flagellated cells which are found in small numbers in such cultures can be revived by subculturing the culture in ***Craigie's tube*** (explained in Fig. 30.1). Alternatively, a U-tube containing soft agar may be used.
- **Phase variation:** The flagellar antigens exist in two phases. Each phase comprises of a distinct set of flagellar antigens.
  - Phase 1 antigens are serotype specific and designated as a, b, c, etc. Phase 2 antigens are nonspecific or group antigens. They are few in number and are designated as 1, 2, etc.
  - **Serotypes can be classified as:**
    - Diphasic: Most salmonellae possess antigens of both phases.
    - Monophasic: Some serotypes possess only phase 1 antigens, e.g. *S.* Typhi, *S.* Agona, *S.* Dublin, and *S.* Senftenberg.



Step 3
Subcultures are made from the agar surface of outer tube yields motile strains
Step 2
The motile strains present in few number will move from the inner tube, spread on to the agar of outer tube and form a film of growth on the surface
Step 1
A culture of S. Typhi 901 non motile strain (containing few motile strains) is inoculated into the inner tube
Inner narrow open ended tube containing soft agar (0.2%).
Outer wide tube containing soft agar

Fig. 30.1: Craigie's tube demonstrating the reviving of the motile strains from a mixture of motile/non motile strains of *S.* Typhi 901

    - Aphasic: *S.*Gallinarum does not have any flagellar antigens. Hence, it is non-motile.
  - For serotyping, it is essential to identify the antigens of both the phases.
  - Though flagellar genes for antigens of both phases are present in cultures of diphasic strains, generally only one phase antigen is expressed and gets agglutinated by its phase antisera.
  - Hence phase conversion has to be done to express the other phase antigens.
  - Phase conversion—a culture in phase 1 can be converted to phase 2 by passing it through a Craigie's tube containing specific phase 1 antiserum.

Variation in Vi Antigen (V–W Variation)

V forms of *S.* Typhi (strains carrying Vi antigens which mask the O antigens) are agglutinated by Vi antisera but not by O antisera. After serial subcultures, Vi antigen is lost completely and such strains **(W forms)** are agglutinable by O antisera but not by Vi antisera.

TYPHOIDAL SALMONELLA

Typhoidal salmonellae include *S.* Typhi and *S.* Paratyphi A, B and C which cause enteric fever. Pathogenesis is described below.

Pathogenesis

Salmonellae are transmitted by oral route, through contaminated food or water.

- **Infective dose of** *Salmonella* is higher than that of *Shigella*. Minimum 10^3–10^6 bacilli are needed to initiate the infection.

Contd...

Contd...

- **Risk factors** that promote transmission include the conditions that decrease:
  - Stomach acidity (<1 year age, antacid ingestion, or achlorhydria or prior *Helicobacter pylori* infection)
  - Intestinal integrity (inflammatory bowel disease, prior GIT surgery or suppression of the intestinal flora by antibiotics)
- **Entry through epithelial cells (M cells)** lining the intestinal mucosa-Salmonellae can trigger the formation of membrane ruffles on the cell membrane of M cells. These ruffles reach out and enclose the adherent bacteria within the large vesicles. This process of uptake is called **bacteria-mediated endocytosis (BME)**.
- **Mechanism of BME:** Salmonellae possess specialized type III secretion system which helps in direct delivery of bacterial proteins into cytoplasm of epithelial cells, leads to alterations in the actin cytoskeleton which is required for bacterial uptake. Following entry, the bacilli remain inside vacuoles in the cytoplasm.
- **Entry into macrophages:** Salmonellae containing vacuoles cross the epithelial layer to reach submucosa, where they are phagocytosed by the macrophages.
- **Survival inside the macrophages:** This occurs by—
  - *S.* Typhi induces certain alterations on its surface so that the bacilli are no longer susceptible to the lysosomal enzymes of macrophages. This is mediated by organism's regulatory systems such as **PhoP/PhoQ** system which triggers the expression of outer-membrane proteins and mediates modifications in LPS.
  - In addition, salmonellae encode a second type III secretion system that directly delivers bacterial proteins into the macrophage cytoplasm.
- **Primary bacteremia:** Salmonellae contained inside the macrophages spread via the lymphatics to enter the blood stream (transient primary bacteremia).
- **Spread:** Then, the bacilli disseminate throughout the reticuloendothelial tissues (liver, spleen, lymph nodes and bone marrow) and other organs, such as gallbladder, kidneys and lungs where further multiplication takes place.
- **Secondary bacteremia** occurs from the seeded organs, which leads to the onset of clinical disease.

Clinical Manifestations of Enteric Fever

Incubation period is about 10–14 days. Enteric fever is a misnomer as the manifestations are more extraintestinal than intestinal. Various manifestations are as follows.

- **Fever (step ladder pattern type of remittent fever):** Fever rises gradually to a higher level with every spike; then falls down. The temperature variation is more than 2°C, but does not touch normal.
- **Other symptoms:** Headache, chills, cough, sweating, myalgia and arthralgia
- **Rashes** (called **rose spots):** Faint, salmon-colored, blanching, maculopapular rash on the trunk and chest seen in 30% of patients at the end of the first week.
- **Early intestinal manifestations** such as abdominal pain, nausea, vomiting and anorexia.
- **Important signs** include hepatosplenomegaly, epistaxis and relative bradycardia.
- **Complications:** Gastrointestinal bleeding and intestinal perforation can occur mostly in the third and fourth weeks of illness.
- **Neurologic manifestations** occur rarely which include meningitis, cerebellar ataxia and neuropsychiatric symptoms (described as "muttering delirium" or "coma vigil") such as paranoid psychosis, hysteria, delirium and aggressive behavior.

Epidemiology

- **Host:** Humans are the only natural hosts for typhoidal salmonellae.
- **Mode of transmission:** It is by ingestion of contaminated water and food. Rarely homosexual and laboratory acquired transmissions have been reported.
- **Prevalence:** Worldwide, an estimated 22 million cases of typhoid fever (with 2 lakh deaths); and additional 6 million cases of paratyphoid fever occur annually.
- **Incidence** is:
  - Highest (>100 cases per 100,000 population per year) in south central and southeast Asia
  - Medium (10–100 cases per 100,000) in the rest of Asia, Africa, Latin America
  - Low (<10 cases per 100,000) in other parts of the world
- **Locality and age:** Enteric fever is—
  - More common in urban than rural areas
  - More common among young children and adolescents than in adults.
- **Factors** that favor transmission include—
  - Poor sanitation and improper cleaning of drinking water
  - Contaminated water, food and drinks
  - Lack of hand washing and toilet access, and evidence of prior *Helicobacter pylori* infection.
- **Typhi vs Paratyphi:** *S.* Typhi infection is more common than *S.* Paratyphi A (ratio is 4:1). However, *S.* Paratyphi A appears to be increasing, especially in India; may be due to increased vaccination for *S.* Typhi.
- **Carriage:** Up to 10% of untreated patients become carriers and excrete *S.* Typhi in feces or urine.
  - **Carriers are of two types:**
    - Fecal carriers: Typhoid bacilli multiply in the gall bladder and are excreted in feces. Fecal carriers are more common.

- Urinary carriers: Multiplication takes place in kidneys and bacilli are excreted in urine. Urinary carries are rare.

- **Duration of shedding:** Carriers continue to shed the bacilli in feces and urine for—
  - Convalescent carriers 3 weeks to 3 months (after clinical cure)
  - Temporary carriers 3 months to 1 year
  - Chronic carriers for more than 1 year.
- **Chronic carriers** occur in about 1–4% of infected people. Chronic carriage is more common in—
  - Women, infants and old age
  - Biliary tract abnormalities which leads to increased fecal excretion
  - Abnormalities of urinary tract and associated *Schistosoma haematobium* infection of bladder—leads to increased urinary excretion.
- **Food handlers or cooks** who become chronic carriers are particularly dangerous, can excrete the bacilli for many years. The best known example of such typhoid carrier was Mary Mallon **('Typhoid Mary'),** a New York cook who gave rise to more than 1300 cases during her lifetime causing several outbreaks.

- **Reference centers** for *Salmonella* in India—
  - National centre for *Salmonella* phage typing—at Lady Hardinge medical college, New Delhi.
  - National *Salmonella* Reference Centre—at Central Research Institute, Kasauli.
  - National *Salmonella* Reference Centre for animal origin—at Izatnagar.

LABORATORY DIAGNOSIS — Enteric fever

- **Culture isolation**
  - Blood and bone marrow culture (in first week of illness) in blood culture bottle (BHI broth, automated BACTEC)
  - Stool culture (in 3–4 weeks of illness):
    - Enrichment broth such as Selenite F broth, tetrathionate broth and gram-negative broth
    - Low selective media, e.g. MacConkey agar (translucent NLF colonies)
    - Highly selective medium: DCA, XLD agar, SS agar and Wilson Blair's bismuth sulphite medium (jet black colonies)
  - Urine culture (in 3–4 weeks of illness)—done on MacConkey agar
- **Culture smear and motility:** Motile, gram-negative bacilli
- **Biochemical identification**
  - Catalase positive and oxidase negative
  - Nitrate is reduced to nitrite
  - ICUT: Indole(–), Citrate(+/–), Urease(–)
    TSI:K/A, gas(+) except in *S.* Typhi, H_2S (*S.* Typhi- tiny, *S.* Paratyphi A-absent, *S.* Paratyphi B-abundant)

Contd...

Contd...

LABORATORY DIAGNOSIS — Enteric fever

- **Slide agglutination test:** To confirm the serotype
- **Serum antibody detection (Widal test):** 2–3 weeks of illness
  Antibodies are detected against TO, TH, AH, BH antigens
  - In *S.* Typhi infection: ↑TO and TH antibodies
  - In *S.* Paratyphi A infection: ↑TO and AH antibodies
  - In *S.* Paratyphi B infection: ↑TO and BH antibodies

  Result and interpretation
  - O antibodies: Appear early, disappear early, and produce granular chalky clumps when react with O Ag
  - H antibodies: Appear late, disappear late and produce cottony woolly clumps when react with H Ag
- **Antigen detection (serum and urine):** By ELISA, CIEP
- **Molecular methods:** PCR detecting *flagellin* gene, *iroB* and *fliC* gene
- **Nonspecific findings**—e.g. neutropenia
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Type of specimen to be collected depends on the duration of illness (Table 30.3). Blood, stool and urine are collected for culture and serum for serlogy.

Culture and Identification

Blood Culture

- **Blood culture** is the ideal method for diagnosis in the first week of fever, which becomes positive in about 90% of cases. There after the positivity declines to 75% in the second week and 60 % in the third week and 25% till the fever subsides.
- **Clot culture:** Blood is centrifuged, and then the serum is separated and used for Widal test and the clot is used for culture. Clot culture has shown a higher isolation rate than blood culture.

TABLE 30.3: Various tests used for diagnosis of enteric fever depending upon duration of illness

Duration of illness	Specimen used and test(s) done
First week	Culture of: ▪ Blood ▪ Bone marrow aspirate ▪ Duodenal aspirate
Second week and Third week	Serum: ▪ For antibody detection by Widal test ▪ For antigen detection Stool and urine culture
Fourth week	Stool and urine culture
Carriers	Stool and urine culture Serum for detection of antibodies to Vi antigen Sewage culture—indirect way

Figs 30.2A to C: Blood culture bottles. **A.** Monophasic medium (BHI broth); **B.** Biphasic medium (Castaneda's), containing BHI broth and BHI agar; **C.** BACTEC bottle

- **Culture medium:** There are two types of media used in blood culture bottles:
  1. Monophasic medium—contains 50–100 mL of brain heart infusion (BHI) broth (Fig. 30.2A)
  2. Castaneda's biphasic medium—consists of BHI agar slope and BHI broth (50–100 mL). (Fig. 30.2B)
- **Procedure:** 10-20 mL of fresh blood is directly injected into the blood culture bottle, containing 50-100mL of broth in 1:5 dilution. This is needed to overcome the effect of inhibitory substances present in the blood.
- **Sodium polyanethol sulfonate (SPS):** It is added to the medium as anticoagulant. It also counteracts the bactericidal action of blood.
- **Incubation:** Blood culture bottles are incubated at 37°C. Salmonellae are non fastidious, growth occurs within 24 hours. However, for isolation of other possible fastidious organisms in blood, e.g. for *Brucella*, incubation is carried out up to 1 week.
- **Repeat subcultures:**
  - From monophasic medium: Repeat subcultures are made onto blood agar and MacConkey agar periodically for 1 week. There is a risk of contamination due to opening of the cap of the bottle every time when subcultures are made.
  - Biphasic medium is preferred as the subcultures can be made just by tilting the bottles so that the broth runs over the agar slope. Bottle is incubated in upright position. If colonies appear over the agar slant, it is used for further identification.
- **Colony appearance**
  - Blood agar: Non hemolytic moist colonies
  - MacConkey agar: Colonies are round (1–3 mm size), translucent, pale and non-lactose fermenting.

Automated culture systems such BACTEC and Bact/Alert can be used alternate to blood culture bottles (Fig. 30.2C).

Stool and Urine Culture

It is useful for isolation of *Salmonella* in the third and fourth weeks of illness. They remain positive even after antibiotic treatment. Stool and urine culture are also done for detection of carriers.

Urine culture seldom becomes positive as salmonellae are shed in urine infrequently. Urine is centrifuged and the deposit is inoculated onto MacConkey agar.

Stool culture is done similar to that is followed for *Shigella* (Described in Chapter 29). Appropriate media should be used to inhibit the commensals in the stool.

- **Enrichment broth** such as Selenite F broth, tetrathionate broth and gram-negative broth are used.
- **Selective media** such as:
  - **Low selective media** such as MacConkey agar
  - **Highly selective media:** Growth of *S.* Typhi occurs as follows:
    - **DCA** (deoxycholate citrate agar): Produces non-lactose fermenting pale colonies with black center.
    - **XLD agar** (xylose lysine deoxycholate): Produces red colonies with black center (Fig. 30.3).
    - **SS agar** (*shigella Salmonella* agar): Colonies are colorless with black centers.
    - **Hektoen enteric agar:** Colonies are typically blue-green with black centers.
    - **Wilson Blair's** brilliant green Bismuth sulfite medium is particularly useful for the isolation of *S.* Typhi from heavily contaminated specimens.

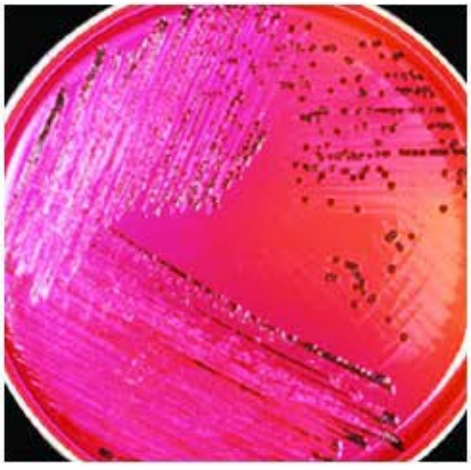


Fig. 30.3: Colonies of *S.* Typhi on XLD agar (Xylose lysine deoxycholate) showing red colonies with black center

S. Typhi produces characteristic **jet black** colored colonies with a **metallic sheen** due to production of H_2S. *S.* Paratyphi A and others that do not form H_2S produce green colored colonies.

Other Specimens

- **Bone marrow** culture is employed during the first week of illness (55–90% sensitive) when blood culture is negative, especially when patient is on antibiotics.
- **Duodenal aspirate** culture is recommended during first week of illness if both blood and bone marrow cultures turn negative.
- **Combination** of blood, bone marrow, and intestinal secretions culture is the best method in the first week, which shows a sensitivity of more than 90%.
- **Other materials** include rose spots, pus from suppurative lesions, CSF, sputum and autopsy specimens such as gallbladder, liver and spleen.

Culture Smear and Motility Testing

Gram-stain of colonies reveals gram-negative (2–4 × 0.6 µm size), non-sporing and non-capsulated bacilli. They are motile with peritrichous flagella except for *S.* Gallinarum and *S.* Pullorum. However, non-motile variants (OH → O) may be occasionally found within the serotypes.

Biochemical Identification

Serotypes of salmonellae show the following biochemical properties (see below and refer Table 29.3 of chapter 29).

Biochemical Identification of Salmonellae

- Catalase positive and oxidase negative

ICUT test:

- Indole test—negative
- Citrate test—positive (except for *S.* Typhi and *S.* Paratyphi A, which are citrate negative)
- Urease test—negative
- TSI (triple sugar iron test) shows:
  - Alkaline/acid
  - Gas present (except for *S.* Typhi, which is anaerogenic),
  - Abundant H_2S present except for
    - *S.* Paratyphi A and *S.* Choleraesuis: H_2S not produced
    - *S.* Typhi: Speck of H_2S present at the junction of slant and butt
- MR positive and VP negative
- Sugar fermentation test: Gluocse, mannitol, arabinose, maltose, dulcitol and sorbitol are fermented.
- **Decarboxylation test**
  - *S.* Typhi—only lysine is decarboxylated
  - *S.* Paratyph*i* A—only ornithine is decarboxylated
  - *S.* Paratyphi B—positive for all, i.e. lysine, arginine and ornithine.

Slide Agglutination Test

Identification of *Salmonella* at genus level can be confirmed by slide agglutination using polyvalent O antisera. Then, the serotypes can be identified by using type specific O antisera.

- *S.* Typhi: Agglutinates with O9 antisera
- *S.* Paratyphi A: Agglutinates with O2 antisera
- *S.* Paratyphi B: Agglutinates with O4 antisera

Flagellar antigens can also be determined by using type-specific H antisera.

Masking effect of Vi antigen: Sometimes, fresh isolates of *S.* Typhi are inagglutinable with O antisera due to presence of Vi antigen. Such strains should be either (1) tested with Vi antisera or (2) boiled for 60 minutes at 100°C to remove Vi antigen followed by testing with O antisera.

Antimicrobial Susceptibility Testing

It is done on Mueller–Hinton agar by disk diffusion method.

Demonstration of Serum Antibodies

Widal Test

Widal test is one of the oldest and most widely used serological tests for diagnosis of enteric fever. It was discovered by Fernand Widal in 1896.

- **Principle:** It is an agglutination test where H and O antibodies against *S.* Typhi and *S.* Paratyphi A and B are detected and measured in the patient's sera by using O and H antigens.
- **Antigens used:** Four antigens are used.
  - O antigens of *S.* Typhi (TO)
  - H antigens of *S.* Typhi (TH)
  - H antigens of *S.* Paratyphi A (AH)
  - H antigens of *S.* Paratyphi B (BH)

  (The paratyphoid O antigens cross-react with the typhoid O antigen due to their sharing of factor 12, hence they are not used in the test.)
- **Preparation of antigens:** Commercial Widal kits using stained antigens are available which are widely used now a days. In house antigen preparation is seldom followed.
  - The preparartion of antigen relies on the principle that—O antigen is heat-stable, alcohol-stable but formaldehyde-labile. H antigen is heat-labile, alcohol-labile but stable to formaldehyde.
  - **Strains used:** *S.* Typhi 901 'O' and 'H' strains and laboratory maintained strains for *S.* Paratyphi A and B.
  - **O antigen preparation:** The *S.* Typhi 901 O strain is cultured on 1:800 phenol agar (to inhibit H antigen) and the growth is scraped off in saline → mixed with 20 times its volume of absolute alcohol → heated at 40–50°C for 30 minutes → centrifuged → deposit is

re-suspended in saline → chloroform is added as a preservative.
- **H antigen preparation:** By adding 0.1% formalin to a 24 hour broth culture or saline suspension of an agar culture.

- **Procedure of Widal test**
  - Patient's serum is serially diluted in normal saline in test tubes from 1 in 10 to 1 in 640 dilutions. Four such sets are made.
  - To each set of diluted sera, respective four antigen suspensions (TO, TH, AH, BH) are added.
  - Control tubes containing the antigens and normal saline should be kept to check for autoagglutination.
  - Test tubes are incubated in water bath at 37°C overnight. Some authors recommend initial incubation at 50–55°C for 2 hours, followed by overnight incubation at room temperature.
- **Results**
  - O agglutination appears as compact granular chalky clumps (disk-like pattern), with clear supernatant fluid.
  - H agglutination appears as large loose fluffy cotton-woolly clumps, with clear supernatant fluid.
  - If agglutination does not occur, *button* formation occurs due to deposition of antigens and the supernatant fluid remains hazy.
  - *Titer:* The highest dilution of sera, at which agglutination occurs, is taken as the antibody titer.
- **Interpretation (Table 30.4)**
  - **Significant titer:** Any titer is not significant. In endemic countries like India, due to prior exposure, people will always have some base line antibodies. Higher titers are only significant. The cut-off varies from place to place depending on endemicity of the disease.
    - Significant titer in most of the places in India is taken as:
      - H agglutinin titer more than 200 and
      - O agglutinin titer more than 100

TABLE 30.4: Interpretation of Widal test

Widal test result	Suggestive of
Rise of TO and TH antibody	Enteric fever due to *S.* Typhi
Rise of TO and AH antibody	Enteric fever due to *S.* Paratyphi A
Rise of TO and BH antibody	Enteric fever due to *S.* Paratyphi B
Rise of only TO antibody	Recent infection: Due to any serotype-*S.* Typhi or *S.* Paratyphi A or B
Rise of only TH antibody	? Convalescent stage/ Anamnestic response
Rise of all TH, AH, BH antibodies	Post TAB vaccination

    - Low titers should be ignored and considered as baseline titers in endemic areas.
  - **False-positive:** Widal test may occur due to:
    - ***Anamnestic response:*** It refers to a transient rise of titer due to unrelated infections (malaria, dengue) in persons who have had prior enteric fever.
    - If bacterial antigen suspensions are not free from fimbriae
    - Persons with inapparent infection or
    - Persons with prior immunization (with TAB vaccine)
  - **Fourfold rise** in antibody titer demonstrated by testing paired sera at 1 week interval is more meaningful than a single high titer. Rise in titers in anamnestic responses is transient that usually falls after 1 week whereas, in true infection, the titer increases by fourfold after 1 week.
  - **False-negative:** Widal test may occur in:
    - Early stage (1st week of illness)
    - Late stage (after fourth week)
    - Carriers
    - Patients on antibiotics
    - Due to prozone phenomena (antibody excess)—This can be obviated by serial dilution of sera.
  - O agglutinins appear early and disappear early and indicate recent infection. H agglutinins appear late and disappear late.
  - O antibodies are serotype non-specific. They are raised in all infections, i.e. *S.* Typhi, *S.* Paratyphi A and B
  - H antibodies are specific. TH, AH and BH antibodies are raised *in S.* Typhi, *S.* Paratyphi A and B infections respectively.

Other Antibody Detection Tests

Various commercial methods available are:
- **Typhidot test:** OMP (outer membrane protein) antigen is used, detects both IgM and IgG antibodies
- **IDLTubex test:** O9 antigen is used, detects only IgM antibodies against *S.*Typhi.
- **IgM dip stick test** and **ELISA** detects anti-LPS IgM antibodies
- **Dot blot assay:** Flagellar antigen is used, detects only IgG antibodies.

Demonstration of Serum Antigens

Antigens of typhoidal salmonellae are consistently present in the blood in the early course of the disease, and also in the urine of patients during the late phase. Several methods are available for antigen detection:
- ELISA
- Coagglutination test and CIEP were used earlier, now not in use.

Molecular Methods

Several polymerase chain reaction (PCR) based methods (e.g. nested PCR) are available to detect and differentiate typhoidal salmonellae by targeting various genes, such as *flagellin* gene, *Iro B* and *FliC* gene.

Other Nonspecific Methods

- WBC count: Neutropenia is noticed in 15–25% of cases. Leukocytosis is more common among children, during early phase and in cases complicated by intestinal perforation or secondary infection.
- Liver function tests moderately elevated
- Muscle enzyme levels moderately elevated

Antimicrobial Susceptibility Testing

It is done on Mueller Hinton agar by disc diffusion method.

Detection of Carriers

- **Culture:** By stool and bile culture (detects fecal carriers) and urine culture (detects urinary carriers).
- **Detection of Vi antibodies:** It is done by tube agglutination test by using *S.* Typhi suspension carrying Vi antigen (Bhatnagar strains). Even a titer of 1:10 is also considered as significant. Though Vi antibody detection is useful, confirmation should always be made by culture.
- **Isolation of salmonellae from sewage:** It is carried out to trace the carriers in the communities. It can be done by:
  - Sewer-swab technique: Gauze pads left in sewers are cultured on highly selective media, such as Wilson and Blair media.
  - Filtration: Sewage can be filtered through millipore membranes and the membranes are cultured on highly selective media.

Typing of Salmonellae (Typhoidal and Non-typhoidal)

For adequate surveillance and determining the source of food-borne infections and outbreaks in hospitals (caused by non typhoidal salmonellae), several typing methods are used such as:

- **Phenotypic methods:** In general, phenotypic methods have low discriminatory power which limits their use as epidemiological tool.
  - **Phage typing** is done for *S.* Typhi, by using specific bacteriophage called Vi phage II which enters into the cell by using Vi antigen as receptor.
    - In India, the national *Salmonella* phage typing center is located at Lady Hardinge Medical College, New Delhi.
    - The phage types most widespread and abundant throughout the world are E1 and A, followed by B2, C1, D1, and F1.
  - **Bacteriocin typing:** It is based on the production of bacteriocin by the test strain that lyses specific sets of indicator strains.
  - **Biotyping:** It is based on biochemical properties of the strains, biotypes can be characterized. It is widely used for *S.*Typhimurium.
  - **Antibiogram typing:** It is based on antimicrobial resistance pattern.
- **Genotypic methods:** They have good discriminating ability. Widely used methods are as follows:
  - Plasmid typing: It is based on the numbers and molecular weight of plasmids which found in many *Salmonella* species
  - Chromosomal based—
    - Insertion sequence (IS) 200 typing: It has been shown to be more useful for certain serotypes (e.g. *S.* Infantis and *S.* Heidelberg)
    - Pulse field gel electrophoresis (PFGE)
    - Ribotyping
    - PCR-based methods, such as random amplified polymorphic DNA typing (RAPD) and PCR-RFLP (Restriction fragment length polymorphism).

TREATMENT **Enteric Fever**

Treatment of enteric fever (Table 30.5) depends on the susceptibility of the strains.

The currently recommended drugs are as follows:

- Fluoroquinolones, e.g. ciprofloxacin
- Third generation cephalosporins, e.g. ceftriaxone
- Azithromycin

Drugs that were used in the past were:

- Chloramphenicol
- Amoxicillin
- Cotrimoxazole

Drug Resistance in Typhoidal Salmonellae

- **Multidrug-resistant (MDR) *S.* Typhi:** It is defined as resistant to chloramphenicol, ampicillin and cotrimoxazole-antibiotics used to treat enteric fever long back. MDR strains emerged in 1989 in China and Southeast Asia including India and since then they have been disseminated widely.
- **NAR strains (Nalidixic acid resistant):** Due to the increased use of fluoroquinolones to treat MDR strains in 1990s, strains with reduced susceptibility to ciprofloxacin have emerged in India, other regions of southern Asia and sub-Saharan Africa (most recently).
- **Resistance to ceftriaxone:** It has been reported recently. Both extended spectrum β-lactamases (ESBLs) and AmpC β-lactamase producing *S.* Typhi have been detected.
- **Old is gold:** Interestingly, it is noticed that many strains reverted susceptible to the olden days drugs (amoxicillin, chloramphenicol, cotrimoxazole) as they were not in use for long time.

TABLE 30.5: Treatment of enteric fever

	Drug of choice	Alternate drug
Empirical treatment	This is the treatment given before antimicrobial susceptibility report is available.	
	Ceftriaxone[a]	Azithromycin[b]
Fully susceptible	Susceptible to all the drugs given for enteric fever.	
	Ciprofloxacin[c]	Amoxicillin Chloramphenicol Cotrimoxazole
MDR strains (Multidrug-resistant)	Defined as resistant to chloramphenicol, ampicillin and cotrimoxazole-antibiotics used to treat enteric fever long back	
	Ciprofloxacin	Ceftriaxone Azithromycin
NAR strains (Nalidixic acid resistant)	Defined as strains resistant to nalidixic acid with reduced susceptibility to ciprofloxacin	
	Ceftriaxone	Azithromycin, Ciprofloxacin[d] (higher dose and longer course)
Carriers	Ampicillin or Amoxicillin plus probenecid for 6 weeks	Cotrimoxazole or Ciprofloxacin

[a] 1–2 g/day (IV) for 7–14 days
[b] 1g/day oral for 5 days
[c] 500 mg twice a day oral for 5–7 days
[d] 750 mg twice a day per oral for 10–14 days

Prophylaxis

Theoretically, it is possible to control or eliminate enteric fever since the agents survive only in the human hosts and are spread by contaminated food and water. Many developed countries have proven this. However, in developing countries, this goal is currently unrealistic due to lack of adequate sewage disposal and water treatment. There are three lines of prophylactic measures.

Control of Reservoir

Control of Cases

- By early diagnosis and prompt effective treatment
- Disinfection of stool or urine soiled clothes with 5% cresol, 2% chlorine or by steam sterilizer
- Follow up examination of stool and urine culture to detect carriers (twice at 3–4 months and at 12 months).

Control of Carriers

- Early detection of carriers by stool/urine culture or by detection of Vi antibodies
- Effective treatment of carriers by:
  - Ampicillin or amoxicillin (4–6 g/day) plus probenecid (2 g/day) for 6 weeks. These drugs get concentrated in bile and may eliminate 70% of carriers.
  - Surgery: Cholecystectomy plus ampicillin is regarded as the most effective approach for carrier state elimination (80% cure rate).

Sanitation measures

Sanitation measures include the following:

- Protection and purification of drinking water supplies
- Hand washing and improvement of basic sanitation
- Promotion of food hygiene
- Health education

Vaccine

Immunization provides protection for a short time period. It is indicated in following situations:

- Travelers going to endemic areas
- People attending to *melas* and *yatras*
- Household contacts
- People at increased risk (school children)
- People living in endemic area (optional)

There are three types of vaccines available (see below).

Vaccines for Typhoid Fever

- **Parenteral TAB vaccine** (heat-killed whole cell *S.* Typhi/ *S.* Paratyphi A and B): It is no longer in use because of significant side effects.
- **Parenteral Vi polysaccharide vaccine:** It is composed of purified Vi capsular polysaccharide antigen derived from *S.* Typhi strain Ty2.
  - Dosage: Single dose containing 25 µg of Vi antigen is given IM or subcutaneously.
  - Vaccine confers protection for 2 years.
  - Vi antigen elicits T independent IgG antibody response that is not boosted by additional dose of vaccine.
  - Age- It is given only after 2 years of age.
- **Typhoral (oral live attenuated S. Typhi Ty2 1a vaccine):**
  - Typhoral is a stable live attenuated mutant of *S.* Typhi strain Ty2 1a, which lacks the enzyme UDP-galactose-4-epimerase (Gal E mutant).
  - On ingestion, it multiplies for some time, initiates the immune response but self destructs (dies of its own after 4–5 cell divisions, due to lack of Gal E enzyme) and therefore cannot induce any pathogenesis.
  - It is indicated only after 6 years of age.
  - The vaccine is available in lyophilized form as **enteric coated capsules**.
  - It is given orally before food, on alternate days- 1, 3, 5 and/ or 7 (total of three or four doses). No antibiotics should be given during this period.
  - **Protective immunity** starts after 7 days of the last dose and lasts for 4 years.
  - **Boosters** are recommended every 3 years for people residing in endemic areas and every year for travelers proceeding to endemic areas.

NON-TYPHOIDAL SALMONELLAE (NTS)

Non-typhoidal salmonellae include the pathogenic salmonellae other than *S.* Typhi and *S.* Paratyphi A, B and C. Majority of infections due to NTS are caused by *S.* Typhimurium and *S.* Enteritidis followed by *S.* Newport, *S.* Javiana, *S.* Heidelberg, *S.* Choleraesuis and *S.* Dublin.

Non-typhoidal Salmonellae vs Typhoidal Salmonellae

Non-typhoidal salmonellae (NTS) differ from typhoidal salmonellae in many respects:

- **Zoonotic:** NTS can be acquired from multiple animal reservoirs (whereas the typhoidal salmonellae are strictly human pathogens).
- **Transmission** of NTS is most commonly associated with animal food products, especially eggs, poultry, undercooked ground meat and dairy products. (typhoidal salmonellae are mainly water-borne).
- **Resistance:** Compared to other enteric gram-negative pathogens, salmonellae are relatively resistant to many environmental factors, such as drying, salting, smoking and freezing. This explains why they survive in diverse range of foods.
- **Seasonality:** Transmission of NTS is highest during the rainy season in tropical climates and during the warmer months in temperate climates, coinciding with the peak in food-borne outbreaks.
- **Prevalence:** NTS are widely prevalent in developed as well as developing countries (typhoidal salmonellae are mainly confined to developing countries).
- **Outbreaks** of NTS are common in hospitals (typhoidal salmonellae outbreaks are community based).
- **Pathogenesis** is similar to that of enteric fever except that in NTS gastroenteritis, there is massive neutrophil infiltration into intestinal mucosa (in contrast to enteric fever, where there is mononuclear cells infiltration).

Clinical Manifestations

- **Gastroenteritis:** Infection with NTS most often results in gastroenteritis - characterized by nausea, vomiting, watery diarrhea, fever and onset of abdominal cramps 6–48 hours after the ingestion of contaminated food. (gastroenteritis is uncommon in typhoidal salmonellae)
- **Bacteremia:** Up to 8% of patients with NTS gastroenteritis develop into bacteremia which leads to either endovascular infection or seedling to various organs leading to metastatic localized infection. Risk factors for bacteremia include—
  - NTS serotype: Most common being *S.* Choleraesuis (source-pig) and *S.* Dublin (source—cattle)
  - Age-Infants and elderly people are at higher risk
  - HIV and other conditions with low immunity
- **Endovascular infections**, such as endocarditis and arteritis, occur rarely in people with preexisting valvular heart disease.
- **Metastatic localized infections** such as:
  - Intra-abdominal infections, such as hepatic or splenic abscesses or cholecystitis
  - NTS meningitis (commonly in infants)
  - Pulmonary infections, such as lobar pneumonia and lung abscess.
  - UTI (pyelonephritis and cystitis) in people with underlying renal stones or urinary tract abnormality
  - Genital tract infections include ovarian, testicular abscesses, prostatitis and epididymitis.
  - *Salmonella* osteomyelitis: It is commonly associated with sickle cell disease
  - **Reactive arthritis** (Reiter's syndrome) seen in persons with HLA-B27 histocompatibility antigen.

TREATMENT **Non-typhoidal salmonellae**

In contrast to enteric fever where antibiotics are started as early as possible, in uncomplicated NTS gastroenteritis, the treatment is conservative with fluid replacement.

- Antibiotic use is associated with increased rates of carriers and relapse, hence it is limited only to invasive NTS infection or severe gastroenteritis having higher risks of developing invasive infection.
- Drugs given are similar to that of enteric fever.
  - Ciprofloxacin is given for preemptive treatment or severe gastroenteritis.
  - Ceftriaxone is indicated for bacteremia and invasive infections.

Drug Resistance

NTS are more drug resistant than typhoidal salmonellae.

- MDR strains of NTS are resistant to more than 5 drugs- ampicillin, chloramphenicol, streptomycin, sulfonamides and tetracyclines (abbreviated as **ACSSuT**).
- Increased use of ceftriaxone and ciprofloxacin to treat MDR strains leads to emergence of resistance to ceftriaxone (due to production of AmpC β-lactamases) and ciprofloxacin (due to point mutation in DNA gyrase genes).

EXPECTED QUESTIONS

I. Essay:

1. Meena, a young adult female was admitted to the hospital with intense headache, abdominal discomfort for the past 5 days. She had also developed fever which is of remittent type with gradual rise in a step ladder fashion. On examination, she was toxic with temperature of 101° F, tongue was coated and mild splenomegaly was present.
   a. What is the most probable etiological diagnosis?
   b. Describe the pathogenesis of this condition?
   c. Mention sample collection and laboratory diagnosis in detail?
   d. Add a note on treatment and vaccination available for this clinical condition?

II. Write short notes on:

1. Typhoid carriers
2. Drug resistance in salmonellae
3. Non-typhoidal salmonellae

III. Multiple Choice Questions (MCQs):

1. All of the following salmonellae are motile except:
a. *S.* Typhi b. *S.* Enteritidis
c. *S.* Gallinarum d. *S.* Chester

2. *S.* Typhi is the causative agent of typhoid fever. The infective does of *S.* Typhi:
a. One bacillus b. $10^3 - 10^6$ bacilli
c. $10^8 - 10^{10}$ bacilli d. 1–10 bacilli

3. In a patient with typhoid, diagnosis after 15 days of onset of fever is best done by:
a. Blood culture b. Stool culture
c. Urine culture d. Widal test

Answers

1. c **2.** b **3.** d

CHAPTER 31

Vibrio and Aeromonas

Chapter Preview

- Vibrio
  - Vibrio cholerae
    - Halophilic vibrios
- Aeromonas species

Earlier, family Vibrionaceae comprised of four genera—(1) *Vibrio*, (2) *Aeromonas*, (3) *Plesiomonas* and (4) *Photobacterium*. However, the taxonomy has been greatly changed.

- *Aeromonas* has now been given its own family status, the Aeromonadaceae.
- The taxonomy of *Plesiomonas* remains controversial; it is closely related to *Proteus* and recently has been placed into family Enterobacteriaceae (described in Chapter 29).
- *Photobacterium* is a plant pathogen.

VIBRIO

Vibrios are curved gram-negative bacilli that are actively motile by means of single polar flagellum.

- The organism was first described and named by Filippo Pacini in 1854. The name 'Vibrio' is derived from its characteristic vibratory motility.
- Robert Koch isolated the organism in 1886, and named it as Komma bacillus (due to its characteristic **curved** or **comma-shaped** appearance).
- They are fermentative, strongly aerobic, oxidase positive (except *V. metschnikovii*), non-sporing and non-capsulated (except *V. parahaemolyticus* and *V. vulnificus* which are capsulated).
- Growth is stimulated in presence of salt—a unique property exhibited by all vibrios. However, the optimum salt concentration required, varies among different vibrios.
- **Habitat:** Vibrios are ubiquitous, found worldwide. Being salt loving, the natural habitat of vibrio is the in marine environments (sea water and sea food), surface waters, river and sewage.
- Of the 35 *Vibrio* species recognized, only 12 have been associated with human infections.
- Among them, the most important is *V. cholerae* that causes a devastating acute diarrheal disease **'cholera'** and has been responsible for seven global pandemics and several epidemics over the past two centuries.

VIBRIO CHOLERAE

Classification

Based on Salt Requirement

Based on salt requirement, vibrios can be classified into:

- **Nonhalophilic vibrios:** They can grow without salt, but 1% salt is optimum for their growth. They cannot grow at higher salt concentrations. Examples include *V. cholerae* and *V. mimicus*.
- **Halophilic vibrios:** They cannot grow in the absence of salt. They can tolerate and grow at higher salt concentration of upto 7–10%. Examples include *V. parahaemolyticus*, *V. alginolyticus* and *V. vulnificus*.

Heiberg Classification (1934)

Heiberg classified vibrios into eight groups based on fermentation of three sugars—mannose, arabinose and sucrose. V. cholerae was placed in Group I.

Gardner and Venkatraman Classification

This classification of *V. cholerae* (1935) was based on serogrouping, biotyping, serotyping and phage typing. This classification was later on updated by several researchers. Such typing schemes are of great epidemiological importance in tracking the outbreaks by finding out the relatedness between the isolates in different clinical specimens (Fig. 31.1).

Serogrouping

Based on somatic O antigen, *V. cholerae* can be grouped into more than 200 serogroups or serovars (updated by the most widely used Sakazaki typing scheme).

- **O1 serogroup:** Among all serogroups, O1 was responsible for all pandemics and most of the epidemics

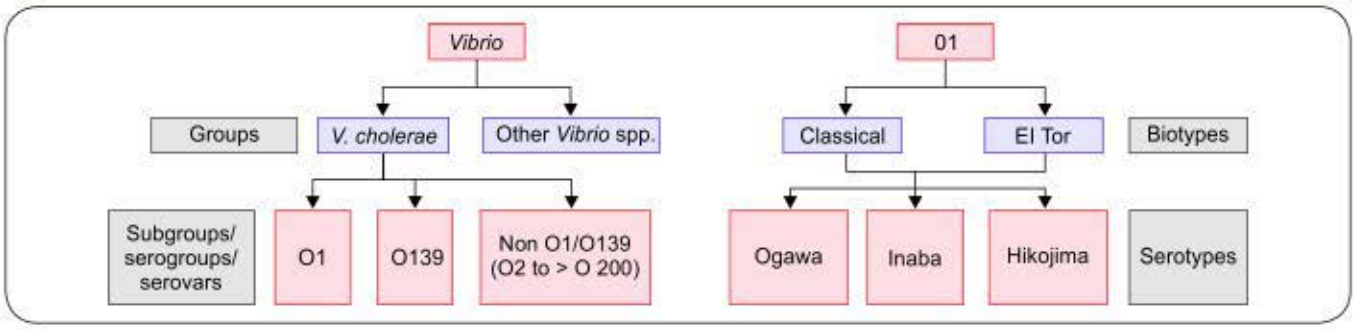

Fig. 31.1: Gardner and Venkatraman classification of *V. cholerae*

of cholera. Strains belonging to O1 serogroup are agglutinated by O1 antisera.

- **NAG vibrios:** Serogroups other than O1 were not agglutinated by O1 antiserum and were called non-agglutinable or NAG vibrios. They were thought to be non-pathogenic, hence also named as **non-cholera vibrios (NCV)**. Later on, it was observed that many other serogroups are pathogenic to man and are agglutinable with their respective antisera. Hence these terms such as NAG or NCV are no longer in use.
- **O139 serogroup:** It was identified in 1992 and since then it has caused several epidemics and outbreaks of cholera in the coastal regions of India and Bangladesh.
- **Non O1/O139 serogroups:** They have occasionally caused sporadic outbreaks of diarrhea and extraintestinal manifestations, but have never caused epidemic cholera so far.

Serotyping

O1 serogroup can further be divided into three serotypes—Inaba, Ogawa, and Hikojima; based on minor antigenic differences of O antigen (Table 31.1).

- Ogawa is the most common serotype isolated from clinical samples followed by Inaba.
- However, during epidemics, shifting between serotypes can take place, more common being Ogawa to Inaba shift which occurs due to mutations in *rfbT* gene.
- Hikojima represents an unstable transitional state; where both Inaba and Ogawa antigens are expressed.

Biotyping

Serogroup O1 has two biotypes—classical and El Tor; differentiated by various biochemical reactions and their susceptibility to polymyxin B and bacteriophages (Table 31.2).

TABLE 31.1: Serotypes of *V. cholerae* O1 and their distinct O antigen types

Serotype	O antigen types
Ogawa	A,B
Inaba	A,C
Hikojima	A,B,C

TABLE 31.2: Differences between classical and El Tor *V. cholerae*

Biotypes of *V. cholerae* O1	Classical biotype	El Tor biotype
β hemolysis on sheep blood agar	Negative	Positive
Chick erythrocyte agglutination	Negative	Positive
Polymyxin B (50 IU)	Susceptible	Resistant
Group IV phage susceptibility	Susceptible	Resistant
El Tor Phage V susceptibility	Resistant	Susceptible
VP (Voges Proskauer) test	Negative	Positive
CAMP test	Negative	Positive
Cholera toxin gene	CTX-1	CTX-2

Abbreviation: CAMP test, Christie Atkins Munch-Petersen test

- **Classical biotype:** It was responsible for the first six pandemics of cholera worldwide. It was highly virulent and had caused several deaths.
- **El Tor biotype** replaced the classical biotype by 1961 and caused the seventh pandemic of cholera. It was first identified by Gotschlich (1905) at a quarantine camp on the Sinai Peninsula in El-Tor, Egypt.
- **Currently,** almost all outbreaks or epidemics of cholera are due to biotype El Tor, although occasional classical isolates are still seen. However, some isolates do not fit into both the biotypes and are called as **El Tor variants**.

Variants of El Tor Biotype

Several variants of El Tor biotype have been described recently in Bangladesh and in few other places of Asia and Africa. They show properties overlapping with both El Tor and classical biotypes. Variants of El Tor biotype include the following types:

- **Matlab variants (El Tor hybrid):** These strains could not be biotyped because they have a mixture of both classical and El Tor properties, were described first in Bangladesh since 2002.
- **Mozambique variant** (2004–2005): It has a typical phenotypic properties and genome of El Tor, except that the cholera toxin and its gene (CTX) are of classical type.

Phage Typing

El Tor and classical biotypes can also be differentiated based on their susceptibility to different lytic bacteriophages.

- Basu and Mukherjee phage typing was the most widely used scheme to differentiate O1 biotypes.
- It was later updated by Chattopadhyay (1993), and then it has been expanded to include O139 strains (Chakrabarti, 2000).

Pathogenesis of Cholera

Pathogenesis of cholera is toxin-mediated. Both *V. cholerae* O1 and O139 are capable of producing cholera toxin, thus resulting in cholera.

- **Mode of transmission:** *V. cholerae* is transmitted by ingestion of contaminated water or food.
- **Infective dose:** Since *V. cholerae* is extremely acid-labile; a high infective dose of 10^8 bacilli is required to bypass the gastric barrier.
- **Factors promoting transmission:** These include all those conditions where gastric acidity is reduced, such as hypochlorhydria, use of antacids, etc.
- **Crossing of the protective layer of mucus:** In the small intestine, vibrios penetrate the mucous layer and reach near the epithelial cells, which may be achieved by:
  - Its highly active motility
  - Secreting mucinase and other proteolytic enzymes
  - Secreting hemagglutinin protease (cholera lectin): It cleaves the mucus and fibronectin. It also helps in releasing vibrios bound to intestinal mucosa, facilitating their spread to other parts of the intestine and also their fecal shedding.
- **Adhesion and colonization:** The next step in the pathogenesis is, its adhesion to the intestinal epithelium which is facilitated by a special type IV fimbria called **toxin coregulated pilus** (TCP). It is so named because the synthesis of TCP, cholera toxin and several other virulence factors are co-regulated by a single gene called *ToxR*.
- **Cholera toxin (CT):** Once established in the human small intestine, the organism produces a powerful enterotoxin called cholera toxin. It resembles heat-labile toxin (LT) of *E. coli* in its structure and function, but it is more potent than the latter.
- **Mechanism of action of cholera toxin:** The toxin molecule is about 85 kDa; consists of two peptide fragments—A and B (Fig. 31.2).
  - **Fragment B** is the binding fragment and is pentameric, contains **five subunits** each weighing 11.7 kDa each. It binds to GM1 ganglioside receptors present on the intestinal epithelium, following which A fragment is internalized and cleaved into A1 and A2 peptides.

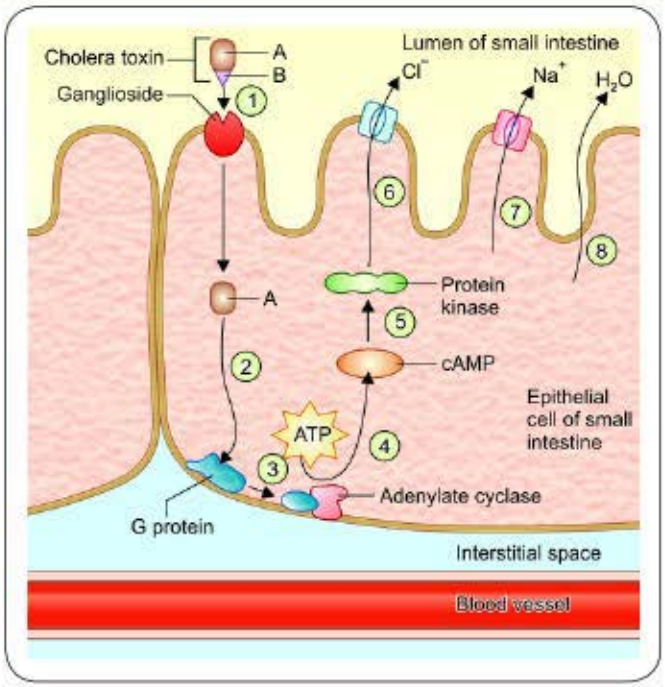

Fig. 31.2: Mechanism of action of cholera toxin

  - **Fragment A2** helps in tethering A and B subunits together.
  - **Fragment A1** is the active fragment (27 kDa), causes ADP ribosylation of G protein → upregulates the activity of adenylate cyclase → result is the intracellular accumulation of cyclic adenosine monophosphate (cAMP).
- **Increase in cyclic AMP leads to:**
  - In small intestine, cyclic AMP inhibits the absorptive sodium transport system in villus cells and activates the secretory chloride transport system in crypt cells, which lead to the accumulation of sodium chloride in the intestinal lumen.
  - Water moves passively into the bowel lumen to maintain osmolality which leads to the accumulation of isotonic fluid that results in watery diarrhea.
  - Loss of fluid and electrolytes leads to shock (due to profound dehydration) and acidosis (due to loss of bicarbonate).
- **Gene for cholera toxin** (CTX): It is a part of pathogenicity island of the organism, encoded by genome of a filamentous bacteriophage (CTXϕ) which is integrated as prophage into the bacterial chromosome. TCP present on the surface of *V. cholerae* is the receptor for this bacteriophage.
  - In this phage coded pathogenicity island, many other genes important for pathogenicity are clustered together such as genes encoding the biosynthesis of

TCP, accessory colonization factors, and regulator genes.
  - It is believed that the pathogenicity islands are acquired by horizontal gene transfer through bacteriophage which may account for the emergence of new toxigenic *V. cholerae* serogroups such as O139 (probably derived from an El Tor O1 strain).
- ***ToxR* gene:** It regulates the expression of CT, TCP and other virulence factors and is itself regulated by environmental factors, such as heat-shock response.
- **Chromosomes:** *V. cholerae* has two circular chromosomes, one large and one small.
  - Large chromosome bears the pathogenicity island, which is needed for its growth and intestinal survival.
  - Small chromosome bears the gene essential for regulatory and metabolic pathways needed for environmental survival.
- **Other virulence factors include:**
  - Zona occludens toxin: It disrupts the tight junctions between mucosal cells.
  - Accessory cholera enterotoxin: It is associated with phage packaging and secretion.
  - Vero cell toxin: It is analogous to the toxin produced by *Shigella dysenteriae* 1. Its role in the intestine is not clear; however, it is important for the survival of the bacilli in aquatic environment.
  - Accessory colonization factors: They help in adhesion and colonization.
  - Siderophore: It is required for iron acquisition.
  - Bacterial endotoxin (LPS): Unlike other gram-negative bacilli, the LPS of *V. cholerae* does not contribute to the pathogenesis of cholera. However, it is immunogenic, and is included as a component in killed vaccines.

Clinical Manifestations of Cholera

V. cholerae O1 or O139 infections produce a range of clinical manifestations such as:

1. Asymptomatic infection (75% of cases)
2. Mild diarrhea or cholera (20% of cases)
3. Sudden onset of explosive and life-threatening diarrhea (*cholera gravis*, in 5% of cases).

Incubation period varies from 24 to 48 hours. The usual manifestations include:

- **Watery diarrhea:** Cholera characteristically begins with the sudden onset of painless watery diarrhea that may quickly become voluminous.
- **Rice water stool:** The stool is typically non-bilious, slightly cloudy and watery with mucus flakes and a fishy, inoffensive odour. Being non-invasive, there is no associated blood or pus cells in stool. It often resembles the water in which rice has been washed.

TABLE 31.3: Complications of cholera

Loss of body weight by	Symptoms
<5%	Increased thirst
At 5–10%	▪ Postural hypotension ▪ Weakness ▪ Tachycardia ▪ Decreased skin turgor
At >10%	Renal failure (due to acute tubular necrosis) and fluid loss result in— ▪ Oliguria ▪ Weak or absent pulses ▪ Sunken eyes ▪ Sunken fontanelles in infants ▪ Wrinkled ("washerwoman") skin ▪ Somnolence and coma

- Vomiting may be present but fever is usually absent.
- Muscle cramps may occur due to electrolyte imbalance.
- **Complications** are directly proportional to the fluid loss, which results in loss of body weight (Table 31.3).

Epidemiology

History of Pandemics

Cholera can occur in many forms—sporadic, limited outbreaks, endemic, epidemic or pandemic.

- **Home land:** The **delta region** of the Ganges and Brahmaputra in West Bengal (India) and Bangladesh was known to be the homeland of cholera since ancient times.
- **Till early nineteenth century**, cholera was virtually confined to its home land, causing large epidemics periodically.
- **First six pandemics** occurred between 1817 and 1923. All were caused by the classical biotype of *V. cholerae* which had spread from Bengal to involve most of the world; resulted in several thousands of deaths.
- After the end of the 6th pandemic, **from 1923 to 1961** cholera was largely restricted to its home land.
- **Seventh pandemic:** It was started in 1961 and it differed from the first six pandemics in many ways.
  - It was the only pandemic that originated outside India, i.e. from Indonesia (Sulawesi, formerly Celebes Island) in 1961. India was affected in 1964 and the whole world was encircled by 1991.
  - It was the only pandemic to be caused by El Tor biotype which had largely replaced the classical biotype by that time.
  - El Tor produced a much milder cholera; however, El Tor infection was associated with more carrier rate than the classical. This is due to the fact that El Tor is

much hardier than the classical vibrios and capable of surviving in the environment much longer.
  - This accounts for rapid spread of El Tor, involving the entire globe including some parts, such as Central and South American countries, Australia and other affluent countries which were never affected before.
- **O139 (Bengal strain):** It was isolated first from Chennai in 1992. Since it was not agglutinated by any of the antisera available at that time (O1 to O138), it was designated as a new serogroup O139 or the **Bengal strain** as it spread rapidly along the coastal region of Bay of Bengal up to West Bengal, then to the adjacent areas of Bangladesh.
  - O139 appears to be a derivative of O1 El Tor, but differs from the latter in having a distinct LPS and being **capsulated**. As a result, it is invasive and can cause bacteremia and extraintestinal manifestations also.
  - There is no cross protection between O1 and O139.
  - O139 had caused large-scale outbreaks of clinical cholera and spread rapidly across almost 11 Asian countries and became a threat to cause the next pandemic.
  - However, by 1994 the fear had come down and once again the O1 El Tor became dominant and largely replaced O139.
  - Currently, O139 still causes a minority of cases in India and Bangladesh.

Current Situation

In the World

Cholera is a notifiable disease. However, it is often under reported, hence the true incidence is unknown. It is possible that more than 3 million cases of cholera occur yearly (of which only 2 lakh cholera cases are reported to WHO), resulting in more than 1 lakh deaths annually (of which <5000 are reported to WHO).

- Several outbreaks have been recently reported such as from Zimbabwe (2009) and from Haiti (2010).
- Majority of cases are due to O1 El Tor. However, occasional cases may occur due to O139 and classical biotype, especially in Bangladesh.

In India

The situation has greatly changed in India both geographically as well as in terms of number of cases and deaths.

- West Bengal is no longer the home land; almost all the states have been affected.
- Both morbidity (number of cases) and mortality (deaths) have greatly reduced. In 2011, about 2,341 cases were reported with 10 deaths, in contrast to more than 1,76,307 cases with 86,997 deaths in 1950.
- El Tor dominance continues, while O139 causes minority of cases.
- **NICED:** National reference Center for cholera in India is located at National Institute of Cholera and Enteric Diseases (NICED), Kolkata.

Epidemiological Determinants

- **Reservoir:** Humans are the only reservoir of infection. There is no known animal reservoir.
- **Source:** The source of the infection may be either asymptomatic cases or carriers.
- **Carriers:** They are apparently healthy people who shed the bacilli in feces. Carriers may be:
  - Incubatory carriers: They are less common, as cholera has a short incubation period of 1–2 days.
  - Convalescent carriers: They are the recovered patients who shed the bacilli for 2–3 weeks.
  - Contact or healthy carriers: They contract the infection from subclinical cases and inturn shed the bacilli for less than 10 days.
  - Chronic carriers: Minority of convalescent carriers become chronic carriers.

  In general, biotype El Tor has more carrier rate than classical. The case–carrier ratio is 1: 50 for the classical biotype and 1:90 for the El Tor biotype.
- **Cholera season:** Maximum transmission is associated with high temperatures, heavy rainfall and flooding, but cholera can occur throughout the year.
- **Other factors** that promote transmission include poor sanitation, poverty, overcrowding, population mobility (as occurs in pilgrimages, fairs, festivals and marriages).
- **Factors determining severity** of the disease include:
  - Lack of preexisting immunity
  - Persons with **'O' blood group** are at greater risk of severe disease if infected, while those with type AB blood group are at least risk. The reason is not clear.
  - Malnutrition
  - People with low immunity (e.g. HIV infected people)
- **Age:** During inter epidemic period, all the age groups are affected equally, however during epidemics it affects more number of children.
- **Habitat:** *V. cholerae* is a natural inhabitant of coastal sea salt water and brackish estuaries, where the organism can persist for long periods, particularly in association with small crustaceans, such as copepods, crabs or plankton.
- **Persistence** of *V. cholerae:*
  - During epidemics, it is maintained by carriers and subclinical cases.
  - In inter epidemic period, it is maintained in sea water, crustaceans and planktons.

- **Resistance**
  - *V. cholerae* is acid-labile but stable to alkali.
  - It is heat-labile (killed within 30 minutes by heating at 56°C or within few seconds by boiling), but stable to refrigeration and can remain in ice for 4–6 weeks.
  - Drying and sunshine can kill the bacilli in few hours.
  - It is susceptible to disinfectants, such as cresol and bleaching powder (6 mg/L).
  - In general, biotype El Tor is more resistant than classical.

LABORATORY DIAGNOSIS *Vibrio cholerae*

- **Specimens:** Watery stool or rectal swab (for carriers)
- **Transport media:** VR medium, Cary-Blair medium
- **Direct microscopy**
  - Gram-negative rods, short curved comma-shaped (fish in stream appearance)
  - Hanging drop-demonstrates darting motility
- **Culture**
  - Enrichment broth: APW, Monsur's taurocholate tellurite peptone water
  - Selective media: Bile salt agar, Monsur's GTTT agar, TCBS agar (yellow colonies)
  - MacConkey agar-produces translucent NLF colonies
- **Culture smear and motility testing**—reveals
  - Short curved gram-negative bacilli and
  - Darting motility
- **Biochemical identification**
  - Catalase and oxidase positive
  - ICUT: Indole (+), Citrate (+/–), Urease (–), TSI:A/A, gas (–), H_2S (–)
  - Cholera red reaction positive
  - String test positive
  - Salt tolerance test positive
  - Ferments glucose and sucrose
- **Biotyping:** To differentiate Classical and El Tor
- **Serogrouping:** To differentiate O1 and O139
- **Serotyping:** To differentiate Ogawa, Inaba and Hikojima serotypes of serogroup O1
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Specimens

- Freshly collected watery stool is the specimen of choice for acute cases. Ideally, it should be collected before starting the antibiotics.
- Rectal swab is the preferred specimen for convalescent patients or carriers.

Transport/Holding Media

Specimens should be transported immediately to the laboratory. If delay is expected, stool or rectal swabs may be inoculated in transport media, where the bacilli do not multiply but remain viable for several weeks. 1–3 mL of stool is mixed in 10–20 mL of various transport media such as—

- **Venkatraman-Ramakrishnan (VR) medium:** It is composed of crude sea salt (20 g) and peptone (5 g) in one litre of distilled water at pH 8.6–8.8.
- **Alkaline salt transport medium** is same as VR medium; in addition, it has boric acid, NaOH and KCl and has a pH of 9.2.
- **Cary-Blair medium:** This is a buffered solution of sodium chloride, sodium thioglycollate, disodium phosphate and calcium chloride, at a pH 8.4. It is also useful for *Salmonella* and *Shigella*.
- **Autoclaved sea water** can also be used when other transport media are not available.

Direct Microscopy

- **Gram-staining** of mucus flakes of feces reveals short curved **comma-shaped** gram-negative rods, arranged in parallel rows, which is described by Koch as **fish in stream** appearance (Fig. 31.3).
- **Motility testing by hanging drop method:** They are actively motile frequently changing their direction, described as **darting motility** (dart means a small, slender, pointed missile which shows sudden, rapid movement when thrown at a target). It is also described as shooting star or swarming gnats motility.
  - At times, it is difficult to differentiate darting motility of *V. cholerae* from active motility of other bacteria such as *Pseudomonas*. More so few other bacteria can also produce darting motility (e.g. *Campylobacter* and *Aeromonas*).
  - **Motility testing after adding H-antisera:** *V. cholerae* becomes non-motile when a drop of the watery stool specimen is added with flagellar (H) antiserum. This differentiates it from other actively motile organisms. It is a simple and reliable method which confirms the diagnosis.

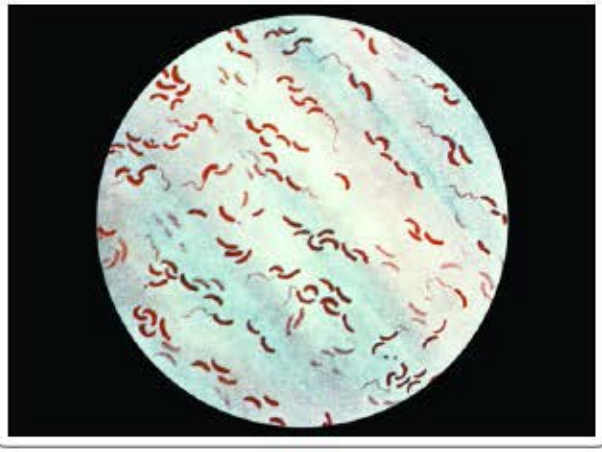

Fig. 31.3: *Vibrio cholerae* (Gram-stain): Curved comma-shaped gram-negative rods (fish in stream appearance)

Source: Public Health Image Library, ID#:5324/Centers for Disease Control and Prevention (CDC) (*with permission*)

Culture

Cultural Conditions

V. cholerae is non-fastidious, grows well on ordinary media, such as—

- Nutrient agar (produces glistening translucent colonies with a bluish tinge in transmitted light) or
- Peptone water (produces uniform turbidity with formation of surface pellicle).

It is strongly aerobic (growth being scanty anaerobically). Other properties include:

- Hemodigestion: *V. cholerae* produces hemodigestion on blood agar which refers to the nonspecific killing of blood cells by metabolic by products of bacteria. This can be seen on a blood agar plate, as the medium surrounding the main inoculums turns green, but there is no change around single colonies (Fig. 31.4).
- It grows optimally at 37°C (range 16–40°C).
- Growth is better in alkaline medium. The optimum pH is 8.2 (range 7.4–9.6).
- NaCl (0.5–1%) stimulates the growth, however, high concentrations of NaCl (>6%) are inhibitory.

Culture Medium

To inhibit the commensals, fecal specimen should be inoculated simultaneously onto enrichment broth and selective media.

- Enrichment broths: They are incubated for 4–6 hours and thereafter a subculture is made onto another selective medium. Prolonged incubation of the broths should be avoided as the commensals may overgrow.
- Selective media: Stool specimen is directly inoculated on to a selective medium and the plate is incubated at 37°C for 24 hours.

Enrichment Broth

- **Alkaline peptone water (APW)** contains peptone, NaCl in distilled water at a pH of 8.6. Stool sample is inoculated into APW at 1:10 ratio.
- **Monsur's** taurocholate tellurite peptone water (pH 9.0).

Both can also be used as transport media.

Selective Media

- **Alkaline bile salt agar (BSA)** at pH **8.2:** This was the medium of choice in the past, still used in many laboratories. The colonies are typically glistening, **oil drop**, translucent type similar to those on nutrient agar.
- **Monsur's** gelatin taurocholate trypticase tellurite agar (GTTTA) medium: *V. cholerae* produces small (1–2 mm), translucent colonies with a **greyish black Center and a turbid halo**. The alkaline pH (8.5) and potassium tellurite are inhibitory to most of the commensals. Classical biotypes grow better on it than on TCBS agar.
- **TCBS agar:** It contains thiosulfate, citrate, bile salts (as inhibitor), sucrose and has pH of 8.6. Bromothymol blue and thymol blue are used as indicators. This is widely used at present (Fig. 31.5).
  - *V. cholerae* and other sucrose fermenting vibrios produce large (3–5 mm) yellow colored colonies; whereas sucrose non-fermenters (*V. mimicus* and *V. parahaemolyticus*) produce green colored colonies.
  - Though it is inhibitory to most of the bacteria, some strains of *Aeromonas, Proteus* and *Enterococcus* may occasionally grow.
- **MacConkey agar:** When not sure about the type of enteric pathogen present in feces, MacConkey agar can be included in the panel. As it is mildly selective, it also

Fig. 31.4: *Vibrio cholerae* on blood agar (hemodigestion)

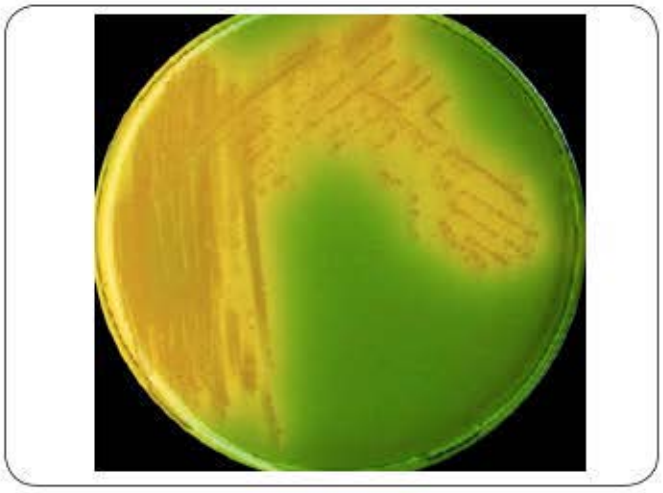

Fig. 31.5: TCBS agar with yellow colored colonies of *Vibri cholerae*

supports other enteric pathogens such as *Shigella* and *Salmonella*. Colonies of *V. cholerae* are translucent and pale which may become pink on prolonged incubation (due to late lactose fermentation).

Culture Smear and Motility Testing

- Culture smear of the colonies reveals short curved gram- negative bacilli. The typical comma-shaped bacilli arranged in fish in stream appearance, which is observed in smears made from fresh samples are often lost on repeat subcultures.
- Hanging drop shows typical darting motility.

Biochemical Reactions

V. cholerae shows the following biochemical properties:

- Catalase and oxidase positive
- **ICUT test:**
  - Indole test—positive
  - Citrate test—variable
  - Urease test—negative
  - TSI (triple sugar iron agar test)—shows acid/acid, gas absent, H_2S absent
- Nitrate reduction test is positive
- **Cholera red reaction:** Indole and nitrate reduction properties can be tested together by adding few drops of sulphuric acid to a peptone water culture of *Vibrio cholerae*. A reddish pink color nitroso-indole ring is formed.
- **MR** (methyl red) test—positive
- **VP** (Voges Proskauer) test—positive for El Tor, negative for classical biotype.
- **Sugar fermentation test:** *V. cholerae* ferments glucose, sucrose and mannitol with production of acid but no gas. Mostly, it does not ferment lactose except some strains that may ferment late.
- **String test:** When a colony of *Vibrio* is mixed with a drop of 0.5% sodium deoxycholate on a slide, the suspension loses its turbidity, and becomes mucoid. When tried lifting the suspension with a loop, it forms a string (Fig. 31.6).
- **Decarboxylase tests:** These can differentiate *Vibrio* from related genera *Aeromonas* and *Plesiomonas*:
  - *Vibrio* utilizes lysine and ornithine
  - *Aeromonas* utilizes only arginine
  - *Plesiomonas* utilizes all, i.e. lysine, arginine and ornithine.
- **Susceptible to O/129** (vibriostatic agent): *Vibrio* species are susceptible to 10 µg of O/129 disk while *Aeromonas* and *Plesiomonas* are resistant.
- **Salt tolerance test:** Peptone water broths with graded concentrations of NaCl are used to differentiate between *V. cholerae* from halophilic vibrios. *V. cholerae* tolerates maximum up to 6% NaCl.

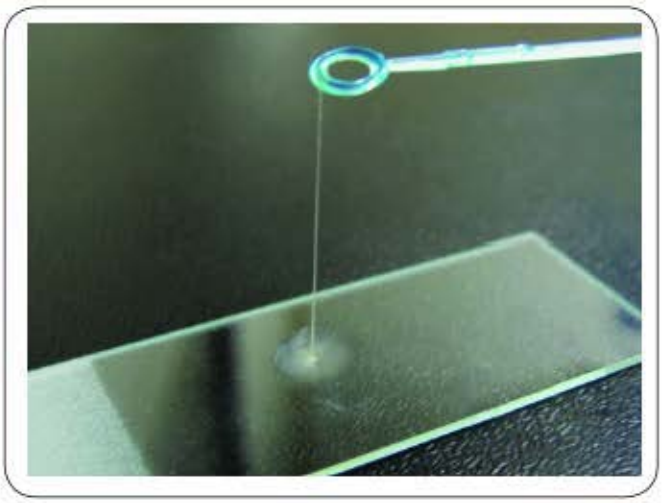

Fig. 31.6: String test

Biotyping

The classical and El Tor biotypes can be differentiated by various biochemical tests, susceptibility to polymyxin B and bacteriophages (refer Table 31.2).

Serogrouping

Species identification is always confirmed by agglutination test done on a slide with *V. cholerae* polyvalent O antisera.

- **Specific serogroups** can be identified by using group-specific antisera. First the colony is tested with O1 antisera→ If found negative, then tested with O139 antisera.
- **Serotyping**-If agglutinated with O1 antisera, then the serotyping is done by testing simultaneously with Ogawa and Inaba antisera.
  - If agglutinated with Ogawa antisera—it is designated as Ogawa serotype
  - If agglutinated with Inaba antisera—it is designated as Inaba serotype
  - If agglutinated with both Ogawa and Inaba antisera—it is designated as Hikojima serotype

Antimicrobial Susceptibility Testing

It is done on Mueller Hinton agar by disk diffusion test.

TREATMENT **Cholera**

- **Fluid replacement:** It is the most important measure for management of the cholera patient. It should be prompt and adequate to correct hypovolemia and thereafter to be maintained to replace the ongoing fluid losses.
  - **In mild to moderate fluid loss:** Oral rehydration solution (ORS) should be given.
  - **In severe cases:** Intravenous fluid replacement with Ringer's lactate (or normal saline) should be carried out till the consciousness arrives, thereafter replaced by ORS.

Contd...

Contd...

TREATMENT **Cholera**

- **Antibiotics** have a minor role as the pathogenesis is toxin mediated.
  - Although not necessary for cure, use of antibiotic may decrease the duration and volume of fluid loss and hastens clearance of the organism from the stool, thus prevents the development of carrier stage (Table 31.4).
  - The WHO recommends the use of antibiotics to only severely dehydrated patients, although wider use is not contraindicated.

Prevention

General Measures

General measures include:

- Provision of safe water
- Improved sanitary disposal of feces
- Proper food sanitation
- Prompt outbreak investigation and taking necessary steps to reduce transmission
- Notification: Cholera is a notifiable disease locally and nationally, hence the cases should be notified.
- Health education.

Chemoprophylaxis

Tetracycline is the drug of choice (Table 31.4). It is indicated to household contacts, only during epidemic. Mass chemoprophylaxis is not advised as the duration of protection is short.

Vaccine

Injectable Killed Vaccines

They are no longer in use, as they provide little protection, cause adverse effects and fail to induce a local intestinal mucosal immune response.

TABLE 31.4: Antibiotic therapy for cholera

	Drug of choice	Alternate drugs
Treatment of acute cases		
Adult	Doxycycline (single dose of 300 mg) or Tetracycline (12.5 mg/kg four times a day for 3 days)	Ciprofloxacin Erythromycin Azithromycin
Children/ pregnancy	Erythromycin or Azithromycin (10 mg/kg)	Cotrimoxazole
Chemoprophylaxis		
	Tetracycline (12.5 mg/kg four times a day for 3 days)	Doxycycline (single dose of 300 mg)

Oral Cholera Vaccines (OCV)

Oral cholera vaccines are currently in practice. Two types of oral vaccines are available.

Killed Whole-cell vaccine:

- Two preparations are available:
  1. Whole-cell (WC) vaccine: It is composed of killed whole cells of *V. cholerae* O1 (classical and El Tor, Inaba and Ogawa).
  2. Whole-cell recombinant B subunit cholera vaccine (WC/rBS) (Dukoral): Composition is same as that of WC vaccine, in addition it has recombinant cholera toxin B subunit.
- **Schedule:** Two doses are given orally, at 7 days gap except for children 2–5 years (3 doses). It is not licensed for children less than 2 years.
- **Protection** is short lived. For the first 6 months after vaccination, the protection rate is around 58% for WC vaccine and 85% for WC/rBS vaccine. However it falls rapidly to 50% by 3 years of vaccination.
- Children are better protected than adults.
- WHO recommends for using vaccine during epidemics and out breaks in the community but not during inter epidemic period.

Oral live attenuated vaccines (OCV): They use mutant strains that lack the gene encoding for cholera toxin.

- Several live OCV are under trial such as:
  - CVD 103-HgR, Peru-15 and *V. cholerae* 638 for classical and/or El Tor biotypes of *V. cholerae* O1.
  - CVD-112 and Bengal-15 vaccine trials are ongoing for *V. cholerae* O139.
- CVD 103-HgR vaccine (*Orochol*) contains a live attenuated strain derived from reference strain 569 B (classical, O1, Inaba), given as single dose. Its protection starts after 8 days.
- Use of OCV is recommended to limit the risk of:
  - Occurrence of cholera outbreaks in displaced populations in endemic areas.
  - Spread and incidence of cholera during an outbreak.

Non O1/O139 (O2-O138) *V. Cholerae*

They may resemble biochemically to *V. cholerae* O1/O139, but do not agglutinate with O1 or O139 antisera.

Clinically, they differ from O1/O139 strains as follows:

- **Gastroenteritis:** Several outbreaks of gastroenteritis following sea food consumption (raw oysters) have been reported from Mexico and other places.
  - Stool is watery or partly formed, less voluminous and bloody or mucoid.
  - Many cases have abdominal cramps, nausea, vomiting and fever.

- However, they never cause epidemic cholera.
- Treatment is same as that of cholera. Fluid replacement is the most crucial step. Antibiotics can be given in severe dehydration.

- **Extraintestinal manifestations:** Such as otitis media, wound infection and bacteremia (in patients with liver disease) have been reported sporadically.
  - Most of these infections are acquired by occupational or recreational exposure to seawater.
  - Antibiotics are often indicated. Most strains are sensitive to tetracycline, ciprofloxacin and third-generation cephalosporins.

HALOPHILIC VIBRIOS

Halophilic vibrios can withstand higher salt concentration (>6%) in contrast to *V. cholerae*, which can tolerate up to 6%. They are widespread in marine environments. Cases tend to occur during late summer and early rain fall, when the bacterial counts are highest in the water.

Vibrio parahaemolyticus

Though *V. parahaemolyticus* was first reported from Japan (1953), the incidence of infection has greatly increased in several countries including Japan since 1993. In India, it has been reported from Kolkata.

Clinical Manifestations

- Food-borne gastroenteritis is the most common presentation, occurs following raw or uncooked sea food (e.g. oyster) intake. It commonly presents as watery diarrhea or rarely as dysentery with abdominal cramps.
- Extraintestinal manifestations are rare, such as wound infection, otitis and sepsis.

Pathogenesis

Pathogenesis of *V. parahaemolyticus* is related to the presence of the following virulence factors:

- Polysaccharide capsule which prevents the bacilli from phagocytosis.
- Hemolysin (thermo-stable)
- Urease enzyme (in few strains): It breaks down urea from food to release ammonia that buffers gastric acidity.
- It possesses two type III secretion systems in cell wall, which directly inject toxic bacterial proteins into host cells.

Serotype: *V. parahaemolyticus* has 13 O somatic antigens and more than 60 K capsular antigens. Most of the infections are caused due to serotypes O3:K6, O4:K68, and O1:K-untypable.

Laboratory Diagnosis

Laboratory diagnosis of *V. parahaemolyticus* is carried out similar to that followed for *V. cholerae*. The distinct properties are as follows:

- Morphology: It is capsulated, shows bipolar staining in fresh isolates and pleomorphism in older cultures.
- Motile by peritrichous flagella (but it does not show darting motility).
- On TCBS, agar it produces green colonies (sucrose non-fermenter).
- **Kanagawa phenomenon:** It causes β hemolysis on Wagatsuma agar (a special type of high salt blood agar).
- Swarming: It swarms on blood agar.
- Urease test is positive in few strains.
- Salt tolerance test: It can resist maximum of 8% NaCl.

TREATMENT — ***V. parahaemolyticus***

- Most of the gastroenteritis is self-limiting and treatment is same as that of cholera.
- Severe gastroenteritis or extraintestinal manifestations are associated with underlying diseases, such as diabetes, preexisting liver disease, iron-overload states, or immunosuppression. They need antibiotic treatment, as described above for cholera.

Vibrio vulnificus

Though rare, *V. vulnificus* produces the most severe infection among the *Vibrio* species.

Clinical Manifestations

It can cause two distinct syndromes:

1. **Primary sepsis:** Usually occurs in patients with underlying liver disease and iron overload or rarely in renal insufficiency and immunosuppression.
2. **Primary wound infection:** It is characterized by painful erythematous swelling or cellultis or even vesicular, bullous or necrotic lesions, generally affects people without underlying disease (*Vulnificus* is Latin word for "wound maker").

Laboratory Diagnosis

V. vulnificus can be cultured from blood or cutaneous lesions. Key biochemical reactions include—

- Ferments lactose [the only lactose fermenting (L$^+$) *Vibrio*]
- Arginine is not dehydrolyzed.

TREATMENT — ***Vibrio vulnificus***

Early antibiotic institution, wound debridement, and general supportive care are the keys to recovery. *V. vulnificus* is sensitive in vitro to a number of antibiotics, including tetracycline, fluoroquinolones, and third-generation cephalosporins.

Vibrio alginolyticus

V. alginolyticus can occasionally cause eye, ear and wound infections.

- Few cases of otitis externa, otitis media and conjunctivitis have been reported.
- It rarely causes bacteremia in immunocompromised hosts.
- It is the most salt-tolerant *Vibrio* and can grow at salt concentrations of more than 10%.
- Disease is usually self limiting. Severe infections respond well to antibiotics (tetracycline) and drainage.

AEROMONAS

Aeromonas was earlier placed in the family Vibrionaceae; however, it has now been assigned to a separate family, Aeromonadaceae. *A. hydrophila* causes **red leg disease** in frog.

Pathogenicity of *Aeromonas* in humans is mainly related to:

- Tissue adherence mediated by adhesins such as S-layer and fimbriae.
- Capsular polysaccharide (prevents the bacilli from phagocytosis).
- Exotoxins, such as aerolysin, phospholipases, hemolysins, enterotoxin and cytotoxin similar to Shigatoxin.
- Endotoxin or LPS.

Clinical manifestations: Over 85% of the human infections are caused by *A. hydrophila*, *A. caviae* and *A. veronii*. Most of the other species are mainly isolated from environmental sources and animals. Various manifestations include:

- Gastroenteritis (watery diarrhea, vomiting, fever and rarely dysentery) and peritonitis
- Musculoskeletal and wound infections
- Bacteremia in immunocompromized adults and infants
- Respiratory tract infections, such as epiglottitis, pharyngitis and pneumonia
- Hemolytic uremic syndrome (HUS) due to production of enterotoxin similar to Shiga-S toxin.

Laboratory diagnosis: The Key identification features are:

- Motile with single polar flagellum
- MacConkey agar—produce non lactose fermenting pale colonies
- Oxidase and catalase positive
- Decarboxylase test—utilizes only arginine
- Growth is not stimulated by NaCl.

Genotypic classification: Recently the taxonomy of *Aeromonas* has changed a lot. DNA hybridization studies have established 12 genomic species or hybridisation groups (HG).

TREATMENT — ***Aeromonas***

Aeromonas is susceptible to cefotaxime and ciprofloxacin; however, the plasmid mediated drug resistance has been reported including β lactamase production.

EXPECTED QUESTIONS

I. Essay:

1. A 4-year-old boy developed severe watery diarrhea and vomiting. The stool collected has a rice water type of appearance. It was sent for bacteriological analysis.
   a. What is the probable etiological diagnosis of this condition?
   b. Describe in detail the pathogenesis of this condition?
   c. Add a note on its laboratory diagnosis.

II. Write short notes on:

1. Prophylaxis against cholera
2. Halophilic vibrios

III. Multiple Choice Questions (MCQs):

1. **Which of the following media can be used as transport medium for vibrios?**
   a. Selenite F broth
   b. Nutrient broth
   c. Tetrathionate broth
   d. Venkatraman–Ramakrishnan medium
2. **All of the following tests can differentiate between classical and El Tor biotypes of *V. cholerae* except:**
   a. β hemolysis on sheep blood agar
   b. Chick erythrocyte agglutination
   c. Growth on TCBS agar
   d. Polymyxin B (50 IU)
3. **Pathogenesis of *V. cholerae* involves one of the following second messenger systems:**
   a. cGMP
   b. cAMP
   c. Ca2+
   d. IP3
4. **Selective media for *Vibrio cholerae*:**
   a. TCBS
   b. Mannitol salt agar
   c. Robertson cooked meat medium
   d. Modified Thayer Martin medium
5. **All of the following *Vibrio* species are halophilic except:**
   a. *V. cholerae*
   b. *V. parahaemolyticus*
   c. *V. alginolyticus*
   d. *V. vulnificus*

CHAPTER 32

Pseudomonas and other Non-fermenters

Chapter Preview

- Pseudomonas species
- Other non-fermenters
  - Burkholderia species
  - Acinetobacter species
  - Stenotrophomonas maltophilia
  - Elizabethkingia meningosepticum
  - Moraxella lacunata
  - Alcaligenes species

Non-fermenters do not ferment any sugars, but they utilize the sugars oxidatively. Though the list is exhaustive, important human pathogens among non-fermenting gram-negative bacilli are *Pseudomonas, Burkholderia, Acinetobacter, Stenotrophomonas, Shewanella* and others.

PSEUDOMONAS

Pseudomonas is an oxidase positive, pigment producing, non-fermenting gram-negative bacilli. It is a major pathogen among the hospitalized patients and in patients with cystic fibrosis.

Virulence Factors and Pathogenesis

The pathogenesis of *Pseudomonas* is greatly attributed to its ability to develop widespread resistance to multiple antibiotics and disinfectants, and producing a number of virulence factors.

- **Colonization:** The first event to initiate the infection is to adhere and colonize the host surface. Various factors help in adhesion, such as pili or fimbria (the organ of attachment) and polar flagellum (mediates chemotactic motility to reach the host's surface).
- **Toxin-mediated immune evasion and tissue injury:** *Pseudomonas aeruginosa* produces probably the largest number of toxins and enzymes among the Gram-negative bacteria. These can be grouped into:
  - **Non diffusible toxins** (e.g. exotoxins S, U, T, and Y): Colonized *Pseudomonas* injects these toxins via a type III secretion system into the host cells, which allows the bacteria to evade the phagocytic cells and induce tissue injury by their cytotoxic activity.
  - **Diffusible toxins:** e.g. exotoxin A, proteases, phospholipases, hemolysins, elastases, pyocyanin, etc. They are secreted by the organism's type II secretion system, can act freely and mediate tissue injury.

    Exotoxin A: This is the most important virulence factor of *P. aeruginosa*. It inhibits protein synthesis by inhibiting elongation factor-2 (mechanism of action is similar to diphtheria toxin).
- **Host's inflammatory response:** Host elicits inflammatory responses as a defense mechanism against various components of the bacilli, such as endotoxin and flagellin, mediated through the Toll-like receptors (TLR 4 and 5). However, florid and stronger inflammatory responses can lead to tissue injury and septic shock.
- **Pigment production:** *Pseudomonas* produces a number of pigments which diffuse freely into the surroundings, inhibit other bacteria and mediate tissue injury.
  - Pyocyanin: It is a blue green pigment, produced only by *P. aeruginosa*
  - Fluorescein (or pyoverdin): It gives greenish yellow color, to the colony produced by most of the species
  - Pyorubin (impart red color)
  - Pyomelanin (impart brown black color)
- **Alginate coat**: Mucoid strains of *Pseudomonas* have a slime layer or alginate layer which facilitates biofilm formation, thus helps in adhesion to host cells and purulent mucus. Such strains can cause infections in patients with cystic fibrosis.
- **Capsule**: Many strains of *Pseudomonas* possess polysaccharide capsule, which prevents the bacteria from phagocytosis.
- **Multidrug resistance:** *Pseudomonas* is known to possess genes coding for resistance to several antimicrobial agents; thereby helping the bacilli to survive under antibiotic pressure especially in the hospital environment. Biofilm formation is another

mechanism by which it prevents the entry of antibiotics into the bacterial cell.

- **Multi-disinfectant resistance:** It helps the bacilli to grow in presence of various disinfectants; thus, spreading the infection in the hospitals.
- **Wide temperature range**: *Pseudomonas* survives in extremes of temperatures (5–45°C), which allows the bacilli to be ubiquitous.

Clinical Manifestations

Psuedomonas aeruginosa is notorious to cause infections at almost all sites, most common being lungs, skin and soft tissues. Most of the infections are encountered in hospitalized patients who get colonized with the organisms either from heavily contaminated hospital environment or from the hospital staff (through contaminated hands). Colonized patients develop disease in the presence of underlying risk factors such as burn wounds, patients with immunosuppression and post surgeries. The manifestations are as follows.

- **VAP** (ventilator associated pneumonia): It develops among patients on ventilator in intensive care units.
- **Chronic respiratory tract infections:** It occurs in patients with underlying conditions such as cystic fibrosis (in Caucasian populations), bronchiectasis or chronic panbronchiolitis (in Japan).
  - The mucoid strains (possessing alginate layer) of *Pseudomonas* commonly cause such infections.
  - Structural abnormalities of the airways result in mucus stasis.
  - Adherence to the mucus by the mucoid strains of *P. aeruginosa* initiates the infection. However, such strains lack most of the other virulence factors such as loss of O side chain of LPS.
- **Bacteremia** leading to sepsis and septic shock.
- **Infective endocarditis (native valves):** It occurs among IV drug abusers.
- **Ear infections:** The infections are either mild, such as **Swimmer's ear** (among children) or serious necrotizing form designated as **malignant otitis externa** (in elderly diabetic patients).
- **Eye infections** such as corneal ulcers (in contact lens wearers) and endophthalmitis secondary to bacteremia
- **Shanghai fever**: It is a mild febrile illness resembling typhoid fever.
- **Skin and soft tissue infections**
  - **Burns patients**: *Pseudomonas* is the most common organism to infect the burn wounds.
  - **Ecthyma gangrenosum**: It is an acute necrotizing condition resulting from bacteremia, occurs commonly in patients with febrile neutropenia and AIDS.
  - **Dermatitis** (folliculitis and other papular or vesicular lesions): It cause outbreaks in spas and swimming pools
  - Toe-web infections (in the tropics)
  - **Green nail syndrome:** It is a 'paronychia' (inflammation of the tissues adjacent to the nail with green pus formation). It results from prolonged submersion of the hands in water.
  - Cellulitis (characterized by **blue green pus**).
- **Other infections**
  - Bone and joint infections such as osteomyelitis and septic arthritis
  - Meningitis (in postoperative or post-traumatic patients)
  - UTI (urinary tract infection) in catheterized patients.

LABORATORY DIAGNOSIS — *Pseudomonas aeruginosa*

- **Sample collection:** Pus, wound swab, urine etc
- **Direct smear:** Gram negative bacilli, and pus cells
- **Culture:**
  - Nutrient agar: opaque, irregular colonies with metallic sheen (iridescence) and blue green diffusible pigments
  - Blood agar: β-hemolytic grey moist colonies
  - MacConkey agar: NLF colonies
  - Selective media: e.g. cetrimide agar
- **Culture smear and motility:** Motile, gram-negative bacilli
- **Biochemical identification:**
  - Catalase positive and oxidase positive
  - ICUT tests- Indole(–), Citrate (+), Urease(-), TSI:K/K, gas(–), H_2S
  - OF test shows oxidative pattern (non-fermenter)
- **Antimicrobial susceptibility testing**

Laboratory Diagnosis

Specimen

Various specimens such as pus, wound swab, urine, sputum, blood or CSF are collected; depending up on the site infected.

Direct Smear

Gram staining of the specimen shows plenty of pus cells and slender gram-negative bacilli (1.5–3 × 0.5 μm), occasionally capsulated, but no spores.

Culture

Pseudomonas is non-fastidious, can grow in ordinary media. It is an obligate aerobe, hence specimens after being inoculated onto various media, should be incubated aerobically, at 37°C for 24 hours.

- **Peptone water**: *Pseudomonas* forms uniform turbidity with a **surface pellicle** formation, due to more oxygen tension at surfaces.
- **Nutrient agar**: It produces large, opaque, irregular colonies with a metallic sheen (described as **iridescence**) (Fig. 32.1A).
  - **Pigments:** Most strains produce diffusible pigments which are either- blue green (pyocyanin), or yellow

green (pyoverdin). Some strains are non-pigmented. Pigment production can be enhanced in special media such as **King's media.**

- Most colonies have a characteristic sweet ether or alcohol-like **fruity odour**.
- **Morphotypes:** *Pseudomonas* colonies show various morphological appearances such as large spreading type, mucoid type, small round type, minute type, etc.

- **Blood agar:** It produces β hemolytic colonies on blood agar.
- **MacConkey agar:** It produces pale non-lactose fermenting colonies.
- Selective media such as **cetrimide agar** can be used to isolate the organism from mixed growth in purulent specimens.

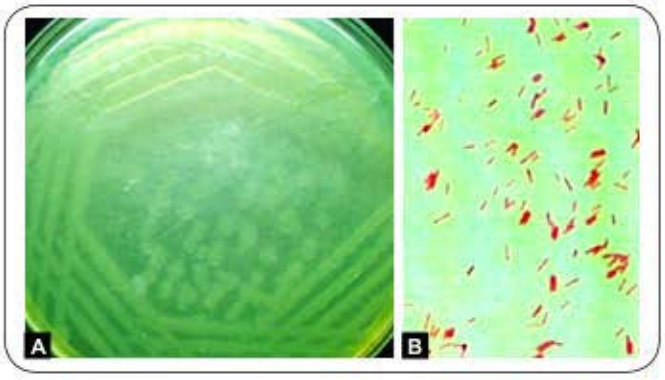
Culture Smear and Motility Testing

Culture smear shows gram-negative bacilli (Fig. 32.1B). They are actively motile with single polar flagellum.

Biochemical Properties

Pseudomonas aeruginosa shows the following features:

- Oxidase and catalase positive
- Non-fermenter: Does not ferment any sugars, but utilize sugars oxidatively.
- **OF test** (Hugh and Leifson oxidative fermentative test): The test shows oxidative pattern.
- **ICUT test:**
  - Indole test is negative
  - Citrate test: positive
  - Urease test: Negative
  - Triple sugar iron (TSI) test: The test shows alkaline slant/alkaline butt (no change), with no gas and no H_2S.



Figs 32.1A and B: A. Large, opaque, irregular colonies of *Pseudomonas aeruginosa* with a metallic sheen and green color pigmentation; **B.** Gram stained culture smear of *Pseudomonas* showing gram-negative bacilli

Antimicrobial Susceptibility Testing (AST)

AST is essential to administer proper antibiotics. It is done on Mueller–Hinton agar by disk diffusion method.

Typing Methods

P. aeruginosa is an important cause of hospital-acquired infections, it is essential to type the isolates beyond the species level, to find out the relatedness between the isolates. This is useful during outbreaks, to trace the source of infection. For epidemiological studies, various typing methods are used such as:

- **Bacteriocin (pyocin) typing:** It is based on the ability of the strain producing distinct bacteriocin that inhibits certain indicator bacterial strains.
  - *P. aeruginosa* produces three types of bacteriocins (or pyocins) known as **R, F** and **S.**
  - Depending upon the growth inhibition of indicator strains by pyocins, 105 types have been recognized.
- **Antibiogram typing:** It is based on the antimicrobial resistance pattern of the strains. It is the easiest and most commonly used method in hospitals.
- **Serotyping:** It is based on O and H antigens, 17 serotypes of *P. aeruginosa* have been recognized.
- **Molecular methods:** These methods, such as pulse field gel electrophoresis (PFGE) have highest discriminatory power to differentiate between the strains. However, their use is limited only to reference laboratories.

TREATMENT ***Pseudomonas***

Pseudomonas species are inherently resistant to most of the antibiotics. Only limited antimicrobial agents have antipseudomonial action, such as:

- **Penicillins:** Piperacillin, mezlocillin, ticarcillin
- **Cephalosporins:** Ceftazidime, cefoperazone and cefepime
- **Carbapenems:** Imipenem, meropenem
- **Monobactam:** Aztreonam
- **Aminoglycosides:** Tobramycin, gentamicin, amikacin
- **Quinolones:** Ciprofloxacin, levofloxacin
- **Polymyxins:** Polymyxin B, colistin

Drug Resistance

Pseudomonas possesses a number of drug resistant plasmids which confer resistance to several antibiotics. Many strains are producers of β lactmases, such as ESBL (extended spectrum β lactamases), carbapenemases, and AmpC β lactamases. Many strains are resistant to aminoglycosides and quinolones.

OTHER NON-FERMENTERS

Burkholderia

Burkholderia species are also oxidase positive non-fermenters similar to *Pseudomonas*; however, they differ from the latter in being:

- Bipolar stained (safety pin appearance)
- Resistant to polymyxin B

Burkholderia pseudomallei (Melioidosis)

B. pseudomallei is the causative agent of melioidosis.

- **Habitat:** *B. pseudomallei* is a saprophyte of soil and water and have large number of animal reservoirs. Melioidosis also occurs in rats, rabbits and guinea pigs.
- **Mode of transmission:** Humans and animals are infected by various routes such as inoculation, inhalation or ingestion. Man to man transmission is very rare.
- **Virulence factors:** *B. pseudomallei* is perhaps the most virulent among the non-fermenters. Several virulence factors are described such as polysaccharide capsule, type III secretion system, LPS, toxins and enzymes.
- **Clinical features:** Melioidosis is characterized by:
  - Pulmonary infection: Ranges from abscesses, pneumonia to severe necrotizing lungs disease. Some patients present with chronic pulmonary infection that mimics tuberculosis.
  - Skin ulceration
  - Lymphadenopathy
- **Long latent period:** Manifestations are exacerbated long after the exposure; hence melidiosis is also known as **'Vietnam time-bomb disease'**.
- **Bioterrorism:** *B. pseudomallei* can be used as a potential agent of biological warfare.
- **Geographical distribution:** Melidiosis is restricted to Southeast Asia and northern Australia. In India, melioidosis has been reported from many states such as Tamil Nadu, Maharashtra, Orissa, West Bengal, Pondicherry and Kerala.
- **Laboratory diagnosis**
  - **Specimen:** It depends on the site of infection, various specimens are collected such as sputum, purulent discharge from lesion, etc.
  - **Direct microscopy:** They are gram-negative bacilli that typically exhibit a **bipolar or safety pin** appearance (Fig. 32.2), which is better appreciated when stained with methylene blue.
  - **Culture:** *B. pseudomallei* is an obligate aerobe, grows in various media, e.g. nutrient agar, blood agar and MacConkey agar. Colonies are typically rough and corrugated, similar to the colonies of *Pseudomonas stutzeri*. **Ashdown's medium** is used as a selective medium, where it produces wrinkled purple colonies (Fig. 32.3).
  - **Biochemical reactions:** Important properties that differentiate it from *Pseudomonas stutzeri* include:
    - Gelatin liquefaction positive
    - Utilizes arginine
    - Positive for intracellular poly β hydroxy butyrate
  - **Latex agglutination test**: Cultures can be confirmed by latex agglutination test using specific antisera.

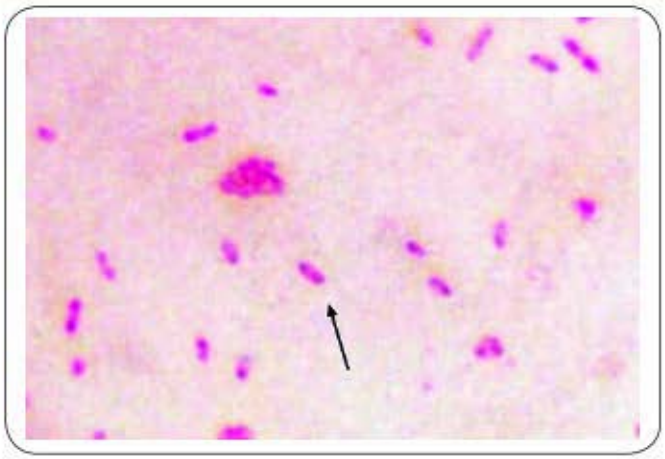


Fig. 32.2: Gram-stained smear of *Burkholderia pseudomallei* shows gram-negative bacilli (bipolar or safety pin appearance) (arrow showing)

Fig. 32.3: Wrinkled purple colonies of *Burkholderia pseudomallei* on Ashdown's medium

TREATMENT — Melioidosis

Treatment of melioidosis consists of:

- **Intensive phase** (2 weeks): Ceftazidime or a carbapenem is given followed by;
- **Maintenance phase** (12 weeks): Oral cotrimoxazole is given to eradicate the bacilli and prevent relapse.

Burkholderia mallei

B. mallei is a pathogen of horses; where it causes **glanders** (nasal discharge and ulcers in the nasal septum) and **farcy** (skin lesions and lymph node involvement).

- **Transmission:** Unlike other species, *B. mallei* is not an environmental organism. It is strictly zoonotic, transmitted from horses to man either by direct inoculation or inhalation.

- **Human infection** is characterized by:
  - Local skin nodules and lymphadenitis (if transmitted by inoculation)
  - Pneumonia , ulceration of the trachea and sepsis (if transmitted by inhalation)
- **Laboratory diagnosis:** It is similar to that of *B.pseudomallei*. However, *B.mallei* differs from *B.pseudomallei* in being:
  - Non-motile
  - Oxidase negative
  - Inability to grow on MacConkey agar
  - Does not grow at 42°C

  Strauss reaction: It has been seen that intra-peritoneal inoculation of *B.mallei* into guinea pigs can cause testicular swelling.
- **Treatment:** It is same as that of *B. pseudomallei*.

Burkholderia cepacia

B. cepacia is currently the most commonly encountered *Burkholderia* species.

- It is an environmental organism that inhabits moist environments, detergents and IV fluids.
- It has been recognized as a plant pathogen causing onion rot (cepia, Latin for onion).
- **Typing**: Based on DNA hybridization study, the organism has been typed into nine subgroups or genomovars, of which **type III and II** are associated with most of the cases of cystic fibrosis.
- **Virulence factors:** It possesses multiple virulence factors, such as:
  - Cable pilus: A type of fimbriae which is capable of binding to lung mucus
  - Elastase
  - Possesses secretion system like that of *P. aeruginosa*
  - LPS of *B. cepacia* is among the most potent of all bacteria; stimulates inflammatory response in the lungs.
- **Various manifestations** include:
  - **Cepacia syndrome**: It is characterized by a rapidly fatal respiratory infection and septicemia in patients with cystic fibrosis.
  - **Nosocomial pathogen**: It is resistant to multiple antibiotics, hence has been emerging as an important nosocomial pathogen in ICUs causing pneumonia, wound infections etc.
- **Laboratory diagnosis:** Clinical and environmental specimens can be inoculated on selective media. Optimum growth occurs at 30°C. Biochemical reactions can be carried out to differentiate the genomospecies.

TREATMENT ***Burkholderia cepacia***

B. cepacia is intrinsically resistant to many antibiotics. Therefore, treatment must be based on the sensitivity report. Cotrimoxazole, meropenem, and doxycycline are the most effective agents.

Acinetobacter

Acinetobacter are saprophytic bacilli, present in the environment (soil, water and phytosphere). However, during the last two decades, it has gained increasing attention as a nosocomial pathogen.

- **Genomospecies**: DNA hybridization studies have shown that *Acinetobacter* can be grouped into several genomospecies (currently, up to 25). The commonly isolated species are:
  - *A.baumannii* (genomospecies 2): It is the most pathogenic species.
  - *A.calcoaceticus* (genomospecies 1): It is a soil saprophyte.
  - *A. lwoffii:* It is a commensal (genomospecies 8).
- **Sources:** Hospital environment is heavily contaminated with these organisms. They are commensals in skin, oral cavity and intestine. The carriage rate is much higher among hospital staff than community.
- **Promote colonization:** Unhygienic practices in hospitals (contaminated hands of staff) and warm hospital environment (summers) promote colonization. Patients with underlying diseases or immunosuppression are predisposed to invasion and pathogenesis.
- **Pathogenesis:** It is not fully understood.
  - **Multidrug resistance:** Its ability to develop drug resistance rapidly to almost all available antibiotics makes it dangerous in hospital settings.
  - **Various virulence factors** are also attributed to pathogenesis such as:
    - Outer membrane protein A (OmpA): It mediates adhesion, invasion and cytotoxicity through mitochondrial damage.
    - LPS: It induces inflammatory responses that leads to tissue injury
    - Ability to form biofilm
    - Siderophores (help in iron acquisition)
- **Clinical manifestations:** *A. baumannii* causes widespread hospital infections such as:
  - Ventilator associated pneumonia
  - Central line associated bloodstream infection
  - Post-neurosurgical meningitis
  - Catheter- associated UTI
  - Wound and soft tissue infections
  - Infections in burn patients
- **Epidemiology:** Several hospital outbreaks due to *Acinetobacter* have been reported throughout the world.
- **Laboratory diagnosis:** It is an obligate aerobe, grows well on ordinary medium. Specimens can be inoculated onto blood agar (non-hemolytic colonies) and MacConkey agar (lactose non-fermenting pale colonies). Important characteristic biochemical properties are:

TABLE 32.1: Differences between *A. baumannii* and *A. lwoffii*

Properties	*A. baumannii*	*A. lwoffii*
Citrate	Positive	Negative
At 42°C	Grows	No growth
Oxidative–fermentation test (OF) glucose	Shows oxidative pattern	Asaccharolytic
10% lactose	Can ferment	Cannot ferment

- **Gram staining:** They are gram-negative coccobacilli, arranged singly or in pair, or chain. However, often they appear gram variable or even gram-positive.
- Oxidase negative and catalase positive
- Non-motile
- Non-fermenter, utilizes the sugars oxidatively
- TSI (triple sugar iron agar test) shows alkaline slant/alkaline butt with no gas and no H_2S.
- Negative for indole and urease test
- *A. baumannii* can be differentiated from *A. lwoffii* by various properties (Table 32.1).

- **Prevention:** Infection control measures such as improved hand hygiene are essential to prevent nosocomial infections due to *Acinetobacter*.

TREATMENT ***Acinetobacter***

Acinetobacter is notorious to develop resistance to multiple drugs including β-lactams, aminoglycosides and quinolones.

- β lactam resistance can be attributed to production of β lactamases such as metallo β lactamases (MBL), AmpC β lactamases and OXA-type β lactamases. Choice of antibiotics should always be based on susceptibility reports.
- Common antibiotics indicated are fluoroquinolones, carbapenems, amikacin, tigecycline and colistin.

STENOTROPHOMONAS MALTOPHILIA

S. maltophilia is a saprophyte found in the rhizosphere (soil surrounding the plant roots).

- **Colonization:** The organism is acquired from the environment which is favoured by:
  - Immunocompromised conditions
  - Patients on broad-spectrum antibiotics
- **Pathogenesis**: It is mediated by the host's inflammatory response to components of the organism such as LPS and flagellin. Virulence factors of the organism appear to be limited.
- **Drug resistance:** It is resistant to most of the antibiotics. β-lactam resistance is efflux pump mediated.
- **Clinical manifestations**: *S. maltophilia* can cause various hospital infections such as pneumonia in ventilated patients, blood stream infections and ecthyma gangrenosum in neutropenic patients.
- **Laboratory diagnosis:** It is a non-fermenter that is oxidase negative, motile and utilizes glucose, maltose and lactose oxidatively and decarboxylates lysine.

TREATMENT ***Stenotrophomonas maltophilia***

S. maltophilia is intrinsically resistant to most antibiotics. The recommended antibiotics are cotrimoxazole, ticarcillin/clavulanate and levofloxacin.

Elizabethkingia Meningosepticum

It was formerly called *Chryseobacterium* or *Flavobacterium*.

- **Manifestations:** It is saprophyte in soil, water and hospital environment. However, it causes nosocomial infections in patients with underlying immunosuppression such as:
  - Neonatal meningitis
  - Pneumonia, sepsis, endocarditis, bacteremia and soft tissue infections.
- **Laboratory diagnosis**
  - It is a non-motile, gram-negative bacillus
  - Nonfermenter: It utilizes sugar oxidatively
  - Produces **yellow non-diffusible pigment**
  - Does not grow on MacConkey agar, but grows on nutrient agar
- **Treatment:** It is susceptible to fluoroquinolones and cotrimoxazole; however β lactams should be given with caution as it produces β lactamases.

Alcaligenes

Alcaligenes faecalis and *Alcaligenes xylosoxidans* (renamed as *Achromobacter xylosoxidans*) are commensals of human intestine and saprophytes in variety of water sources, including well water, and humidifiers; sometimes found as contaminants in IV fluids.

- They are asaccharolytic (however, *A. xylosoxidans* utilizes sugars oxidatively), motile and produce thin spreading irregular colonies.
- They occasionally cause nosocomial outbreaks and pseudo outbreaks (may be a contaminant in culture) in immunocompromised hosts causing acute otitis, UTI and bacteremia.

EXPECTED QUESTIONS

I. Write short notes on:

1. Virulence factors of *Pseudomonas aeruginosa*
2. Melioidosis
3. Medically important nonfermenters

II. Multiple Choice Questions (MCQs):

1. Ecthyma gangrenosum is caused by:
a. *Pseudomonas* b. *Bordetella*
c. *Brucella* d. *H. influenzae*

2. Drugs used in *Pseudomonas* treatment:
a. Cefixime b. Ceftazidime
c. Ampicillin d. Cotrimoxazole

3. Cause of melioidosis is:
a. *Burkholderia mallei*
b. *Burkholderia pseudomallei*
c. *Burkholderia cepacia*
d. None

Answers

1. a **2.** b **3.** b

CHAPTER 33

Haemophilus and HACEK Group

Chapter Preview

- Haemophilus
  - Haemophilus influenzae
  - Haemophilus ducreyi
  - Haemophius aegyptius
- Other Haemophilus species
- HACEK group

HAEMOPHILUS

Haemophilus species are oxidase positive, capsulated pleomorphic gram-negative bacilli that require special growth factors present in blood, such as factor X and V (*Haemo* means blood, *philus* means loving). The important species are:

- *H. influenzae:* It is the most pathogenic species, which causes pneumonia and meningitis in children.
- Other species encountered are as follows (Table 33.1)
  - *H. ducreyi:* It causes a sexually transmitted disease called **chancroid,** which presents as genital ulcer.
  - *H. aegyptius*: It causes conjunctivitis and rashes
  - *H. haemolyticus* and *H. parahaemolyticus* produce hemolysis on blood agar
  - *H. aphrophilus* and *H. paraphrophilus*
  - *H. parainfluenzae*

HAEMOPHILUS INFLUENZAE

H. influenzae is also called **Pfeiffer's bacillus** as it was discovered by Pfeiffer (1892). The species name was coined wrongly, thinking that it would cause human influenza which is actually a viral disease caused by influenza virus.

TABLE 33.1: Growth characteristics of various *Haemophilus* species

Haemophilus species	Growth requirements			
	X	V	CO_2	Hemolysis on blood agar**
H. influenzae	+	+	–	–
H. aegyptius	+	+	–	–
H. haemolyticus	+	+	–	+
H. ducreyi	+	–	V*	V*
H. aphrophilus	+	–	+	–
H. parainfluenzae	–	+	–	–
V. parahaemolyticus	–	+	–	+
H. paraphrophilus	–	+	+	–

*V, variable; **, horse blood agar

Growth Requirements

H. influenzae requires two accessory growth factors present in blood.

1. **Factor X:** It consists of group of heat-stable compounds such as hemin or other porphyrins required for the synthesis of enzymes such as cytochrome, catalase and peroxidase; involved in the aerobic respiration. It is not required when *H. influenzae* grows anaerobically.
2. **Factor V:** It is a heat-labile, nicotinamide adenine dinucleotide (NAD), which is also produced by some animals, plant cells and other bacteria, such as *Staphylococcus aureus*. It was so named as it was thought to be a vitamin. It gets inactivated by NADase present in sheep blood.

The growth of *H.influenzae* vary in different media depending on the availability of X and V factors.

- **Does not grow on ordinary media:** Nutrient agar or peptone water lack X and V factors, hence does not support *Haemophilus* growth.
- **Growth is scanty on blood agar:** It is because only factor X is available in this medium and V factor is largely intracellular, present only inside the RBCs. It is available in very minute quantities freely in the medium. More so, sheep blood contains NADase that destroys factor V.
- **Grows well on chocolate agar:** While preparing chocolate agar, blood is poured into molten agar at 75°C which inactivates NADase and lyses RBCs releasing excess of factor V. Hence it supports the growth of *H. influenzae*.

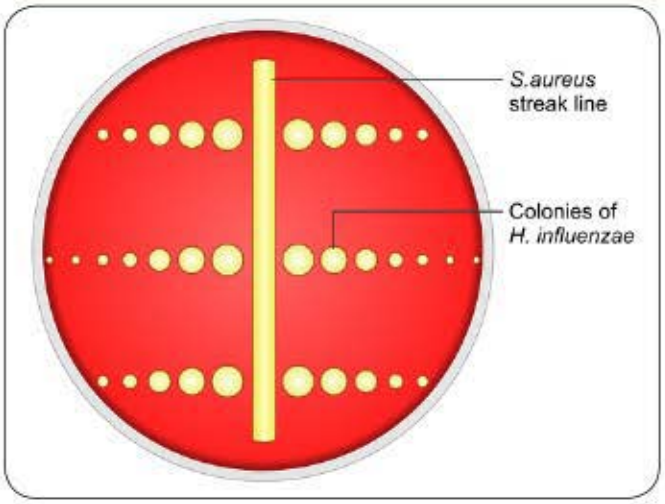

Fig. 33.1: Satellitism of *Haemophilus influenzae* (schematic diagram)

- **Satellitism:** It is observed that, *H. influenzae* can grow on blood agar if the source of V factor is provided (see the box below).

Satellitism

- When *S. aureus* is streaked across a blood agar plate perpendicular to the *H. influenzae* streak line, factor V is released from *S. aureus*. Hence, it forms larger colonies adjacent to *S. aureus* streak line and size of the colonies decreases gradually away from the *S. aureus* streak line.
- This phenomenon is called **satellitism**, a property that is routinely employed for the isolation of *H. influenzae* (Figs 33.1 and 33.2A).

Serotyping

Based on the capsular polysaccharide of *H.influenzae*, it can be typed into six serotypes (a to f). However, some strains lack capsule and are referred to as nontypeable strains.

- *H. influenzae* serotype b (*Hib*) is the most virulent among all types and accounts for most of the invasive infections.
- Hib capsule has a unique chemical structure, made up of polyribosyl ribitol phosphate (PRP) antigen. It is strongly immunogenic, induces IgG, IgM and IgA antibodies which are bactericidal, opsonic and protective. Hence, PRP antigen is used for vaccination.
- Next to Hib, non-typeable strains are commonly isolated clinically. Other capsular serotypes are very rarely isolated.
- *H. influenzae* was the first free-living organism whose entire genome was sequenced.

Virulence Factors

Various virulence factors of *H. influenzae* are:

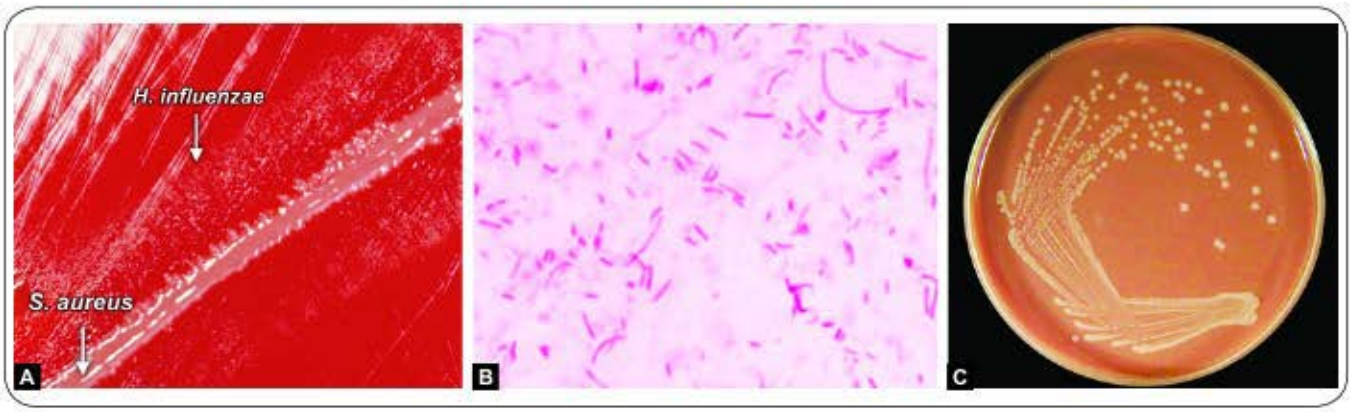
- Capsular polysaccharide is the most important virulence factor, acts by inhibiting phagocytosis.
- Endotoxin: It induces host's inflammatory response.
- Outer member proteins
- IgA 1 proteases: They inactivate IgA 1 present on the mucosal surface.
- Pili and other adhesion proteins: They are present in all strains including the non-typeable strain, which help in colonization on epithelial surface.

Clinical Manifestations

H. influenzae Type B (Hib)

Hib is the most common and most invasive serotype of *H. influenzae*, causes serious manifestations.

- **Central nervous system infections:**
  - Pyogenic meningitis: It mainly occurs in children less than 2 years of age; characterized by fever, neck rigidity, vomiting, headache and altered sensorium.
  - Subdural effusion: It is a common complication following meningitis, characterized by seizures or hemiparesis.



Figs 33.2A to C: A. Satellitism: *H. influenzae* satelliting around *S. aureus* streak line; **B.** *H. influenzae* in Gram-stained smear (pleomorphic gram-negative bacilli); **C.** Colonies of *H. influenzae* on chocolate agar

Source: A. Public Health Image Library, ID# 1047/Dr. Mike Miller/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Mortality rate is high if untreated. Survivors develop neurologic sequelae, such as partial hearing loss and delayed language development.

- **Epiglottitis:** It is a cellulitis of the epiglottis and supraglottic tissues. It is life threatening as it can lead to acute airway obstruction. It typically affects older children (2–7 years old) and rarely adults.
- **Pneumonia in infants:** It is clinically similar to other types of bacterial pneumonia except that, pleural involvement is more common in Hib infection.
- **Less common** invasive conditions seen in children include:
  - Cellulitis of neck and head region
  - Osteomyelitis, septic arthritis
  - Pericarditis
  - Orbital cellulitis, endophthalmitis
  - Urinary tract infection
  - Bacteremia without an identifiable focus.

Nontypeable H. influenzae

Next to Hib, non-typeable strains are the most common group encountered clinically. They are noninvasive, spread by contagious spread and usually affect adults. The clinical manifestations include:

- Childhood otitis media
- Exacerbations of chronic obstructive pulmonary disease (COPD): They are the most common bacterial cause for this condition.
- Pneumonia in adults with underlying COPD or AIDS.
- Puerperal sepsis and neonatal bacteremia: These infections are caused mainly by non-typeable strains of *biotype IV* that usually colonize the female genital tract.
- Sinusitis in adults and children
- Rarely they cause invasive infections, especially in countries where Hib vaccines are used widely. The differences between Hib and non-typeable *Haemophilus* strains are tabulated in Table 33.2.

TABLE 33.2: Differences between type b and nontypeable *Haemophilus* strains

Features	Type b strains	Nontypeable strains
Capsule	Made up of poly ribosyl ribitol phosphate (PRP)	Noncapsulated
Manifestations	Invasive—meningitis, epiglottitis, pneumonia, bacteremia, endocarditis	Noninvasive—otitis media (in children) and pneumonia (adult)
Age	Affect children	Affect adult
Spread	Hematogenous spread	Contiguous spread
Vaccine	Hib vaccine is available	Not available

LABORATORY DIAGNOSIS — *Haemophilus influenzae*

- **Specimens:** CSF, blood, sputum
  - Processed immediately, should never be refrigerated
- **Direct examination:**
  - Pleomorphic gram-negative coccobacilli
  - Capsule detection: By Quellung reaction,
  - Antigen detection: By latex agglutination test, direct-IF
- **Culture:**
  - Blood agar with *S. aureus* streak line shows satellitism
  - Chocolate agar: Fildes agar and Levinthal's agar
- Biochemical tests: Disk test for X and Y requirement
- Biotyping (indole, urease and ornithine test)
- Serotyping (using specific antisera)
- Antimicrobial susceptibility testing

Laboratory Diagnosis

Specimen Collection and Transport

- Depending upon the site of infection, various specimens may be collected such as cerebrospinal fluid (CSF), blood, sputum, pus, aspirates from joints, middle ears or sinuses.
- As *H. influenzae* is highly sensitive to low temperature, the specimens **should never be refrigerated**.
- The specimens should be transported to the laboratory without any delay and processed immediately.

Direct Detection

- **Gram staining** of CSF and other specimen shows pleomorphic gram-negative coccobacilli (Fig. 33.2B).
- **Capsule detection** (Quellung reaction): Capsular swelling occurs when a drop of CSF is mixed with type b antiserum and methylene blue and observed under microscope.
- **Antigen detection:** The type b capsular antigen can be detected in CSF, urine or other body fluids by—(1) latex agglutination test using latex particles coated with antibody to type b antigen or (2) by direct-IF test.

Culture

- **Cultural conditions:** *H. influenzae* is highly fastidious, requires the presence of factor X and V in blood. It is largely aerobic and growth is poor anaerobically. Growth is enhanced by 5–10% CO_2.
- **Culture media used are as follows:**
  - Blood agar with *S. aureus* streak line: Colonies of *H. influenzae* grow adjacent to *S. aureus* streak line **(satellitism)** (Figs 33.1 and 33.2A).
  - Chocolate agar: It grows well on chocolate agar but sparsely on blood agar (Fig. 33.2C).
  - **Fildes agar and Levinthal's agar:** These are transparent media used for *Haemophilus* (produces iridescent colonies). Here, the RBCs are lysed and NADase is inactivated by—(1) adding peptic digest (Fildes agar) or (2) by heat (Levinthal's agar).
  - ***Haemophilus* selective medium:** It media contains bacitracin (selective only for *Haemophilus)* and

sucrose (differentiates *H. influenzae* from *H. parainfluenzae*, the later ferments sucrose)

Culture Smear and Motility Testing

Gram staining of culture isolates reveals pleomorphic gram-negative non motile bacilli.

Biochemical Tests

- Catalase positive and oxidase positive
- Reduces nitrate to nitrite
- Ferments glucose and xylose but not sucrose, lactose and mannitol
- **Disk Test for X and V Requirement:** Growth is detected surrounding X, V, and XV discs on the medium lacking X and V factors. *Haemophilus* species vary in their X and V requirement. This property can be exploited for speciation (Table 33.1).
  - Growth surrounding X disc only: *H. ducreyi* and *H. aphrophilus*
  - Growth surrounding V disc only: *H. parainfluenzae, V. parahaemolyticus* and *H. paraphrophilus*
  - Growth surrounding on XV disk only: *H. influenzae, H. aegyptius* and *H. haemolyticus*

Typing Methods

- **Biotyping:** Strains are typed based on three biochemical properties (IOU test -indole, ornithine decarboxylase and urease).
  - *H. influenzae* has eight biotypes (I–VIII)
  - Most of the clinical isolates belong to type I, II and III
  - Majority of invasive type b strains belong to biotype I
- **Serotyping:** It is carried out by using type-specific antisera.

Antimicrobial Susceptibility Testing

It is done on Fildes' agar or chocolate agar.

TREATMENT — ***Haemophilus influenzae***

- Invasive infections due to *Haemophilus influenzae* type b cephalosporins, such as ceftriaxone, cefotaxime are the drug of choice.
- Nontypeable strains of *H. influenzae* are often resistant to β lactams [due to β-lactamase production (20–35% of strains) or rarely by expressing altered penicillin binding protein-3]. Those strains are usually susceptible to quinolones (levofloxacin) and macrolides (azithromycin).

Prophylaxis

Hib Conjugate Vaccine

The polyribosyl ribitol phosphate (PRP) capsular antigen of *H. influenzae* type b is used for vaccination.

- As capsular antigens are poorly immunogenic to children, they are conjugated with adjuvants such as diphtheria toxoid, tetanus toxoid and *N. meningitidis* outer membrane proteins.
- In addition to eliciting protective antibody, this vaccine can also reduce the rate of pharyngeal colonization with Hib.
- The widespread use of conjugate vaccines has dramatically reduced the incidence of Hib disease in the developed countries.

Chemoprophylaxis

Oral rifampin is the drug of choice. It is indicated to:

- Household contacts or
- Health care workers (if two or more cases occur in the hospital within 60 days)

OTHER HAEMOPHILUS SPECIES

Haemophilus ducreyi

Haemophilus ducreyi is an etiologic agent of **chancroid (or soft chancre)**, a sexually transmitted disease characterized by:

- Painful genital ulceration (Fig. 33.3) that bleeds easily; no inflammation of the surrounding skin
- Enlarged, tender inguinal lymph nodes (bubo)

Incubation period of 4–7 days. There is no immunity following the infection, however, hypersensitivity may develop.

Epidemiology

Chancroid is a common cause of genital ulcers in developing countries.

- Transmission is predominantly heterosexual
- Males to females ratio is about 3:1 to 25:1
- Chancroid and HIV: Chancroid increases both the efficiency of transmission and the degree of susceptibility to HIV infection.

Fig. 33.3: Chancroid (painful ulcer)

Source: Public Health Image Library, ID# 15567/ Dr. Pirozzi/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Laboratory Diagnosis

- **Specimens:** Exudate or swab from the edge of the ulcer and lymph node aspirate are the useful specimens.
- **Direct microscopy:** *H. ducreyi* is a pleomorphic gram-negative coccobacillus; occurs in groups or in parallel chains.
  - They frequently take bipolar staining.
  - The arrangement has been described as **school of fish** or **rail road track** appearance.
- **Culture:** *H. ducreyi* requires factor X (hemin), but not factor V for its growth. Primary isolation is difficult. It can be grown on—
  - Rabbit blood agar or chocolate agar enriched with 1% isovitalex and made selective by adding vancomycin
  - It may also be grown on chorioallantoic membrane of the chick embryo.
- **Optimum conditions** required for isolation are 10% CO_2, high humidity and incubation at 35°C for 2–8 days.
- **Colony morphology:** Colonies are small, grey, translucent, 1–2 mm in size in 2–3 days.
- **Biochemical reactions:** *H. ducreyi* is biochemically inert. Growth surrounding X disk can be used for presumptive diagnosis.
- **Slide agglutination test:** *H. ducreyi* is antigenically homogeneous and cultures can be confirmed by agglutination with the antiserum.
- A **multiplex PCR** assay has been developed for simultaneous detection of common agents of STDs such as *H. ducreyi*, *Treponema pallidum* and herpes simplex virus.

TREATMENT — ***Haemophilus ducreyi***

- Drug of choice: Azithromycin (1 g oral; single dose)
- Alternative drugs: Ceftriaxone, ciprofloxacin or erythromycin
- Treatment of all the sexual partners is essential

Haemophilus aegyptius

It is also called **Koch-Weeks bacillus**; closely resembles *H. influenzae* biotype III. However, it differs from the latter in having more predilection for conjunctiva and not occurring as pharyngeal carrier.

- *Haemophilus aegyptius* causes:
  - Purulent contagious conjunctivitis (Egyptian ophthalmia)
  - **Brazilian purpuric fever:** A fulminant condition, characterized by fever, purpura, hypotension and shock
- It requires both factors X and V, similar to *H. influenzae*, but differs from the latter by—
  - Fails to ferment xylose
  - Shows hemagglutination with guinea pig RBC at 4°C.
  - Slower growth than *H. influenzae*

Haemophilus parainfluenzae

It is a commensal in mouth and throat.

- Occasionally, it can be an opportunistic pathogen causing endocarditis, conjunctivitis and bronchopulmonary infections in patients with cystic fibrosis.
- It differs from *H. influenzae* by:
  - Requires only factor V, but not X
  - Ferments sucrose, but not xylose

H. haemolyticus and H. parahaemolyticus

They are also commensals in throat (both) or mouth (*H. parahaemolyticus* only).

- They differ from *H. influenzae* in being β hemolytic, which is best produced in sheep or ox blood agar and when incubated aerobically.
- *H. parahaemolyticus* is a rare cause of endocarditis.
- *H. haemolyticus* requires both factors X and V, where as *H. parahaemolyticus* requires only factor V.

Haemophilus aphrophilus and H. paraphrophilus

They are capnophilic and require 5–10% of CO_2 for optimum growth.

- *H. aphrophilus* requires only factor X, whereas *H. paraphrophilus* requires only factor V.
- They are commensals of mouth and occasionally cause endocarditis, head and neck infections, invasive bone and joint infections.

HACEK GROUP

HACEK is an abbreviation used to represent a group of highly fastidious, slow-growing, capnophilic, gram-negative bacteria, that normally reside in the oral cavity as commensal, but occasionally have been associated with local infections of the mouth and systemic infections such as bacterial endocarditis.

Species belonging to this group include:

- ***H****aemophilus* species: *H. aphrophilus, H. paraphrophilus* and *H. parainfluenzae*
- ***A****ggregatibacter* (formerly ***A****ctinobacillus*) *actinomycetemcomitans*
- ***C****ardiobacterium hominis*
- ***E****ikenella corrodens*
- ***K****ingella kingae*

HACEK ENDOCARDITIS

It accounts for 3% of total endocarditis cases.

- Typically has a subacute course
- Occurs in patients with preexisting valvular defects or those undergoing dental procedures
- The aortic and mitral valves are most commonly affected.

Laboratory Diagnosis

The laboratory diagnosis of HACEK endocarditis is as follows:

- They are highly fastidious, require special media
- They are capnophilic, growth is optimum in presence of 5–10% of CO_2
- Incubation up to 30 days may be required. However, the detection time may be reduced to 1 week if automated culture systems such as BACTEC are used.
- PCR can be employed which is more sensitive and rapid than culture.
- The Haemophilus species of HACEK group are described in the preceding text. Other agents of are described below.

Aggregatibacter actinomycetemcomitans

(Former name: *Actinobacillus actinomycetemcomitans).*

It is the most common member of HACEK to cause endocarditis.

- It can also be isolated from soft tissue infections and abscesses associated with *Actinomyces israelii.*
- Rarely, it causes periodontitis, brain abscess, meningitis and endophthalmitis.
- **Laboratory diagnosis:**
  - It is small non-motile gram-negative coccobacillus.
  - It grows on blood agar supplemented with 5% defibrinated horse blood.
  - Catalase and nitrate positive,
  - Ferments only glucose, galactose and maltose
  - Negative for indole, citrate, urease and decarboxylase tests.

Cardiobacterium hominis

It frequently affects the aortic valve. It is also associated with arterial embolization, immune complex glomerulonephritis or arthritis.

Laboratory diagnosis:

- It is non-motile, non-capsulated pleomorphic and gram-negative bacillus
- It grows on blood agar under 3–5% CO_2 and high humidity.
- It ferments a wide range of sugars and forms indole
- Oxidase positive, but catalase and nitrate negative.

Eikenella corrodens

It is small slender non-capsulated gram-negative bacillus. Apart from endocarditis, it also occasionally causes skin and soft tissue infections.

Laboratory diagnosis:

- It lacks flagella, but shows **twitching or jerky** motility which is due to contraction of fimbria.
- The name 'corrodens' refers to the characteristic **pitting or corroded colonies** on blood agar.
- It is oxidase-positive, catalase negative
- Positive for lysine and ornithine decarboxylase tests
- Indole, citrate and urease tests: negative.

Kingella kingae

It also causes infections of bones, joints and tendons.

- Non-motile, and gram-negative; exists as as coccobacillary and diplococcal forms
- Oxidase-positive, catalase negative

TREATMENT — HACEK endocarditis

The prognosis of HACEK endocarditis is good.

- Ceftriaxone (2 g/day) is the drug of choice for most of the HACEK organisms except *Eikenella corrodens* where ampicillin is indicated.
- Quinolones are given if the strain is a β-lactamase producer.
- Duration of treatment: Antibiotics are given for 4 weeks for native valve endocarditis and 6 weeks for prosthetic-valve endocarditis.

EXPECTED QUESTIONS

I. Write short notes on:

1. Satellitism
2. Chancroid
3. HACEK group

II. Multiple Choice Questions (MCQs):

1. **Which of the following agent of meningitis can grow on chocolate agar but not on blood agar?**
   a. *Neisseria meningitides*
   b. *Haemophilus influenzae*
   c. *Moraxella catarrhalis*
   d. *Escherichia coli*
2. ***Haemophilus influenzae* grows on all of the following media except:**
   a. Chocolate agar
   b. Fildes' agar
   c. Nutrient agar
   d. Blood agar with *S.aureus* streak line
3. **HACEK group includes all except:**
   a. *Haemophilus aphrophilus*
   b. *Haemophilus influenzae*
   c. *Eikenella corrodens*
   d. *Cardiobacterium hominis*

CHAPTER 34

Bordetella

Chapter Preview

- Bordetella pertussis
  - Virulence factors
  - Clinical manifestations
  - Laboratory diagnosis
  - Treatment and oprevention

Bordetella is highly fastidious, very small, gram-negative coccobacillus, described first by Bordet and Gengou in 1906. It is a non-fermenter, belongs to family Alcaligenaceae. It comprises of several species (Table 34.1).

- *Bordetella pertussis*: It causes whooping cough in children, a highly contagious vaccine preventable bacterial disease, characterized by paroxysmal cough ending in a high-pitched inspiratory sound described as "whoop".
- *B. parapertussis*: It causes milder form of whooping cough.
- *B. bronchiseptica*: It is a pathogen of domestic animals that causes kennel cough in dogs, atrophic rhinitis and pneumonia in pigs, and pneumonia in cats. Rarely, respiratory infections in humans have been reported.
- *B. avium*: It causes respiratory disease in turkeys.
- *B. hinzii* and *B. holmesii*: They occasionally cause bacteremia in immunocompromised people.

BORDETELLA PERTUSSIS

B. pertussis causes a violent paroxysmal productive cough in children called **whooping cough** or **100 days fever**.

Virulence Factors

B. pertussis produces a wide array of toxins and biologically active products that are important in its pathogenesis and in immunity. Most of these virulence factors are under the control of a single genetic locus that regulates their production.

Toxins

- **Tracheal cytotoxin:** It is a part of cell wall peptidoglycan, which causes damage to the cilia of respiratory epithelial cells by producing interleukin-1 and nitric oxide intracellularly.
- **Pertussis toxin:** (See the box below).
- **Adenylate cyclase toxin**: It activates cyclic AMP, which impairs the host immune function.
- **Dermonecrotic toxin**: It may contribute to the respiratory mucosal damage.
- **Endotoxin:** It has properties similar to those of other gram-negative bacterial LPS.
- **Adhesins:** They play a role in bacterial attachment. Examples include:
  - Filamentous hemagglutinin (FHA)
  - Pertactin, an outer-membrane protein
  - Fimbriae or pili or agglutinogens
  - **BrkA** (*Bordetella* resistance to killing) protein: It mediates the serum resistance and adhesion.

Pertussis Toxin (PT)

It is the most important virulence factor, and is expressed only by *B. pertussis*. *B. parapertussis* and *B. bronchiseptica* possess the genes coding for PT, but due to mutation in the promoter region of the genes, they do not express PT.

Mechanism: PT is similar to cholera toxin in its structure and is composed of A and B subunits.

- **B subunit:** It is pentameric, responsible for binding to target cells and inserting A-subunit into the cytoplasm.
- **A subunit:** It is the active subunit, which causes ADP ribosylation of G protein, which activates adenylyl cyclase, leading to ↑ concentrations of cAMP; which is responsible for producing a variety of biologic effects, such as:
  - T cell mitogenicity
  - Hemagglutination
  - Adhesion to respiratory ciliated cells
  - Inhibition of neutrophil oxidative burst, monocyte migration, histamine release from mast cells
  - Induction of leukocytosis
  - Enhancement of insulin secretion leading to hypoglycemia

TABLE 34.1: Characteristics of *Bordetella* species

Features	*B. pertussis*	*B. parapertussis*	*B. bronchiseptica*
Host	Humans	Humans, sheep	Mammals
Disease	Whooping cough	Whooping cough (mild)	Various respiratory diseases
Growth on			
Blood agar	–	+	+

Oxidase	+	–	+
Urease	–	+ (24 hours)	+ (4 hours)
Nitrate reduction	–	–	+
Toxin			
Pertussis toxin	+	–	–
Others	+	+	+

Other toxins include filamentous hemagglutinin, fimbriae, pertactin, adenylate cyclase, lipopolysaccharide, tracheal cytotoxin, ***brkA*** protein

Clinical Manifestations

The clinical course of whooping cough (or pertussis) passes through three stages following an incubation period of 7–10 days.

- **Catarrhal phase:** It lasts for 1–2 weeks, and is characterized by common cold like nonspecific symptoms, such as coryza, lacrimation, mild cough, low-grade fever and malaise. It is highly infectious stage. In this stage, both smear and cultures are likely to be positive.
- **Paroxysmal phase:** In this stage, patients are less infectious; smear and culture may become negative. It is characterized by specific symptoms, such as whooping cough and post-tussive vomiting (see the below box).
- **Convalescent stage:** It occurs following the paroxysmal stage, during which the frequency and severity of coughing gradually decreases. Antibodies may appear in serum.

Whooping Cough

Each paroxysm consists of bursts of 5–10 repetitive violent spasmodic coughs, often within a single expiration which ends with an audible sound or whoop. Whoop occurs due to rapid inspiration against a closed glottis at the end of the paroxysm (Fig. 34.1A).

- Paroxysms may be precipitated by noise, eating or physical contact. In between the paroxysms, patient may appear to be normal.
- The frequency of paroxysms varies widely, from several per hour to 5–10 per day.
- Episodes are often worse at night.
- During a spasm, there may be visible neck vein distension, bulging of eyes, tongue protrusion and cyanosis.
- Weight loss may be seen, but fever is uncommon.

Complications

Complications are more common among infants than among older children or adults.

- **Pressure effects** during the violent spasms of coughing results in subconjunctival hemorrhage, hernias, pneumothorax, rib fracture and petechiae on the face and body.
- **Pneumonia** may develop especially in old age, due to secondary infection due to encapsulated bacteria. If occurs in infants, it is usually due to *B. pertussis*.
- **Neurological complications**, such as convulsions, encephalopathy and coma may also occur.

Differential Diagnosis

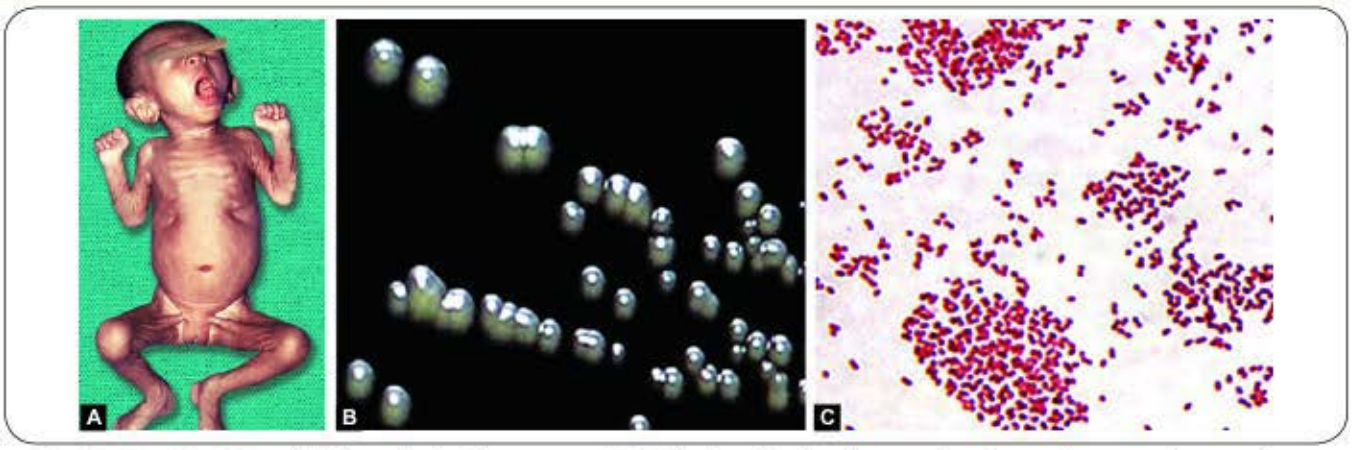
Whooping cough like symptoms may be seen with:

- *Mycoplasma pneumoniae*
- *Chlamydophila pneumoniae*
- Adenovirus
- Influenza and other respiratory viruses
- Use of angiotensin-converting enzyme (ACE) inhibitors
- Reactive airway disease
- Gastroesophageal reflux disease

Epidemiology

Whooping cough is an exclusively human disease. There is no animal reservoir.

- **Source:** Early cases (catarrhal stage) are the main source of infection. There is no carrier state.
- **Age:** Whooping cough is predominantly a disease of pre-school children below 5 years. As the maternal antibodies are not protective, infants remain the most vulnerable group, accounting for highest morbidity and mortality.
- **Shift of median age:** Pertussis has shifted from infants to older children and adolescence in countries with high vaccination coverage. This indicates that pertussis immunizations or natural infection do not provide lifelong immunity.
- **Mode of transmission:** It is via inhalation of droplets (by coughing or sneezing or even talking) or rarely through direct contact.
- **Recent outbreaks:** There are several outbreaks have been reported recently; which includes the Washington epidemic in 2012.
- **Worldwide,** the incidence of pertussis is declining. According to Provisional Pertussis Surveillance Report [Centers for Disease Control and Prevention (CDC), 2014], the number of cases reported were 48,277 and 24,231 in 2012 and 2013 respectively with highest incidence rates from Montana and Alaska.



Figs 34.1A to C: A. Female infant suffering from pertussis; **B.** Colonies of *Bordetella pertussis* on Regan-Lowe agar (mercury drops appearance); **C.** Gram-stained smear of *Bordetella pertussis* (thumb print appearance)

Source: A. Public Health Image Library, ID# 6379/Centers for Disease Control and Prevention (CDC), Atlanta; B. ATCC® 9797; C. Judith Holden, MT (ASCP), MPH, Microbiology Laboratories, Massachusetts General Hospital, Boston, MA, Partners Infectious Disease Images web site (*with permission*)

- **India:** There is marked decline of the disease after launch of the vaccine under universal immunization programme in India.
- There is no cross protection to *B. parapertussis* infection.

LABORATORY DIAGNOSIS — ***Bordetella pertussis***

- **Specimen**: Nasopharyngeal secretions, collected by alginate swabs
- **Direct smear:** Gram-negative coccobacilli and pus cells
- **Culture:**
  - Regan-Lowe medium and Bordet-Gengou agar
  - Produces mercury drops or bisected pearls colony
- **Culture smear:** Reveals small, ovoid gram-negative coccobacilli arranged in 'thumb print' appearance
- **Detection of serum antibodies:** By enzyme immunoassays
- **PCR:** Detecting IS481 and PT promoter region genes
- **Typing of *B. pertussis*:** By serotyping and genotyping

Laboratory Diagnosis

- **Specimen collection**
  - Nasopharyngeal secretions are the best specimens which may be obtained by—
    - Nasopharyngeal aspiration (best method)
    - Pernasal swab (by using a sterile swab on a flexible wire).
  - **Type of swabs used:** For culture, alginate swabs are the best followed by dacron swabs. However, for PCR, only dacron or rayon swabs are recommended.
    - Cotton swabs are not satisfactory as fatty acids present in cotton may inhibit the growth of the bacilli. However charcoal-impregnated cotton swabs (Stuart's) may be useful.
    - It is recommended to collect **six swabs,** at 1–2 days intervals to achieve maximum yield.
  - Cough plate method and post-nasal swabs used before are no longer recommended.
  - **Transport:** Specimens should be processed immediately. If delay is expected, then suitable charcoal-based medium (Amies) can be used.
- **Direct detection:** *B. pertussis* may be directly detected from nasopharyngeal secretions by direct immunofluorescence test using fluorescein labelled polyclonal or monoclonal antibodies. Because of poor sensitivity and specificity, it is not widely used.
- **Culture:** Nasopharyngeal culture remains the gold standard method of diagnosis.
  - *B. pertussis* is a strict aerobe, grows best at 35–37°C. It is fastidious, requires special complex media for primary isolation, such as—
    - Charcoal agar supplemented with 10% horse blood and cephalexin **(Regan and Lowe medium).** It is currently the medium of choice.
    - Bordet-Gengou glycerine-potato-blood agar was a traditional medium used before.
  - Colonies are greyish white, convex with a shiny surface appear after 3–5 days, described as **mercury drops** or **bisected pearls appearance** (Fig. 34.1B).
  - Culture remains positive only during the first three weeks of infection (i.e. mainly in catarrhal stage) where the symptoms are nonspecific.
  - Culture becomes negative within 5 days of start of antibiotics.
- **Culture smear:** Gram-staining of culture reveals small, ovoid coccobacilli (0.5 μm), tend to arrange in loose clumps, with clear spaces in between giving a **thumb print** appearance (Fig. 34.1C).
  - Capsules may be demonstrated in fresh cultures, but are often lost on sub-culturing.
  - Bipolar metachromatic granules may be demonstrated on staining with toluidine blue.

- **Detection of serum antibodies:** Enzyme immunoassays (EIAs) using purified antigens of *B. pertussis*, such as PT, FHA and pertactin are the methods of choice.
  - Demonstration of a rise of IgG antibodies in paired sera or detection IgA or IgM antibodies provides definite diagnosis.
  - However, antibodies are also elevated in immunized people.
- **Molecular methods:** PCR is being increasingly used in many laboratories replacing culture, because of increased sensitivity, specificity and quicker results. The most common targeted genes are IS481 and the PT promoter region genes.
- **Typing of *B. pertussis*:** It is important during outbreak investigation to find out the epidemiological link between the isolates.
  - **Serotyping:** It is based on two fimbrial antigens (type 2 and 3) and one lipooligosaccharide antigen (type 1), of *Bordetella pertussis*. Out of the four recognized serotypes (1,2,3; 1,2; 1,3; and 1) of *B. pertussis*, only the first three types (possessing fimbriae) infect man.
  - **Genotyping:** It can be carried out by gene sequencing, and pulsed-field gel electrophoresis (PFGE).
- **Others:** Lymphocytosis is common among young children but not among adolescents.

TREATMENT — Pertussis

As pertussis is mainly toxin mediated, antibiotics are less useful once the infection is established. However, they play a vital role to eliminate the bacteria from nasopharynx.

- Macrolides are the drugs of choice (erythromycin for 7–14 days).
- Cotrimoxazole is recommended as an alternative in macrolide resistance.

Isolation in a quiet environment may inhibit the stimulation of paroxysms. Cough suppressants are not much effective.

Prevention

Chemoprophylaxis

Erythromycin is widely recommended as chemoprophylaxis for household contacts of pertussis cases.

Vaccine

Whole-cell Pertussis Vaccines

It is prepared by heating followed by chemical inactivation and purification of whole *B. pertussis* bacilli.

- Efficacy is good, average being 85%.
- **DPT vaccine:** In India and many other countries, whole cell (WC) pertussis vaccine is given under national immunization programme, along with diphtheria toxoid and tetanus toxoid. Three doses of DPT are given at 6, 10 and 14 weeks, followed by two boosters at 1½ years and 5 years. *Pertussis* component acts as an adjuvant and increases immunogenicity of DT and TT.
- **Adverse effects:** WC vaccine is associated with the following adverse effects, such as:
  - Common: Fever, injection-site pain, erythema, swelling, and irritability.
  - Uncommon: *Bordetella pertussis* is encephalitogenic. It is associated with neurological complications (encephalitis, prolonged convulsion) and **hypotonic hyporesponsive syndrome**. The estimated risk is 1:1,70,000 doses administered.
- **Contraindication:** Because of the adverse effects, the WC vaccine is contraindicated in—
  - Children more than 5–6 years age.
  - Any associated progressive neurological conditions.
  - Children with strong family history of epilepsy.
  - Hypersensitivity to previous dose.

Acellular Pertussis Vaccine

- It is composed of pertussis toxoid and 2 or more other bacterial components such as FHA, pertactin or fimbriae.
- Though the efficacy is same as WC vaccine, it is associated with fewer side effects as compared with the latter and can be safely given after 5–6 years.

EXPECTED QUESTIONS

I. Write short notes on:

1. Virulence factors of *Bordetella pertussis*
2. Laboratory diagnosis of pertussis
3. Vaccination against pertussis

II. Multiple Choice Questions (MCQs):

1. Mercury drop appearance colony of *B. pertussis* is seen on which of the following culture media?
a. Blood agar b. Chocolate agar
c. Regan-Lowe agar d. Nutrient agar

2. Pertussis toxin is produced by:
a. *B. pertussis* b. *B. parapertussis*
c. *B. avium* d. *B. bronchiseptica*

3. Which is the highly infective stage in whooping cough?
a. Catarrhal stage b. Paroxysmal stage
c. Convalescent stage d. All of the above

Answers

CHAPTER 35

Brucella

Chapter Preview

- Introduction and classification
- Pathogenesis
- Clinical manifestations
- Epidemiology
- Laboratory diagnosis
- Treatment and prevention

INTRODUCTION

Brucella is an obligate aerobic, fastidious, nonsporing, nonmotile, noncapsulated small gram-negative coccobacillus, responsible for a highly contagious febrile illness called **brucellosis**.

- Brucellosis (also called **undulant fever**) is primarily a zoonotic disease affecting various domestic animals, such as sheep, goat or cattle.
- Human infection is usually associated with occupational or domestic exposure to infected animals or their products.

History

- *Brucella* was named after British army physician Sir David Bruce (1886), who isolated the first recognized species, *Brucella melitensis* (*melita* is Roman name for Malta) from Malta Island (Europe); hence the disease was called Malta fever.
- Danish physician Bernhard Bang (1897) isolated *Brucella abortus* from cattle (Bang's disease).
- *Brucella suis* was isolated from aborted swine in 1914 by Jacob Traum from USA.

Nomen System of Classification

Brucella belongs to the family Brucellaceae.

- DNA hybridization studies reveal that the members of the genus *Brucella* are very closely related and probably represent variants of a single species.
- However, for the sake of convenience, these have been classified into **nomen species**, based on various properties, such as:
  - Preference of animal host
  - CO_2 requirement
  - H_2S production
  - Genetic composition
  - Bacteriophage susceptibility
  - Tolerance to bacteriostatic dyes
  - Agglutination with monospecific antisera
- **Nomen species:** Currently there are six nomen species identified, among which few are further classified into several biovars (Table 35.1).
  1. *B. melitensis:* It has 3 biovars. It is usually pathogenic to sheep, goat and camel. Man is also a susceptible host.
  2. *B. abortus:* It has 9 biovars and infection is acquired from cattle and buffalo.
  3. *B. suis:* It has 5 biovars, and they infect most often pigs, but some biovars may infect reindeers and rodents.
  4. *B. canis:* It causes abortion in dogs. Occasional cases of human infection have been reported.
  5. *B. ovis:* It causes reproductive disease in sheep.
  6. *B. neotomae:* It infects desert rodents.

Antigenic Structure

Brucellae have two major types of lipopolysaccharide (LPS) antigens designated as **M** and **A**.

- They are present in varying proportion in the three major species of *Brucella*; however, one of them is predominant in each species.
  - In most of the biovars of *B. melitensis,* M antigen is predominant.
  - In most of the *B. abortus* biovars, A antigen is predominant.
  - *B. suis* biovars contain either M or A antigens.
- The virulent colonies on primary isolation are smooth and possess the LPS antigen. However, on repeat subcultures, strains may lose LPS and becomes rough strains which may not agglutinate with anti-M or anti-A antisera.
- *B. canis* produces rough (R) strains even on primary isolation, which do not agglutinate with antisera to M or A antigen but agglutinate with antiserum prepared against R strains.

TABLE 35.1: Differentiating characters of *Brucella* species

Nomen species	Biovars	CO_2 requirement	H_2S production	Urease	Growth on media containing dyes[a]		Lysis by bacteriophage at RTD			Agglutination by antiserum[b]		Common animal reservoir

+, Positive; –, negative; (+), most strains positive; (–), most strains negative, [a]Dye concentration, 20 µg/mL.

[b]A, monospecific antisera to *B.abortus* A antigen, M, monospecific antisera to *B. melitensis* M antigen; [c]*B.canis* can agglutinate with antiserum prepared against rough (R) strains; L, lysis; NL, no lysis at routine test dilution (RTD) by *Brucella* phages

PATHOGENESIS

B. melitensis is the most pathogenic species, followed by *B. abortus* and *B. suis*. Human infection with other species is extremely rare.

Transmission

Brucellosis is usually transmitted from infected animals to man. There is no evidence of man-to-man transmission. The various modes of transmission are:

- **Direct contact:** The most common route is direct contact with the infected animal tissue, blood, urine, vaginal discharge or placenta with abraded skin or mucosa of men, who are involved in animal handling.
- **Food-borne:** By ingestion of raw milk or dairy products from infected animals or rarely vegetables or water contaminated with animal excreta.
- **Air-borne:** By inhalation of dust or aerosols in the infected cowshed or slaughter houses.

Spread

From the initial site of infection, the organisms spread via lymphatic vessels → infect the local lymph glands → organisms spillover to bloodstream results in bacteremia → disseminate throughout to involve various organs.

Organs Involved

Brucellae are facultative intracellular pathogens, primarily infecting organs of the **reticuloendothelial system**, such as lymph nodes, spleen, liver and bone marrow which are rich in mononuclear phagocytic cells (macrophages and monocytes).

- They also have a special predilection for placenta as their growth is enhanced in the presence of erythritol present in placenta.
- Musculoskeletal tissues and genitourinary systems are also frequently targeted.

- **Local tissue response:** Initially, an acute neutrophilic infiltration occurs. Later on, it is replaced by chronic inflammatory cells leading to granuloma formation with or without necrosis and caseation.

Intracellular Survival and Virulence Factors

The **cell-wall LPS** appears to be the major virulence factor. It has a distinct O-chain and core-lipid composition. Though the endotoxin activity is relatively low, it plays a key role in:

- Providing resistance to phagocytosis and serum complement-mediated killing of bacteria.
- Suppressing phagosome-lysosome fusion.
- Diverting the internalized bacteria into vacuoles located in endoplasmic reticulum, where intracellular replication takes place.
- Development of pyrogenicity.

Other virulence factors are as follows:

- Type IV secretion system (VirB): It is a type of secretory system present in brucellae, that regulates intracellular survival in phagosomes and trafficking.
- Cu-Zn superoxide dismutase: It is expressed by *B. abortus* that inhibits reactive oxygen radicals.
- Nucleotide-like substances have been recovered from *B. abortus* that inhibit phagolysosome fusion and reactive oxygen radicals produced from neutrophils.

Host's Immune Response

Cell-mediated immunity (CMI) is the key to control the infection.

- Activation of T helper -1(T_H1) cells provides protective immunity by production of interferon γ, which leads to macrophage activation and killing of intracellular *Brucella*.
- On the other hand, T_H2 activation leads to secretion of IL-4, IL-6 and IL-10, that downregulates the protective T_H1 immune response and stimulates humoral immunity.
- However, antibodies play only a minor role as they are active only in extracellular milieu. Once the brucellae are internalized, antibodies are ineffective.

CLINICAL MANIFESTATIONS

The incubation period varies from 1 week to several months and the onset is either abrupt or more often insidious.

- **Classic triad:** Though the manifestations vary, the classic triad of fever with profuse night sweats, arthralgia/arthritis and hepatosplenomegaly are present in most patients.
- **Typhoid-like illness:** Overall brucellosis resembles typhoid-like illness except that it is less acute, less severe with undulating pattern of fever and more musculoskeletal symptoms.
- **Undulating fever:** Fever has a typical remittent course, i.e. in between febrile periods (which last for weeks), there will be afebrile periods. It is also called Malta fever or Mediterranean fever.
- **Musculoskeletal symptoms** are present in about one-half of all patients, which may mimic skeletal tuberculosis.
  - Vertebral osteomyelitis involves lumbar and low thoracic vertebrae commonly.
  - Septic arthritis: Most commonly affected joints are knee, hip, sacroiliac and shoulder joints.
- **Other nonspecific symptoms:** These include abdominal pain, headache, diarrhea, rash, weakness/fatigue, weight loss, vomiting, cough, pharyngitis, and refusal to eat (children).
- **CNS:** Depression and lethargy with meningitis or lymphocytic meningoencephalitis are the most common neurological manifestations.
- **CVS:** Endocarditis may occur rarely, affecting the aortic valve.
- **Genitourinary manifestations:** These include acute epididymo-orchitis, prostatitis, salpingitis and pyelonephritis.

All the nomen species produce similar manifestations; but exhibit slight variations between each other, e.g.

- *B. melitensis* tends to produce more acute and aggressive presentation
- *B. suis* produces focal abscess
- *B. abortus* tends to be more insidious and chronic
- *B. canis* produces acute gastrointestinal symptoms

EPIDEMIOLOGY

Brucellosis is a worldwide zoonotic disease.

The occurrence in humans is closely related to their prevalence in various domestic animals.

- **Endemic area:** Human brucellosis is endemic in areas where animals are raised in large numbers, such as countries of Mediterranean zone, Eastern Europe, Central Asia, Mexico and South America.
- The disease is rare in most European countries, Australia and North America.
- **Prevalence:** The true prevalence of human brucellosis is difficult to estimate. Many cases are under-reported either because they are inapparent or due to difficulty in diagnosis.
- **Sources of infection** are:
  - Infected animals excreting the organisms in urine, milk, placenta or vaginal discharge.

- Contaminated animal food products, such as dairy products, especially soft cheeses, milk, icecream and rarely raw meats and bone marrows.

- **People at higher risk** are farmers, shepherds, goatherds, butchers and abattoir workers in endemic areas (occupationally exposed to infection).

Resistance

Brucellae are sensitive to sunlight, ionizing radiation, and moderate heat; they are killed by boiling and pasteurization.

- They are resistant to freezing and drying which renders brucellae stable in aerosol form, facilitating airborne transmission.
- The organisms can survive for up to 2 months in soft cheeses; 6 weeks in dry soil; and 6 months in damp soil or liquid manure kept under cool dark conditions.
- Brucellae are easily killed by common disinfectants and their efficacy decreases at low temperatures or in the presence of heavy organic matter.

LABORATORY DIAGNOSIS — *Brucella melitensis*

- **Specimens:** Blood, bone marrow, etc.
- **Culture medium:**
  - Castaneda's biphasic media (BHI broth/agar)
  - Automated techniques such as BACTEC
- **Culture smear and motility testing:** Reveals non motile gram-negative coccobacilli
- **Biochemical tests (see text):** Catalase, oxidase and urease test positive
- **Nomen species identification (see text)**
- **Serological tests (antibody detection)**
  - Standard agglutination test (SAT)- detects IgM
  - Tests to detect IgG antibody -2ME test, CFT, ELISA
- **Molecular method:** PCR detecting *rrs-rrl* gene, *Omp2* gene and IS711 insertion sequence
- Brucellin skin test
- Guinea pig inoculation
- **Diagnosis of brucellosis in animals**
  - Isolation of brucellae from milk and dairy products
  - Antibody detection in milk: By Milk ring test and Rose Bengal card test, whey agglutination test.

LABORATORY DIAGNOSIS

Culture and Identification

Sample

Brucellae are recovered from blood, bone marrow, CSF, joint fluid or other tissues.

- Blood should be collected during the febrile period before starting of antibiotics. Multiple blood cultures (5–10 mL, 2–3 times a day) over 3 consecutive days yield better result.
- Bone marrow culture remains positive even after starting antibiotics and gives a higher yield than blood culture.

Cultural Conditions

Brucellae are highly fastidious and the growth is enhanced by the addition of blood or serum.

- They are obligate aerobes, but growth is promoted in the presence of 5–10% CO_2.
- Primary isolation requires prolonged (several weeks) incubation at 37°C.

Cultural Media

- Blood culture bottles are the recommended media. Biphasic media (Castaneda's) are superior to monophasic media (Fig. 35.1A).
  - Brain heart infusion (BHI) broth/agar or serum dextrose broth/agar are the appropriate media used.
  - Repeat subcultures are made onto blood agar and chocolate agar.
  - Biphasic media have less contamination rate as the colonies can be obtained on the solid phase just by tilting the bottles so that the broth runs over the agar slope, thereby avoiding contamination during subculture.
  - Blood culture bottles should be incubated at least for 2-4 weeks or more.
- Automated techniques, such as BACTEC and BacT/Alert systems can be used which take less time for isolation (7–10 days) and have better recovery rates (Fig. 35.1B).

Culture Smear and Motility Testing

On blood agar and chocolate agar, colonies are small, smooth, transparent, low convex with entire edge and non-hemolytic.

- Gram-staining of colonies reveals non-capsulated, non-sporing, small, gram-negative coccobacilli (Fig. 35.1C).
- Brucellae are nonmotile.

Biochemical Tests

Brucellae show the following biochemical properties:

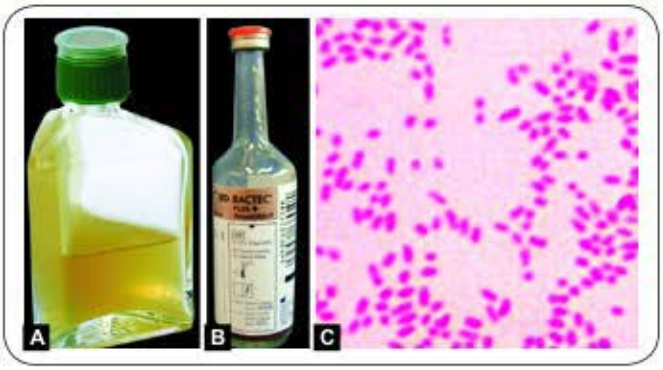
- Do not ferment carbohydrates
- Catalase positive
- Oxidase positive (except some strains of *B. abortus*, *B. neotomae* and *B. ovis*)
- Urease test is variable but often rapidly positive, especially with strains of *B. suis* and *B. canis*.
- Nitrate is reduced to nitrite (except *B. ovis*)
- Citrate, indole, MR and VP tests are negative.

Nomen Species Identification

The nomen species are identified based on the following tests:

- Preference of animal host
- CO_2 requirement
- H_2S production

Contd...



Figs 35.1A to C: A. Blood cuture bottles (Biphasic medium); **B.** BACTEC; **C.** Gram-stained smear of *Brucella* species showing small gram-negative coccobacilli

Source: C. Public Health Image Library, ID# /15243, Dr. W.A. Clark/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Contd...

- Tolerance to bacteriostatic dyes, such as basic fuchsin and thionine
- Agglutination with monospecific antisera: Predominant A or M antigen of LPS in a strain can be determined in slide or tube agglutination tests by testing a killed suspension of organisms against absorbed monospecific antisera to A or M strain.
- Lysis by bacteriophages: A standard reference strain of Tbilisi phage is used for phage typing.

Serological Tests (Antibody Detection)

As isolation is difficult, serological tests are of paramount importance in diagnosis of brucellosis. Several tests have been developed, such as standard agglutination test, complement fixation and ELISA.

Standard Agglutination Test (SAT)

It remains the gold standard test against which other serological tests are compared.

- **Procedure:** It is a tube agglutination test. The equal volumes of serial dilutions of patient's sera are mixed with the killed smooth suspension of a standard strain of *B. abortus* and incubated at 37°C for 48 hours.
- **Result:** Significant titer is:
  - Titer of more than 1:160 is considered as significant in nonendemic areas.
  - In an endemic area, demonstration of rising titer by repeating the test after 2–4 weeks is more reliable.
- **Interpretation:**
  - SAT detects antibodies against antigens of smooth LPS. Use of *B. abortus* can detect antibodies against *B. melitensis, B. abortus* and *B. suis* but not *B. canis* (as it lacks smooth LPS).
  - In acute infection, IgM antibodies appear early and are followed by IgG and IgA antibodies. The SAT measures the total quantity of agglutinating antibodies but does not differentiate between immunoglobulin isotypes.
  - As the disease progresses, IgM levels decline, and the avidity and subclass distribution of IgG and IgA change. Thus, SAT may become negative.
- **False-negative SAT** may occur due to:
  - Prozone phenomenon (due to excess of antibodies in patient's sera): This may be obviated by performing the test in serially diluted patient's sera.
  - Presence of 'blocking' or nonagglutinating IgG or IgA antibodies: This can be removed by:
    - Prior heating of serum at 55°C for 30 min
    - Using 4% saline to dilute patient's sera
    - Detecting 'incomplete' antibodies by Coombs antiglobulin test (most reliable)
- **False-positive SAT** may occur due to antigenic cross-reactions with some other gram-negative bacteria having similar O chains, such as *Escherichia coli* O157, *Francisella tularensis, Salmonella enterica* group N, *Stenotrophomonas maltophilia* and *Vibrio cholerae*.

Serological Tests to Detect IgG Antibody

- **2-mercaptoethanol (2ME) agglutination test:** Here, the serum is treated with disulfide reducing agents such as 2-ME so that it destroys the agglutinability of IgM, but does not alter IgG. SAT performed in 2ME treated serum, would detect only IgG.
- Complement fixation test (CFT) detects both IgM and IgG antibodies.
- **ELISA** detecting antibodies to LPS antigen is more sensitive and can detect IgM and IgG antibodies separately.

Molecular Method

PCR using primers for *rrs-rrl* gene, *Omp2* gene (outer-membrane protein), the insertion sequence *IS711* are available. PCR is rapid, sensitive and specific and can also differentiate between the species and biovars.

Brucellin Skin Test

It is an intradermal test similar to tuberculin test. It is no longer in use now.

Guinea Pig Inoculation

The specimen is inoculated into the thigh of the guinea pigs (the most susceptible laboratory animal to brucellae); lymph node or spleen aspirates are cultured after the death of the animals.

Diagnosis of Brucellosis in Animals

Brucellosis is diagnosed in animals by various methods such as:

- **Isolation from milk and dairy products:** Culture of the overnight cream of the cow's milk has shown better isolation rate.
- **Antibody detection in milk:**
  - **Milk ring test:** Pooled milk is mixed with a drop of the stained *Brucella* antigen in a narrow test tube and incubated at 70°C for 40–50 minutes.
    - If antibodies are present in the milk, bacilli are agglutinated and rise to form a blue ring at the top, leaving the milk unstained.
    - If antibodies are absent, no coloured ring is formed and milk remains uniformly blue.
  - **Rose Bengal card test** and the **whey agglutination test** are the other useful methods.

TREATMENT **Brucellosis**

Various regimens are recommended for the treatment of brucellosis.

- **Gold-standard regimen** in adults: Streptomycin for 14–21 days plus doxycycline for 6 weeks.
- **WHO regimen** in adults: Rifampin for 6 weeks plus doxycycline for 6 weeks.
- Relapse or treatment failure occurs in 5–10% of cases.
- **For CNS involvement:** Ceftriaxone is added to the regimen and treatment is prolonged for 3–6 months.

Prevention

Prevention in Animals

The most rational approach to control human brucellosis is to control and eradicate infection from its animal reservoirs.

- **Test and slaughter:** Active case finding is done in animals by skin test or CFT. Infected animals are slaughtered.
- **Vaccine:** Live attenuated vaccine using *B. abortus* 19 strain for cattle and *B. melitensis* rev-1 strain for sheep and goat are available.

Prevention in Humans

General precautions such as:

- Use of pasteurized milk or properly cooked food.
- Use of protective measures to prevent direct contact with animals.

Vaccine:

Live attenuated *B. abortus* 19–BA is available for human use but provides short term protection and had shown high reactogenicity.

EXPECTED QUESTIONS

I. Write short notes on:

1. Pathogenesis of brucellosis
2. Laboratory diagnosis of brucellosis
3. Castaneda's method of blood culture

II. Multiple Choice Questions (MCQs):

1. *Brucella melitensis* is commonly found in which animal?
   a. Pig
   b. Dog
   c. Cattle
   d. Goat

2. Malta fever is also called as:
   a. Undulant fever
   b. Relapsing fever
   c. Hemorrhagic fever
   d. Rat bite fever

3. All of the following serological tests would be helpful in the diagnosis of chronic brucellosis except:
   a. Standard agglutination test
   b. Mercaptoethanol test
   c. Complement fixation test
   d. ELISA detecting IgG

Answers

1. d **2.** a **3.** a

CHAPTER 36

Miscellaneous Gram-negative Bacilli

Chapter Preview

- Campylobacter species
- Helicobacter species
- Legionella species
- Pasteurella species
- Francisella species
- Chromobacterium species
- Capnocytophaga species
- Agent causing donovanosis
- Agents causing rat bite fever
- Agents causing bacterial vaginosis

CAMPYLOBACTER

Campylobacter species cause both diarrheal and systemic diseases. They are motile, nonsporing, microaerophilic, curved gram-negative rods.

Human pathogens fall into two major groups:

1. Primarily diarrheal disease: It is caused by *C. jejuni* (accounting for 80–90% of total cases), and others such as *C. coli*, *C. upsaliensis*, *C. lari*, *C. hyointestinalis*, *C. fetus*.
2. Extraintestinal infection: Caused by *C. fetus*.

Epidemiology

- **Source:** *Campylobacter* species are zoonotic, found in the intestine of many animals (poultry, cattle, sheep and swine) and household pets (including birds, dogs and cats). However, animals are asymptomatic.
- **Mode of transmission:** *Campylobacter* is transmitted by the following routes.
  - By raw or undercooked food products: ingestion of contaminated poultry (most common), raw (unpasteurized) milk or untreated water.
  - Through direct contact with the infected household pets.
  - Travel to developing countries (can cause traveller's diarrhea).
  - Oral-anal sexual contact.
- **Age:** Persons of all ages are affected; however:
  - *C. jejuni* infection is common among children.
  - In contrast, *C. fetus* infection is the highest in extremes of age.
- **Developing versus developed countries:**
  - In the developing countries, *C. jejuni* infections are hyperendemic, mostly present as asymptomatic infection except children less than 2 years (usually symptomatic).
  - In developed countries, *Campylobacter* is the leading bacterial cause of diarrhoeal disease, more common than *Shigella* and *Salmonella*.
- **Seasonality:** Incidence peaks during summer and early autumn.

Pathogenesis

Pathogenesis of *C. jejuni* is due to expression of the following virulence factors:

- Motility of the strain (possesses single polar flagellum and exhibits darting motility)
- Capacity to adhere to host tissues
- The following toxins play a minor role:
  - Enterotoxin (Heat-labile, similar to cholera toxin)
  - Cytotoxins (cytolethal distending toxin, or CDT)
- Proteinaceous capsule-like structure (S-layer) expressed by *C. fetus*: It prevents the bacilli from complement-mediated killing and opsonisation and may contribute to the chronicity and high rate of recurrence of *C. fetus* infections in immunocompromised hosts.

Clinical Manifestations

The clinical manifestations seen in campylobacteriosis are as follows.

- **Intestinal infection:** It is characterized by inflammatory diarrhea, abdominal pain and fever. Degree of diarrhea varies from several loose stools to grossly bloody stools. It is self-limiting; however, relapse is seen in 5–10% of untreated cases.
- **Extraintestinal infection:** It is mainly due to *C. fetus* developing mostly in immunocompromised hosts and at the extremes of age. Common manifestations include bacteremia, sepsis, meningitis, vascular infections (endocarditis, aneurysm, and thrombophlebitis).

- **In persons with the HLA-B27 phenotype:** Reactive arthritis and other rheumatologic manifestations may develop several weeks after infection with *Campylobacter*.
- *Campylobacter* triggers the pathogenesis of various other diseases such as:
  - Guillain–Barré syndrome (mainly by *C. jejuni* serotype O19).
  - Alpha chain disease, a form of lymphoma that originates in small intestinal mucosa-associated lymphoid tissue.

Laboratory Diagnosis

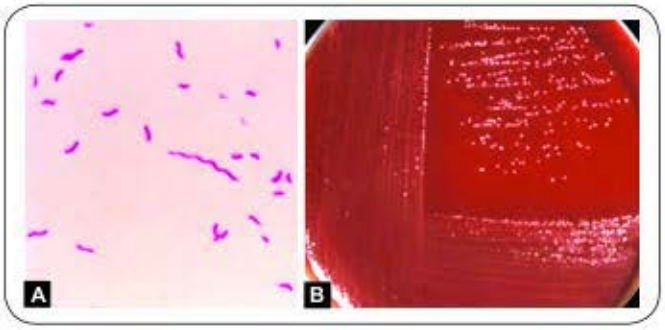
Direct Microscopy

- Gram-staining of smear of feces may show curved gram-negative bacilli, 0.2–0.5 × 1.5–5 µm, appearing comma (resembling *Vibrio*), S-shaped or spiral (*gull wing*-shaped) (Fig. 36.1A).
- Dark ground microscopy demonstrates the darting motility of the bacilli.

Culture

The culture media for *Campylobacter* are as follows:

- **Transport medium:** If delay is expected, transport medium such as Cary-Blair medium can be used. It survives for 1–2 weeks at 4°C.
- **Selective media:** Feces or rectal swabs are plated onto selective media such as:
  - Skirrow's selective medium (Fig. 36.1B)
  - Butzler's selective medium
  - Campy BAP selective media (contains lysed blood agar, vancomycin, polymyxin B, trimethoprim, cephalothin and amphotericin B).
- **Culture conditions:** Inoculated plates are incubated at:
  - Microaerophilic condition (5% O_2, 10% CO_2 and 85% nitrogen).



Figs 36.1A and B: *Campylobacter*—**A.** Gram-negative spiral rods; **B.** Growth on Skirrow's media

Source: Public Health Image Library: A. ID#: 6657; B. D#: 3918/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Growth at 42°C:** Thermophilic *Campylobacter* species (*C. jejuni, C. coli and C. lari*) can be differentiated from *C. fetus*, which is nonthermophilic.
- After 2–5 days of incubation, characteristic **effuse droplet-like colonies** are produced which can be further subjected to biochemical tests for species identification.

Biochemical Identification

Campylobacters are oxidase positive, catalase positive, nitrate reducers and do not ferment sugars.

- *C. jejuni* has two subspecies: *jejuni* and *doylei*. The subspecies *jejuni* can be differentiated from the latter by:
  - Nitrate positive
  - Hippurate hydrolysis positive
  - Growth at 42°C
- *C. upsaliensis* is catalase negative
- *C. hyointestinalis* is H_2S positive

TREATMENT — Campylobacteriosis

Fluid and electrolyte replacement is the mainstay of treatment. Antibiotics can be given, such as:

- **Diarrheal disease:** Oral macrolides are the drug of choice (erythromycin or azithromycin). Ciprofloxacin can be used as an alternative drug for adults.
- **Systemic infection:** Parenteral gentamicin (or imipenem or chloramphenicol) should be started empirically, but susceptibility testing should then be performed.

HELICOBACTER

Helicobacter pylori is curved gram-negative rod that colonizes stomach and is associated with peptic ulcer disease and gastric carcinoma. Two other *Helicobacter* species; *H. cinaedi* and *H. fennelliae* are intestinal rather than gastric organisms and cause diarrheal disease.

Pathogenesis

Colonization of the Gastric Mucosa

H. pylori colonizes the stomach of 50% of the world's human population (30% in developed countries to nearly 80% in developing countries). The colonization is favored by the following factors:

- **Motility:** *H. pylori* is highly motile (conferred by 4 to 8 unipolar flagella), which allows it to remain in the viscous environment of the mucus layer overlying the gastric mucosa.
- **Acid-resistance:** It may be due to:
  - **Urease enzyme:** It produces abundant urease that catalyzes urea hydrolysis to produce ammonia which in turn buffers the gastric acid.

- **Amidase and arginase:** May contribute to the production of ammonia.
- **Ure-I** protein: It regulates the passage of urea across the cell membrane into cytoplasm.

- **Adhesins:** Though most *H. pylori* remain within the mucus layer, a few (~2%) may bind to mucosal epithelium by expressing adhesion molecules such as:
  - Blood group antigen-binding adhesion: Binds to Lewis blood group antigen
  - Adherence-associated lipoprotein
- **Resistance to oxidative stress:** *H. pylori* produces many detoxifying enzymes that protect against the effects of oxygen-derived free radicals generated from the bacterium's own metabolism and the inflammatory defences of the host.

Induces Pathological Changes

- **Vacuolating cytotoxin (VacA):** *H. pylori* secretes VacA that induces the formation of vacuoles in the cytoplasm of epithelial cells.
- **Cytotoxin-associated Gene A (CagA):** It is a pathogenicity island that encodes a type IV secretion system. It is a syringe-like structure that gets translocated on host cell surface which helps to inject effector molecules into the host cell. This allows the bacterium to modulate certain aspects of the host cell's metabolism including:
  - Cytoskeletal rearrangements
  - Host-cell morphological changes
  - Expression of proto-oncogenes
  - Release of proinflammatory cytokines from gastric epithelial cells
- **Molecular mimicry:** Lipopolysaccharide of *H. pylori* (glycoprotein moiety) is identical to the Lewis blood group antigen expressed on gastric parietal cells which may result in:
  - Immune tolerance by downregulating T cells.
  - Induction of autoantibodies that cross-react with mucosal epitopes and contribute to the development of chronic active gastritis.
- **Alteration in gastric mucus:** LPS also inhibits glycosylation and sulfation of gastric mucus, which may impede its protective function and increase the vulnerability of the epithelial surface to gastric acidity.
- **Host factors:** People with polymorphisms in cytokine genes (e.g. interleukin 1) or genes coding Toll-like receptors are at increased risk of gastric adenocarcinoma.
- **Environmental risk factors**
  - Smoking increases the risks of ulcers and cancer in *H. pylori*-colonized individuals.
  - Diets high in salt and preserved foods increase cancer risk, whereas diets high in antioxidants and vitamin C are protective.

Clinical Manifestations

- **Acute gastritis** (Antrum is the most common site involved, cardiac end is not involved).
  - Antral gastritis: it predisposes to duodenal ulcers.
  - Pangastritis: it predisposes to adenocarcinoma of stomach.
- **Peptic ulcer disease:** 80% of duodenal ulcers and 60% of gastric ulcers are due to *H. pylori*.
  - Mechanism of duodenal ulcer: *H. pylori*-induced inflammation inhibits somatostatin producing D cells → ↑ gastrin release → ↑ meal-stimulated acid secretion → induces duodenal ulcer and gastric metaplasia of duodenal mucosa.
  - Mechanism of gastric ulcer: Though not clear, however, it is believed that there is hypochlorhydria despite increased gastrin release.
  - Epigastric pain with burning sensation: It is the most common presentation.
    - In duodenal ulcer: Pain occurs usually following a meal.
    - In gastric ulcer: Pain occurs in empty stomach.
- Chronic atrophic gastritis
- Autoimmune gastritis
- Pernicious anemia
- Adenocarcinoma of stomach
- Non-Hodgkin's gastric lymphoma

Protective Role for H. pylori

Colonization of *H. pylori* has an inverse relation with the occurrence of:

- Gastroesophageal reflux disease (GERD),
- Barrett's esophagus
- Adenocarcinoma of esophagus
- Allergic disorders including asthma

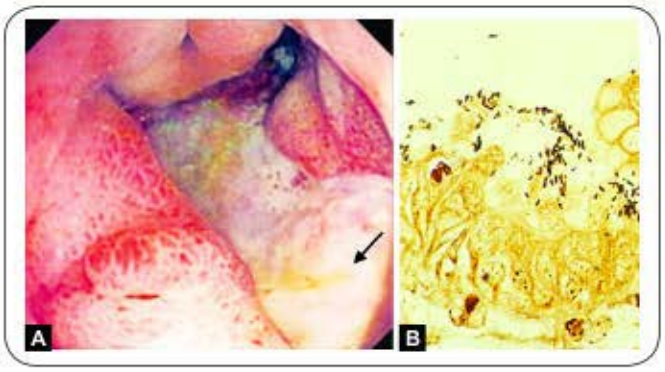
Laboratory Diagnosis

Diagnosis of *H. pylori* infection may be established by invasive and noninvasive methods.

Invasive Test

Endoscopy-guided multiple biopsies can be taken from gastric mucosa (antrum and corpus) (Fig. 36.2A) and are subjected to:

- **Histopathology** with Warthin Starry silver staining (Fig. 36.2B). Sensitivity can be improved by the use of immunostaining with anti-*H. pylori* antibody.



Figs 36.2A and B: A. Endoscopy shows duodenal ulcer due to *H. pylori*; (arrow showing) **B.** *H. pylori* (black curved rods) colonized on the gastric mucosa, Warthin-Starry staining

Source: A. Wikipedia; B. Yutaka Tsutsumi, MD, Professor, Department of Pathology, Fujita Health University School of Medicine (*with permission*)

- **Microbiological methods**
  - **Gram-staining:** Curved gram-negative bacilli with seagull-shaped morphology.
  - **Culture media** for *H. pylori*:
    - Media for *Campylobacter* can be used, such as Skirrow's media.
    - Chocolate agar can be used.
    - Plates are incubated at 37°C under microaerophilic condition (5% O_2, 10% CO_2 and 85% nitrogen).
    - Culture is the most specific test; however, it is not sensitive.
  - **Biochemical tests:** Oxidase, catalase and urease tests are positive.
- **Biopsy urease test** (also called **rapid urease test**): It detects the presence of urease activity in gastric biopsies by using a broth that contains urea and a pH indicator. It is rapid, sensitive and cheap.

Noninvasive Tests

- **Urea breath test:** Patient drinks a solution of urea labeled with the nonradioactive ^{13}C and then blows into a tube. If *H. pylori* urease is present, the urea is hydrolyzed and labeled CO_2 is detected in breath samples by mass spectroscopy. Urea breath test is very popular nowadays as it is noninvasive and is:
  - Most consistent and accurate test
  - Most sensitive, quick and simple
  - Used for monitoring of treatment (becomes negative after improvement)
- **Stool antigen (coproantigen) assay:**
  - Used for monitoring of treatment
  - Useful for screening of children.
- **Antibody(IgG) detection** by ELISA: It is used for:
  - Screening before endoscopy
  - Seroepidemiological study

TREATMENT ***H. pylori* infection**

Treatment for *H. pylori* infection

Treatment in *H. pylori* infections is indicated for: (i) duodenal or gastric ulceration; (ii) low-grade gastric B-cell lymphoma.

- However, treatment is not recommended for asymptomatic colonizers or primary prophylaxis for gastric cancer because of risk of adverse side effects and development of antibiotic resistance.
- Usually multidrug regimens are used. Monotherapy is not useful because of inadequate antibiotic delivery to the colonization niche.
- Success of treatment depends on: (i) Patient's close compliance with the regimen; and (ii) Use of susceptible antibiotics.
- Treatment guideline recommended is as follows:

Treatment regimen for *H. pylori* infections:

1st line triple drug therapy (OCM or OCA regimen):

Omeprazole + Clarithromycin + Metronidazole or Amoxicillin given for 7–14 days.

↓

Urea breath test is done after 1 month's gap

↓

If 1st line regimen fails (Urea breath test is +ve)

↓

2nd line quadruple drug therapy (OBMT regimen):

Omeprazole + Bismuth subsalicylate + Metronidazole + Tetracycline given for 14 days

↓

If 2nd line quadruple drug therapy fails, then:

Culture of endoscopy-guided biopsy is done and treatment is given based on antimicrobial susceptibility test

LEGIONELLA

Legionellae are fastidious, pleomorphic gram-negative, short rods, associated with two clinical syndromes:

- Pontiac fever is an acute, milder flu like self-limited illness
- Legionnaires' disease—severe interstitial pneumonia.

History

Legionella was first recognized in 1976 when an outbreak of pneumonia took place at a Philadelphia hotel during an American Legion convention.

Classification

The family Legionellaceae comprises more than 50 species (with >70 serogroups), out of which 19 species have been associated with human infections.

- *L. pneumophila* is the most important species, associated with 80–90% of human infections. It consists of 15 serogroups. Majority of cases are associated with **serogroup 1** followed by 4 and 6.
- Other species are rarely associated with human infection particularly in immunocompromised state, such as *L. micdadei* (Pittsburgh pneumonia agent), *L. bozemanii*, *L. dumoffii*, and *L. longbeachae*.

Epidemiology

- **Reservoir:** *Legionella* inhabits on aquatic bodies which could be either:
  - Natural water sources, such as rivers, streams or even inside amebae
  - Artificial aquatic sources, such as air conditioners, water coolers
  - *L. longbeachae* has been isolated from natural soil and commercial potting soil.
  - There is no animal reservoir
  - There is no carrier stage
- **Transmission:** Multiple routes have been proposed.
  - Aspiration (predominant mode): It occurs either via oropharyngeal colonization or directly via drinking of contaminated water.
  - Aerosols from contaminated air conditioners, nebulizers, and humidifiers.
  - Direct instillation into the lungs during respiratory tract manipulations.
  - There is no man-to-man transmission.
- **Predisposing factors for *Legionella* infections include:**
  - Smoking, alcoholism and chronic lung disease—impair mucociliary clearance.
  - Advanced age.
  - Immunosuppression-transplantation, HIV infection, steroid therapy.
  - Prior hospitalization.
  - Patients with nasogastric tubes or those undergoing surgery with general anesthesia promotes aspiration.

Pathogenesis

After Legionellae enter the lungs through aspiration or direct inhalation, the following events take place:

- Attachment to the respiratory mucosa is mediated by bacterial type IV pili, heat-shock proteins, a major outer-membrane protein, and complement.
- Both macrophages and neutrophils are recruited to the local sites.
- **Coiling phagocytosis:** Alveolar macrophages phagocytose legionellae by a coiling mechanism.
- Evades intracellular killing by inhibiting phagosome-lysosome fusion.
- Because of their intracellular location, humoral immunity plays a minor role. Cellular immunity is responsible for the recovery.

Clinical Manifestations

Pontiac Fever

It is an acute, flu-like illness characterized by malaise, fever, and headache. Incubation period is about 24–48 hours. It is self-limiting, never develops into pneumonia.

Legionnaires' Disease (Pneumonia)

It is an interstitial atypical pneumonia with incubation period about 2–10 days.

- It is characterized by non-productive cough (with or without blood tinged), dyspnoea, chest pain, high fever and diarrhea.
- Chest X-ray shows pulmonary infiltrates.
- Most common neurologic abnormality is confusion or changes in mental status.
- Legionella is among the leading causes of pneumonia both in the community and hospital settings.
  - It is the fourth common cause of community-acquired pneumonia, accounting for 2–9% of cases.
  - It is responsible for 10–50% of cases of nosocomial pneumonia when a hospital's water system is colonized with the organisms. Serogroup 6 is more commonly involved in hospital outbreaks.

Extrapulmonary Legionellosis

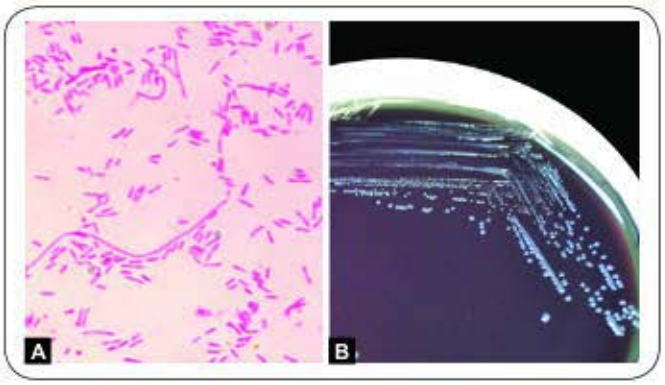
Usually it results from blood-borne dissemination from the lung.

- The most common extrapulmonary site is heart (myocarditis, pericarditis and prosthetic valve endocarditis).
- Other manifestations include sinusitis, peritonitis, pyelonephritis, skin and soft tissue infection.

Laboratory Diagnosis

Useful specimens for Legionnaires' disease include sputum, bronchoalveolar lavage fluid, bronchial wash and pleural fluid.

- **Direct Microscopy**
  - **Gram stain** reveals numerous neutrophils but no organisms (as legionellae are poorly stained, often missed or sometimes appear as faint pleomorphic gram-negative rods or coccobacilli) (Fig. 36.3A).
  - Silver impregnation and Giemsa stains can be used.
  - Direct immunofluorescence test using monoclonal or polyclonal sera is more specific but sensitivity is poor than culture. It is more useful in advanced stage of disease.



Figs 36.3A and B: *Legionella:* **A.** Gram-staining; **B.** Growth on BCYE agar

Source: Public Health Image Library, A. ID#: 15328/ Dr. Gilda Jones, B. ID#: 11766/ Megan Mathias and J. Todd Parker/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Acid-fast staining: *L. micdadei* is weakly acid fast.

- **Culture:** Culture is highly sensitive (80–90%) and specific (100%) and provides definite diagnosis.
  Buffered charcoal, yeast extract (BCYE) agar: Legionellae are highly fastidious and grow on complex media, such as **BCYE agar** (pH 6.8–6.9) (Fig. 36.3B).
  - Plates are incubated at 37°C in 5% CO_2 for 3–5 days.
  - Colonies are round with an entire edge, glistening, convex, green or pink iridescent and have granular or speckled opalescence resembling ground glass.
- **Biochemical tests:** They are motile, catalase positive and oxidase negative. Hippurate hydrolysis test is positive for only *L. pneumophila*. Autofluorescence of colonies under long-wavelength UV can be used for speciation.
- **Antibody detection:** Primarily, serology is used for epidemiologic purpose.
  - Indirect immunofluorescent antibody test and enzyme immunoassays are available.
  - A single titer of more than 1:128 or fourfold rise in titer is considered as significant.
  - Antibodies usually appear late after 12 weeks.
  - Cross-reactivity has been observed with other *Legionella* species.
- **Urinary antigen:** Enzyme immunoassays are available to detect *L. pneumophila* serogroup 1 specific soluble antigens in urine. Advantages include as follows:
  - It is rapid, cheaper, easy to perform.
  - Next to culture, it is highly sensitive, and specific.
  - Antigen in urine is detectable 3 days after the onset and disappears over 2 months.
  - The test is not affected by prior antibiotic administration.
- **Molecular methods:** Polymerase chain reaction (PCR) has been proven useful in the identification of *Legionella* from environmental water.

TREATMENT **Legionnaires' disease**

Macrolides (especially azithromycin) and the respiratory quinolones are now the antibiotics of choice.

Prevention

Routine environmental culture of hospital water supplies is recommended.

- In aquatic environment, *L. pneumophila* can form microcolonies within biofilms; its eradication from drinking-water systems requires disinfectants that can penetrate the biofilm.
- Disinfection of the drinking water by: (1) superheat-and-flush method; (2) commercial copper and silver ionization systems.

DONOVANOSIS

Donovanosis, also called *granuloma inguinale*, is a sexually transmitted disease caused by *Klebsiella granulomatis* (it shows 98% gene homology with *Klebsiella*). However, many authors still recommend to use the old name—*Calymmatobacterium granulomatis*.

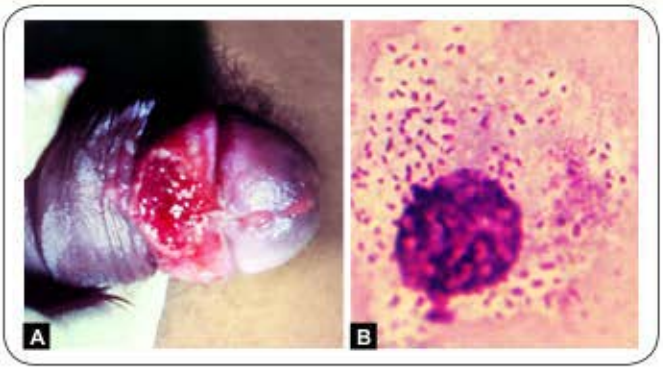
- Disease was first described in Calcutta (now Kolkata) by McLeod in 1882, and the characteristic pathological finding "Donovan bodies" in the genital lesion was recognized by Charles Donovan in Madras (now Chennai) in 1905.
- Donovanosis is prevalent in India, Brazil, Papua New Guinea and parts of South Africa.
- Risk factors include poor hygiene, lower socioeconomic status and multiple sex partners.
- Globally, the incidence of donovanosis has greatly decreased.

Clinical Features

- Incubation period is about 1–4 weeks (may be up to 6 months). It runs a chronic course.
- Lesion starts as a painless papule which subsequently becomes a **beefy red ulcer** that bleeds readily when touched (Fig. 36.4A).
- Most common sites, genitals are affected in 90% of patients affecting prepuce, frenum and glans in men and the labia minora in women.
- Lymph node involvement is rare however, *pseudobubos* may be seen in the inguinal region in 10% of cases due to subcutaneous abscess.

Laboratory Diagnosis

- **Clinical diagnosis** is made by the appearance of characteristic lesion.
- **Specimen collection:** A swab should be rolled firmly over an ulcer previously cleaned with a dry swab to



Figs 36.4A and B: Donovanosis. **A.** Beefy red ulcer; **B.** Donovan bodies: Cyst-like macrophages filled with deeply stained capsulated bacilli having a safety-pin appearance (Giemsa stain)

Source: Public Health Image Library: A. /ID#:5363/ Dr. Tabua; B. ID#: 18899, Susan Lindsley/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

remove debris. Alternatively, a piece of granulation tissue crushed and spread between two slides can be used.

- **Direct microscopy:** Smears can be examined after a rapid Giemsa or Wright's stain.
  - Donovan bodies can be seen as large cyst like macrophages filled with deeply stained capsulated bacilli having a *safety-pin* (bipolar) appearance (Fig. 36.4B). These cysts eventually rupture releasing the bacilli.
  - They are non-motile, capsulated and gram-negative bacilli.
- **Culture:** They can be grown on egg yolk medium and on HEp-2 cell lines.
- **Molecular Method:**
  - PCR has been developed to differentiate *Klebsiella granulomatis* from other *Klebsiella* species by detecting unique base changes in the *phoE* gene.
  - A genital ulcer multiplex PCR has been developed for simultaneous detection of agents of common genital ulcers such as donovanosis, syphilis, chancroid, lymphogranuloma venereum and genital herpes.

TREATMENT — Donovanosis

- Macrolides are drug of choice. Azithromycin is given 1 g on day 1, then 500 mg daily for 7 days.
- Alternatively, doxycycline (100 mg twice a day) or tetracycline (500 mg twice a day) is given for 14 days.
- Both the sexual partners should be treated.

GARDNERELLA VAGINALIS

Gardnerella vaginalis (formerly known as *Haemophilus vaginalis* or *Corynebacterium vaginale*) is normally isolated from the normal female genital tract in low numbers. When outnumbered, causes a condition called **bacterial vaginosis**.

- It is gram-negative (appears gram variable in smears), nonmotile, small pleomorphic rod, which shows metachromatic granules.
- It produces minute haemolytic colonies on blood agar, incubated aerobically under 5% CO_2 for 24–48 hours.
- It is catalase, oxidase, indole and urease negative.

Bacterial Vaginosis

Organisms Associated

Bacterial vaginosis affects women of reproductive age. This condition is associated with an alteration of the normal vaginal flora, which is as follows.

- Increase in the concentrations of:
  - *Gardnerella vaginalis*
  - *Mobiluncus* (motile, curved, gram-variable or gram-negative, anaerobic rods)
  - Several other anaerobes [*Prevotella* and some *Peptostreptococcus*]
  - *Mycoplasma hominis*
- Decrease in the concentrations of lactobacilli (lactobacilli usually maintain the acidic pH of the vagina, thereby inhibiting the growth of pathogenic organisms).

Risk Factors

Bacterial vaginosis is associated with the following risk factors.

- Coexisting other infections such as HIV, *Chlamydia trachomatis*, and *Neisseria gonorrhoeae*
- Recent unprotected vaginal intercourse
- Vaginal douching
- Premature rupture of membranes and preterm labor.

Laboratory Diagnosis

Bacterial vaginosis is so named because there is no associated inflammation. It is clinically diagnosed by *Amsel's criteria* (see below in box).

Amsel's Criteria

Bacterial vaginosis is diagnosed if any 3 of the following 4 findings are present:

1. Profuse thin (low viscous), white homogeneous vaginal discharge uniformly coated on vaginal wall
2. pH of vaginal discharge more than 4.5
3. Accentuation of distinct fishy odor (attributable to volatile amines such as trimethylamine) immediately after vaginal secretions are mixed with 10% solution of KOH (*Whiff test*).
4. **Clue cells:** They are vaginal epithelial cells coated with coccobacilli, which have a granular appearance and indistinct borders observed on a wet mount (Fig. 36.5).

Nugent's score: It is a scoring system followed for the diagnosis of bacterial vaginosis; done by counting the number of *Gardnerella vaginalis, Mobiluncus* and lactobacilli present in the Gram-stained smear of vaginal discharge. A score of more than or equal to 7 is diagnostic.

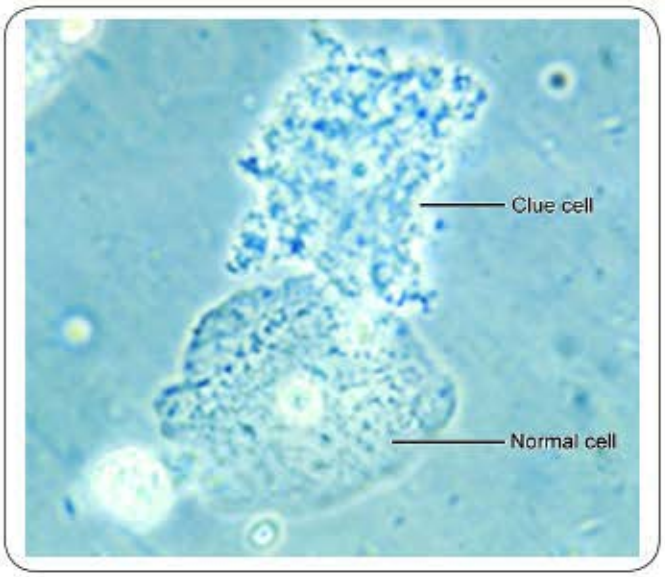


Fig. 36.5: Wet mount of vaginal secretion depicting clue cell

Source: Public Health Image Library/ID#: 14574/ M. Rein /Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Bacterial vaginosis**

Drug of choice is oral metronidazole, given 500 mg twice daily for 7 days.

RAT BITE FEVER

Rat-bite fever is characterized by septic fever, petechial rashes, and very painful polyarthritis with frequent relapses. It is caused by either of these two pathogens:

- *Streptobacillus moniliformis*
- *Spirillum minus*

Streptobacillus moniliformis

S. moniliformis is present as normal flora in the throat of rats; however, it can be a pathogen of many rodents including guinea pigs and mice.

Clinical Manifestations

- Humans can be infected by rat bites. Ingestion of raw milk or water contaminated with rats can also transmit the infection.
- The disease has occurred in epidemics in Haverhill (USA) and, hence, called *Haverhill fever* or *erythema arthriticum epidemicum.*

Laboratory Diagnosis

Useful specimens are blood, joint fluid or pus.

- **Microscopy:**
  - It is gram-negative, highly pleomorphic nonmotile organism.
  - Forms irregular chains of gram-negative bacilli with beaded or fusiform swellings readily developing into L-forms.
- **Culture:**
  - It grows best at 37°C aerobically, in media containing serum protein, egg yolk, or starch.
  - L-forms are frequently formed in fresh cultures, which revert back to streptobacilli when subcultured in liquid media.
- All strains of streptobacilli appear to be antigenically identical.
- Other methods include: Mouse inoculation and serum agglutination tests.

Spirillum minus

Rat-bite fever is caused by *Spirillum minus.* It is called **sodoku** in Japan. It was first observed in a rat by Carter (1888) in India.

Clinical Features

Clinical features are similar to that of streptobacillary rat bite fever except (Table 36.1):

- Longer incubation period of 1–4 weeks.
- Enlarged lymph nodes

Laboratory Diagnosis

- **Microscopy:** These are very small (3–5 μm) and rigid, spirally coiled bacilli.
  - Motile with 1–7 amphitrichous flagella.
  - Gram-negative but is better visualised by Giemsa or Fontana stains or by dark field microscopy.
- **Culture:** *Spirillum* cannot be cultured in artificial culture media. However, it can be isolated by inoculation into guinea pigs or mice with material from enlarged lymph nodes or blood.

TABLE 36.1: Types of rat bite fever

	Streptobacillary rat bite fever	Spirillary rat bite fever
Agent	*Streptobacillus moniliformis*	*Spirillum minus*
Disease also known as	Haverhill fever (USA)	Sodoku (Japan)
Incubation period	7–10 days	1–3 weeks
Clinical features	1. Septic fever 2. Skin rashes 3. Painful polyarthritis 4. Frequent relapses	Similar features with additional lymph node enlargement
Gram-staining	Gram-negative, highly pleomorphic bacilli in chain	Gram-negative, spirally coiled bacilli
Motility	Nonmotile	Motile
Artificial media	Cultivable	Noncultivable
Drug of choice	Penicillin	Penicillin

TREATMENT **Rat bite fever**

- **Drug of choice:** Penicillin is considered to be the treatment of choice for both the agents.
- **Alternative drugs** that can be used are: streptomycin, tetracycline, doxycycline, cephalosporin.
- Penicillin resistance, though rare, has been reported for *S. moniliformis*.

FRANCISELLA TULARENSIS

Francisella tularensis is the causative agent of 'tularemia' primarily a plague-like disease of rodents and other small animals.

Epidemiology

- **Source:** It persists in contaminated environments, insects, and animal carriers.
- **Transmission:** Human infection is zoonotic and usually results from:
  - Interaction with biting or blood-sucking insects (especially ticks and tabanid flies)
  - Contact with wild or domestic animals
  - Ingestion of contaminated water or food
  - Inhalation of infective aerosols

Prevalence

F. tularensis has four subspecies: *tularensis, holarctica, novicida,* and *mediasiatica*.

- The first three subspecies are found in North America, whereas subspecies *mediasiatica* is found in central Asia.
- Subspecies *tularensis* is the most common and the most virulent among all. It has been isolated only from North America, where it accounts for more than 70% of cases.
- Increasing number of cases due to other subspecies have been reported from the Scandinavian countries, Eastern Europe, and Siberia.

Clinical Manifestations

Tularemia is characterized by various clinical syndromes:

- **Ulceroglandular tularemia:** It is the most common form, accounting for 75–85% of total cases, characterized by ulcerative lesion at the site of inoculation, with regional lymphadenopathy.
- **Pulmonary tularemia:** It can result from aerosol inhalation (laboratory workers) or can spread to the lungs following bacteremia. Patients present with atypical pneumonia.
- **Oropharyngeal tularemia:** It occurs following ingestion of contaminated undercooked meat. It is characterized by membranous pharyngitis with cervical lymphadenopathy. ***Lemming fever*** in Norway results from consumption of water contaminated with excreta of infected lemmings.
- **Oculoglandular tularemia:** It is characterized by purulent conjunctivitis with preauricular lymphadenopathy.
- **Typhoid-like** illness
- **Agent of bioterrorism:** Because of the highly infectious nature, *F. tularensis* is currently classified as category A agent of bioterrorism.

Laboratory Diagnosis

- **Culture:** Isolation is very difficult as *F. tularensis* is highly fastidious.
  - It needs special media, such as:
    - BCG agar (blood cysteine glucose agar)
    - CHAB agar (cysteine heart agar supplemented with 9% heated sheep blood)
  - **Specimen:** Ulcer scrapings, lymph node biopsy, gastric washings, sputum, and blood are inoculated onto the media and incubated at 37°C for 2–4 days aerobically as *F. tularensis* is an obligate aerobe.
  - Colonies are blue-gray, round, smooth, and slightly mucoid with small zone of α-hemolysis.
  - Safety precautions such as biosafety level III must be used to handle clinical specimens to avoid the risk of laboratory-acquired infection.
- **Identification:**
  - *F. tularensis* is a small gram-negative coccobacillus with bipolar appearance, nonmotile and capsulated.
  - It is weakly catalase positive, oxidase negative and H_2S positive.
  - It produces acid but not gas from glucose, maltose and mannose.
  - Direct fluorescent antibody tests can be done with commercially available antisera, directly from the culture colonies for subspecies identification.
- **Antibody detection** is the mainstay of diagnosis as isolation is difficult. Agglutination tests (latex and tube agglutination) and ELISA formats are available.
- **PCR assay** has been used to detect *F. tularensis* specific genes encoding the outer-membrane proteins. It can also differentiate subspecies.

TREATMENT **Tularensis**

Gentamicin is considered as the drug of choice; given 5 mg/kg for 7–10 days.

PASTEURELLA

Pasteurella species are primarily harbored in respiratory tracts of many animals and some time cause fatal diseases including hemorrhagic septicemia in animals.

- *Pasteurella multocida* is probably the most common organism in human wounds inflicted by the bites of cats and dogs.

- Other species such as *P. haemolytica* and *P. pneumotropica* rarely infect humans. *P. aviseptica* is the chicken cholera bacillus, used by Louis Pasteur for the development of first attenuated bacterial vaccine hence the name *Pasteurella* was coined.

Clinical Findings

Following animal bite (most common mode of transmission), the affected area becomes red, swollen and painful with variable regional lymphadenopathy and low grade fever.

Pasteurella is present as a commensal in human respiratory tract and infection may occur following trauma or surgeries that leads to bacteremia or systemic manifestations, such as:

- Meningitis (following head injury)
- Appendicitis
- Chronic respiratory infection

Laboratory Diagnosis

- *Direct microscopy* of wound swabs shows nonmotile gram-negative coccobacilli with a bipolar staining.
- *Culture*: They are aerobes or facultative anaerobes that grow readily on ordinary media like nutrient agar at 37°C.
- They resemble yersiniae; however, they differ from the latter in being:
  - Oxidase-positive
  - Indole-positive
  - Failure to grow on MacConkey agar.

TREATMENT — ***Pasteurella***

Penicillin G is considered as the drug of choice for *P. multocida* infections.

CHROMOBACTERIUM VIOLACEUM

It is a saprophyte of water and soil in tropics. It occasionally causes skin lesions, sepsis, and liver abscesses.

- It is a motile, gram-negative, facultative anaerobe, nonsporing, coccobacillus.

Fig. 36.6: Violet-colored colonies of *Chromobacterium violaceum* on blood agar

Source: Public Health Image Library, ID#:12434/Amanda Moore/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- It produces characteristic violet color nondiffusible pigment (called **violacein**) (Fig. 36.6).

CAPNOCYTOPHAGA SPECIES

Several species such as *C. ochracea*, *C. gingivalis* and *C. sputigena* have been a part of human mouth flora.

- They occasionally cause periodontal diseases, and sepsis in immunocompromised hosts.
- Certain species such as *C. canimorsus* and *C. cynodegmi* are commensals in mouth of dogs and are transmitted by dog bites.

Laboratory Diagnosis

- They are fusiform or filamentous gram-negative coccobacilli.
- Highly fastidious, require carbon dioxide for optimal growth.
- They produce yellow orange pigment.
- They lack flagella but exhibit *gliding motility* on agar surface.

TREATMENT — ***Capnocytophaga***

Due to their ability to produce β lactamases, ampicillin/sulbactam combination is the drug of choice.

EXPECTED QUESTIONS

I. Write short notes on:

1. Laboratory diagnosis of *Helicobacter pylori*
2. Donovanosis
3. Pathogenesis of *Legionella pneumophila*
4. Bacterial vaginosis
5. Rat bite fever

II. Multiple Choice Questions (MCQs):

1. Most common mode of transmission of *Legionella pneumophila* is:
a. Aspiration b. Ingestion
c. Insect bite d. Blood

2. Most sensitive and accurate method of diagnosis of *Helicobacter pylori* is:
a. Culture b. Biopsy urease test
c. Histopathology d. Urea breath test

3. Rat bite fever is caused by:
a. *Borrelia recurrentis* b. *Streptobacillus moniliformis*
c. *Yersinia pestis* d. *Leptospira*

4. Wrong about Bacterial vaginosis is:
a. Discharge has offensive smell
b. pH >4.5
c. Causative agent is *Chlamydia trachomatis*
d. Clue cell is diagnostic

Answers

1. a **2.** d **3.** b **4.** c

CHAPTER 37

Spirochetes

Chapter Preview

- Classification and morphology
- Treponema
  - T. pallidum (agent of Syphilis)
  - Non-venereal treponematoses
- Borrelia
  - B. recurrentis (relapsing fever)
  - B. burgdorferi (lyme disease)
  - B. vincentii (vincent's angina)
- Leptospira (Weil's disease)

CLASSIFICATION AND MORPHOLOGY

Spirochetes are thin, flexible, elongated spirally coiled helical bacilli (*speira*, meaning coil; and *chaite*, meaning hair). They belong to the order Spirochetales that comprises of two classes:

1. Class Spirochaetaceae: It consists of four genera: *Spirocheta, Cristispira, Treponema, Borrelia*
2. Class Leptospiraceae: It consists of the following two genera: *Leptospira, Leptonema*

Most of the spirochetes are saprophytes. Only three of them are major human pathogens—*Treponema*, *Borrelia* and *Leptospira*.

Ultrastructure of Spirochetes (Figs 37.1A to E)

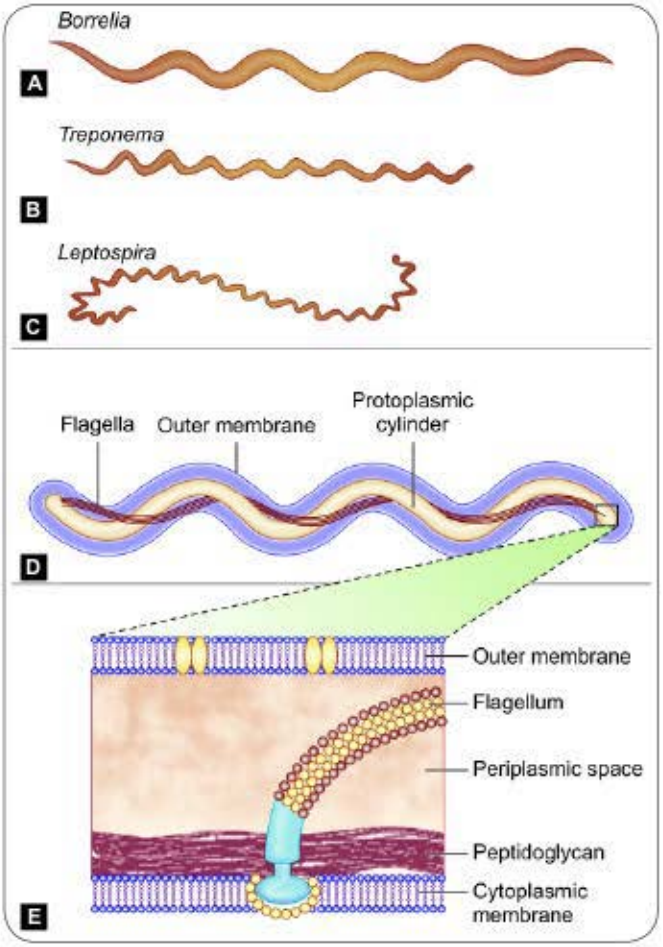
The cell wall of spirochetes is similar to that of gram-negative bacteria but differs by bearing endoflagella. It is more complex, consisting of:

- Outer membrane
- Periplasmic space containing flagella
- Peptidoglycan layer
- Inner (cytoplasmic) membrane

Endoflagella and Motility

The characteristic feature of spirochetes is that the flagella are internal, present in the periplasmic space between the outer membrane and the peptidoglycan layer.

- They attach to the membrane only at the pole.
- The number of periplasmic flagella varies from species to species.
- Endoflagella are responsible for the motility of spirochetes. Motility may be of various types, such as:
  - Flexion-extension type
  - Corkscrew type rotatory movement
  - Translatory type
- Spirochetes can swim even in highly viscous, gel-like medium, such as that found in connective tissues, where the motility of most other bacteria is inhibited.



Figs 37.1A to E: Ultra structure of Spirochetes. **A. to C.** General shape; **D.** Magnified view; **E.** Cross-sectional view

Pathogenic spirochetes, such as *Treponema*, *Borrelia* and *Leptospira* can vary from each other in various aspects (Tables 37.1 and 37.2):

- **Relative size:** Spirochetes vary widely in size from 5 µm to 500 µm in length.
- **Spirals:** Number of spirals, spiral width (wavelength) and amplitude (or depth) of spirals.
- **Staining property:** Larger spirochetes like *Borrelia* are gram-negative but other spirochetes cannot be stained by routine staining methods. However, they can be seen under dark ground microscopy, silver impregnation method and immunofluorescence.
- Number of endoflagella at each pole
- Disease potential
- Mode of transmission.

TABLE 37.1: Morphological differences between *Treponema*, *Borrelia* and *Leptospira*

	Treponema	*Borrelia*	*Leptospira*
Size	6–14 µm × 0.2 µm	10–30 µm × 0.2-0.5 µm	6–20 µm × 0.1 µm
Spirals (in number)	6–12	3–10	Numerous and tightly coiled with hooked ends
Wavelength	1 µm	3 µm	0.5 µm
Amplitude of spiral	1–1.5 µm	Up to 2 µm	0.1 µm
Endoflagella at each pole	3–4	7–11	1
Staining	Do not take up ordinary stains; can be stained only by sliver impregnation stains, except *Borrelia* which is poorly Gram-stained.		

TABLE 37.2: Pathogenic spirochetes

Spirochetes	Disease	Transmission
Treponema		
T. pallidum	Syphilis	Sexual
T. pertenue	Yaws	Direct contact
T. endemicum	Endemic syphilis	
T. carateum	Pinta	
Borrelia		
B. recurrentis	Relapsing fever (epidemic)	Louse borne
B. duttonii, *B. hermsii*	Relapsing fever (endemic)	Tick borne
B. burgdorferi	Lyme disease	Tick borne
B. vincentii	Vincent's angina	Direct contact
Leptospira		
L. interrogans	Leptospirosis ▪ Milder form ▪ Severe form (Weil's disease)	Contact with rodent urine

TREPONEMA

Treponemes are slender spirochetes with fine spirals having pointed ends (*trepos*, meaning 'turn' and *nema*, meaning 'thread').

Most of them are commensals in mouth and genitalia; while few are pathogenic to men, such as:

- *T. pallidum* subspecies *pallidum*
- *T. pallidum* subspecies *pertenue*
- *T. pallidum* subspecies *endemicum*
- *T. carateum*

These pathogenic treponemes are almost identical in their morphology, antigenic structure and in genetic composition. It has been well accepted that the subspecies *pallidum*, *pertenue* and *endemicum* are the evolutionary variations of a single species *T. pallidum*. For the sake of convenience, they are referred hereafter as *T. pallidum*, *T. pertenue* and *T. endemicum*.

TREPONEMA PALLIDUM (AGENT OF SYPHILIS)

Treponema pallidum is the causative agent of an ancient sexually transmitted disease 'syphilis'. The name *pallidum* refers to its pale-staining property.

- **Morphology:** Treponemes are extremely thin and delicate with tapering ends.
- **Size:** They vary in size (6–14 µm × 0.2 µm).
- **Spirals:** They are flexible, spirally coiled around the long axis; possess 6–14 spirals spaced at intervals of 1 µm with amplitude of 1–1.5 µm.
- **Motility:** They are actively motile exhibiting flexion extension, translatory, and corkscrew motility. They have a typical tendency to bend at right angle at the midpoint.
- **Endoflagella:** About 3–4 flagella are present in periplasmic space. They provide motility to the bacteria, thus helping in tissue invasion and dissemination. They are also highly antigenic, stimulating a strong early antibody response.
- **Microscopy:** Treponemes cannot be visualized by light microscope but can be seen under dark ground or phase contrast microscope.
- **Staining:** They do not take up the ordinary stain but can be stained by fluorescence staining and sliver impregnation methods (which increase the thickness of the bacilli).
- **Cultivation:** Pathogenic treponemes cannot be grown in artificial culture media but are maintained by subcultures in susceptible animals such as rabbit testes.
  - Nichols strain, a virulent *T. pallidum* strain was isolated from a case of tertiary syphilis (1912) and has been maintained thereafter in rabbit testes for several decades.

- However, non-pathogenic *Treponemes* such as *T. phagedenis* (Reiter's treponemes) and *T. refringens* (Noguchi strain) can be grown in various media, such as **Smith Noguchi medium** under strict anerobic conditions.

- **Antigens:** *T. pallidum* is antigenically complex and poorly understood. Based on the type of antibody response, three antigens are identified:
  1. **Group-specific antigen:** It is protein antigen present in all treponemes (pathogenic and nonpathogenic). Antibodies to this antigen can be detected in sera of syphilitic patients by using antigens of Reiter treponemes.
  2. **Species-specific antigen:** It appears to be polysaccharide in nature. Treponemal antibodies induced by this antigen in a syphilitic patient can be detected by using specific *T. pallidum* antigens.
  3. **Non-specific antigen:** It is a heterophile antigen. Antibody against this antigen is detected (by using beef heart antigen) by various non treponemal tests described in the proceeding text.

PATHOGENESIS OF SYPHILIS

Syphilis is one of the ancient sexually transmitted disease known since fifteenth century. Name was derived from a famous poem in the year 1530 which described a legend of a shepherd boy named Syphilus, who had suffered from the disease.

- **Mode of transmission:** Venereal syphilis is acquired by sexual contact. However, it can also be transmitted by non-venereal modes such as direct contact, blood transfusion or transplacental transmission.
- **Spread:** *T. pallidum* rapidly penetrates through the minute abrasions on the skin or mucosa and, within a few hours, enters the lymphatics and blood to produce systemic infection and metastatic foci long before the appearance of a primary lesion. Blood is infectious even during the incubation period or in the early stage of syphilis.
- **Incubation period** is variable (9–90 days) and is inversely proportional to the number of organisms inoculated. The median incubation period in humans is about 21 days which corresponds to an average inoculum of 500–1000 infectious organisms.

CLINICAL MANIFESTATIONS OF SYPHILIS

Approximately, 30% of persons who have sexual exposure with an infected partner develop syphilis. Clinically, patients suffering from syphilis pass through four stages if left untreated: primary, secondary, latent and tertiary (or late) stages. Apart from this, if transmitted vertically, the newborn babies develop a congenital form of syphilis.

Fig. 37.2: Primary syphilis (hard chancre)

Source: Public Health Image Library, ID# 6803, Dr/M. Rein/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Primary Syphilis

Primary syphilis is characterized by:

- **Primary (or hard) chancre:** It usually begins as a single painless papule that rapidly becomes ulcerated, hard, and indurated. It is covered by thick exudate, very rich in spirochetes. The most common sites are penis (in males), cervix or labia (in females), and anal canal, rectum or mouth (in homosexuals) (Fig. 37.2).
- **Regional (usually inguinal) lymphadenopathy** appears within 1 week of onset of skin lesions. Lymph nodes are painless firm, non-suppurative, and often bilateral.
- The chancre generally heals within 4–6 weeks (range 2–12 weeks), but lymphadenopathy may persist for months.
- If acquired by non-venereal mode, then the primary syphilis is presented as follows:
  - If transmitted by direct contact→the primary chancre is extragenital, usually on the fingers.
  - If transmitted by blood transfusion→the primary chancre does not occur.

Secondary Syphilis

Secondary syphilis usually develops 4–8 weeks after the healing of primary lesion. Skin and mucous membranes are commonly affected and characterized by:

- **Skin rashes** (palms and soles Fig. 37.3A).
- **Condylomata** lata (mucocutaneous papules which coalesce to form large pink to grey lesions in warm moist intertriginous areas (such as perianal region, vulva, and scrotum) (Fig. 37.3B).
- **Mucous** patches (superficial mucosal erosions Fig. 37.3C).

Figs 37.3A to C: Clinical manifestations of secondary syphilis. **A.** Skin rashes; **B.** Condylomata lata and **C.** Mucosal patch

Source: Public Health Image Library/A-ID# 6808, B- ID# 4098 and C- ID# 481kl6/Centres for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Generalized lymphadenopathy is seen. Chancre may also persist in up to 1/3rd cases.

Latent Syphilis

Latent syphilis is characterized by absence of clinical manifestations of syphilis with positive serological tests for syphilis and normal CSF findings.

- Latent syphilis may be early latent syphilis (occurs within first year after infection) and late latent syphilis (occurs after the first year of infection).
- Patients are still infectious transmitting the infection either by bloodstream or *in utero*.
- Latent syphilis may have one of the following fates:
  - Persistent lifelong infection (common)
  - Development of late syphilis (rare)
  - Spontaneous cure.

Late or Tertiary Syphilis

Several decades after the initial infection, about one-third of untreated patients develop tertiary syphilis, of which 15% develop gummatous lesions, about 10% develop cardiovascular lesions and remaining 10% develop neurosyphilis. The latter two stages are sometimes classified as *quaternary syphilis*.

- **Gumma (late benign syphilis):** Gummas are locally destructive granulomatous lesions. They can occur in any organ but most commonly seen in bone and skin.
- **Neurosyphilis:** Though neurosyphilis is generally considered as a part of late syphilis, invasion of CNS occurs early within first few weeks of infection, which is followed by years of asymptomatic period. Common manifestations include:
  - Meningeal syphilis (meningitis)
  - Meningovascular syphilis (vasculitis of arteries leading to embolic stroke)
  - General paresis of insane
  - Tabes dorsalis (demyelination of the posterior columns)
- **Cardiovascular syphilis:** Characterized by aneurysm of ascending aorta and aortic regurgitation.

Congenital Syphilis

Though transmission of infection across the placenta may occur at any stage of pregnancy, but fetal damage occurs only after fourth month of gestation. Untreated cases of early maternal syphilis are at higher risk. Antenatal screening and treatment of positive cases during pregnancy may prevent congenital syphilis.

Manifestations of congenital syphilis include:

- **Earliest manifestations** occur within 2 years of age. Affected children are infectious and they suffer from rhinitis (or snuffles), mucocutaneous lesions, bone changes, hepatosplenomegaly and lymphadenopathy.
- **Late congenital syphilis** occurs after 2 years and is noninfectious. It is characterized by interstitial keratitis, eighth-nerve deafness, bilateral knee effusions (Clutton's joints). **Residual stigmata** may remain for long time such as:
  - Hutchinson's teeth (notched central incisors)
  - Mulberry molars
  - Saddle nose, and saber shins.

LABORATORY DIAGNOSIS OF SYPHILIS

Laboratory diagnosis of syphilis consists of demonstration of treponemes, detection of antibodies and PCR.

LABORATORY DIAGNOSIS	Syphilis
Microscopy	
▪ Dark ground microscopy	
▪ Direct IF staining for *T. pallidum* (DFA-TP)	
▪ Silver impregnation method	
• Levaditi stain (for tissue section)	
• Fontana stain (smear)	
Culture: Not cultivable, maintained in rabbit testes	
Serology (antibody detection)	
▪ ***Non treponemal or STS (standard tests for syphilis):*** (reagin antibodies are detected by using cardiolipin antigen)	

Contd...

Contd...

LABORATORY DIAGNOSIS — Syphilis

- Old methods: Wassermann test (CFT) and Kahn Test
- Newer methods (slide flocculation tests):
  - VDRL(Venereal disease research laboratory) test
  - RPR (Rapid plasma reagin)
  - TRUST (toluidine red unheated serum test)
  - USR (Unheated serum reagin test)
- ***Specific/Treponemal test:*** Specific antibodies are detected by using *T.pallidum* antigens
  - TPI (*Treponema pallidum* immobilization test)
  - FTA-ABS(Fluorescent treponemal antibody absorption test)
  - TPA (*T.pallidum* agglutination test)
  - TPIA (*T.pallidum* immune adherence test)
  - TPHA (*T.pallidum* hemagglutination test)
  - TPPA (*T.pallidum* particle agglutination test)
- ***Group specific:*** RP CFT (Reiter protein Complement fixation test)-uses Reiter strain

Polymerase chain reaction(PCR)

Direct Microscopy (Demonstration of Treponemes)

Treponemes can be demonstrated from the superficial lesions of primary, secondary and congenital syphilis.

- Surface of the chancre is cleaned with saline, gentle pressure is applied at the base of the lesion, and a drop of exudate is collected on a slide.
- Antiseptics or soaps should not be used because they may kill the treponemes.
- Specimens should be free of blood and tissue debris.
- Specimens should be handled cautiously as the lesions are highly infectious.

Dark Ground Microscopy (DGM)

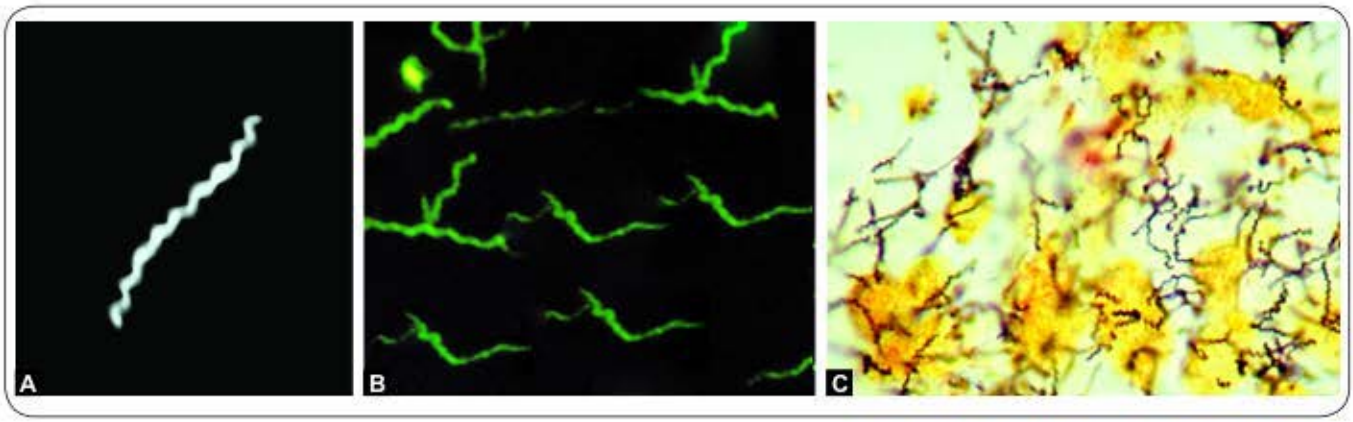
Treponemes cannot be visualized by light microscope but can be seen by examining the wet film of specimen under dark ground (DGM) or phase contrast microscope.

- **Under DGM:** *T. pallidum* appears as slender, flexible, spirally coiled bacilli with tapering ends, measuring 6–20 µm in length and 0.1–0.2 µm in width and contains 6–20 spirals spaced at an interval of 1–1.5 µm wavelength with amplitude of 0.5–0.7 µm (Fig. 37.4A).
- **Motility:** *T. pallidum* shows typical: (i) slow to rapid *flexion-extension type* of movement with (ii) rotation around its longitudinal axis **(corkscrew motility)**, (iii) rotation may be accompanied by a **soft bending** at right angle to the midpoint.
- The **sensitivity** of DGM approaches 80% with a detection limit of 10^4 bacilli/mL.
- **Multiple specimens** should be examined on three consecutive days before declaring DGM to be negative.
- **Saprophytic spirochetes:** Even for the experienced observer, it is difficult to differentiate *T. pallidum* from other saprophytic spirochetes of the genital area, such as *T. refringens* (shows very active serpentine-like movement), and *T. phagedenis* (shows jerky movement). Differentiation is based on size, spiral character and motility.

Direct Fluorescent Antibody Staining for T. pallidum (DFA-TP)

Smear made from the exudate is stained with fluorescent-labelled monoclonal antibody targetted against *T. pallidum* surface antigens.

- *T. pallidum* appears as distinct, sharply outlined, apple green fluorescent color bacilli (Fig. 37.4B).
- Sensitivity of DFA-TP test approaches 100% when smear made from fresh lesions are examined.
- Use of DFA-TP test has been extended to stain the tissue sections (DFAT-TP).



Figs 37.4A to C: Direct microscopy of *T. pallidum*. **A.** Dark ground microscope; **B.** Direct fluorescent antibody staining (DFA-TP) and **C.** Silver impregnation method

Source: Public Health Image Library, A. ID# 2043, B. ID# 14967/Dr Russell, C. ID# 836, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Silver Impregnation Staining

Treponema do not take up ordinary stains as they are extremely thin and delicate (Fig. 37.4C).

- However, silver impregnation methods can be used to increase their thickness.
- Treponemes reduce silver nitrate to metallic silver that is deposited on the surface, making them thicker.
- Levaditi stain is used for staining tissue section and Fontana stain is used for staining smears made from exudates.

Cultivation

Pathogenic treponemes including *T. pallidum* cannot be grown in artificial culture media but are maintained by subcultures in susceptible animals such as rabbit testes.

Serology (Antibody Detection)

As microscopy is difficult and culture methods are not available, antibody detection methods are of paramount importance in the diagnosis of syphilis.

Depending upon the type of antigen used, three types of tests are available to detect antibodies in patient's sera:

- **Non-treponemal tests:** Detect non-specific reagin antibody by using cardiolipin antigen derived from bovine heart.
- **Treponemal tests:** Detect species-specific antibody by using *T. pallidum* specific antigen; which is polysaccharide in nature.
- **Group-specific tests:** Detect group or genus-specific antibody by using Reiter treponemal strains possessing protein antigen, which is present in all treponemes.

Non-treponemal or Non-specific tests or STS (Standard Tests for Syphilis)

Non-treponemal tests detect a characteristic non-specific antibody (called reagin antibody) in the sera of syphilitic patients by using cardiolipin antigen extracted from beef heart.

- Cardiolipin antigen is chemically a diphosphatidyl glycerol. Similar lipid haptens have been detected on the surface of *T. pallidum*.
- However, it is not clear whether the reagin antibodies are induced against the lipid haptens present in *T. pallidum* or to the similar antigens released from the damaged host tissues.
- Such reagin antibodies are IgG or rarely IgM type and are distinct from the IgE class of reagin antibodies seen in type I hypersensitivity reactions.

Various tests have been described, such as:

- Wassermann test (e.g. of complement fixation test) and Kahn test (e.g. of tube flocculation test)—both are no longer in use.
- Slide flocculation tests such as: Venereal Disease Research Laboratory (VDRL), RPR (Rapid Plasma Reagin), USR (Unheated Serum Reagin) TRUST (Toluidine Red Unheated Serum Test).

Venereal Disease Research Laboratory (VDRL)

- This test was named after Venereal Disease Research Laboratory (VDRL), New York, where the test was developed. It is the most widely used, simple and rapid serological test. VDRL antigen is a cardiolipin antigen to which cholesterol and lecithin are added (standardized by Pangborn, 1945). In India, it is prepared at Institute of Serology, Kolkata.

Procedure

- **Antigen preparation:** VDRL antigen has to be reconstituted with a buffer present in the kit and has to be used within 24 hours. This step is needed for maturation and polymerization of the antigen.
- Patient's serum is inactivated by heating at 56°C for 30 minutes to remove the non-specific inhibitors.
- **VDRL slide** containing 12 concave rings are used (Fig. 37.5A).
- **Qualitative test:** 50 µl of inactivated serum is mixed with a drop of VDRL antigen and the slide is rotated at 180 revolutions per minute for 4 minutes in a VDRL rotator and examined under microscope (10x). The results are read as follows:
  - **Non-reactive:** Uniformly distributed fusiform crystals represent the presence of VDRL antigen only, which indicates a negative result.
  - **Reactive:** Presence of medium to large clumps signifies antigen antibody complexes; hence, it indicates a positive result (Fig. 37.5B).
- **Quantitative test:** If the test is found reactive, antibody titer is determined by performing the test with serial dilutions (1:2, 1:4, 1:8 and so on) of serum done with 0.9% saline.
- **VDRL-CSF**: VDRL test can also be performed to detect CSF antibodies. However, no preheating of CSF is needed.

Rapid Plasmda Reagin (RPR)

RPR is another slide flocculation test using disposable plastic cards having 10 clearly defined circles. It is similar to VDRL test with some differences (Tables 37.3 and 37.4).

Unheated Serum Reagin Test (USR)

USR is similar to VDRL except for:

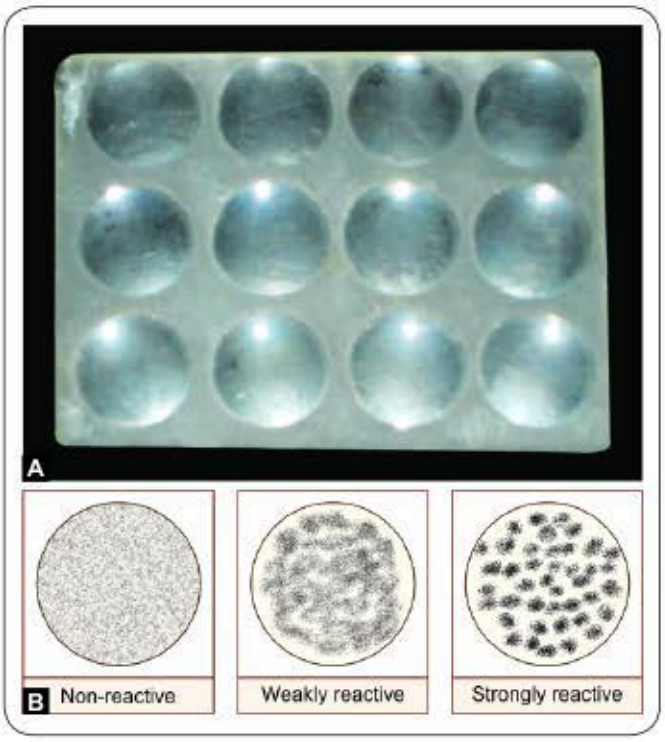
- EDTA is used as antigen stabilizer; hence, daily preparation of antigen is eliminated.
- Choline chloride is used to inhibit the non specific inhibitors in serum; hence pre heating of serum is not needed.

Toluidine Red Unheated Serum Test (TRUST)

TRUST is a modified RPR test where toluidine red pigment particles are used instead of carbon particles. Like RPR test, it does not require microscope for examination.

Advantages of Non-treponemal Tests

- Non-treponemal tests are the most recommended tests to monitor the response to treatment. Reagin tests



Figs 37.5A and B: **A.** VDRL slide and **B.** VDRL test results

TABLE 37.3: Differences between VDRL and RPR tests

VDRL	RPR
Results read microscopically (low power) as clumps are smaller in size	Results read macroscopically: Finely divided **carbon particles** coated with cardiolipin antigens are used so that larger visible clumps are formed
Antigen, once reconstituted, should be used within 24 hours	**EDTA** is used as stabilizer; hence, RPR antigen can be stored longer (up to 6 months at 4–10°C)
Pre-heating of serum is required to remove nonspecific inhibitors	Preheating of serum is not required as **choline chloride** is used to remove inhibitors
Blood, plasma, serum, and CSF can be tested	Blood, plasma and serum can be tested **but not CSF**
Rotation of slide is done for 4 minutes	Rotation of card is done for 8 minutes
Sensitivity in primary syphilis is 78%	Sensitivity in primary syphilis is 86%
It is cheaper; one vial of VDRL antigen can be used for 250 tests. It is preferred for field studies and for antenatal screening	RPR is expensive than VDRL. It is preferred when sample load is less.

Abbreviations: VDRL—Veneral disease research laboratory; RPR—Rapid plasma reagin; EDTA—Ethylenediaminetetraacetic acid; CSF—Cerebrospinal fluid

TABLE 37.4: Sensitivity and specificity of various tests for syphilis

	Sensitivity (%)				Specificity (%)
Treponemal	Primary	Secondary	Latent	Late	
FTA-ABS	84	100	100	96	97
TPPA	88	100	100	*	98
TPHA	76	100	97	94	99
EIA	90	100	100	*	99
Western blot	90	100	100	*	98
Non-treponemal					
VDRL	78	100	95	71	98

USR	80	100	95	*	99
TRUST	85	100	98	*	99

* sensitivity not reported

Abbreviations: FTA-ABS—Fluorescent treponemal antibody absorption; TPPA—Treponema pallidum particle agglutination; TPHA—*T. Pallidum* hemagglutination assay; EIA—Enzyme immuno assay; VDRL—Venereal Disease Research Laboratory; RPR—Rapid Plasma Reagin; USR—Unheated Serum Reagin; TRUST— Toluidine Red Unheated Serum Test

usually become negative 6–18 months after the effective treatment for syphilis, depending on the stage at which treatment is given.

- Neurosyphilis: VDRL can also be used to detect CSF antibodies.
- Reagin antibody becomes detectable 7–10 days after the appearance of primary chancre (or 3–5 weeks after acquiring the infection).
- Sensitivity: The sensitivity of nontreponemal tests varies from 78 to 85% in primary stage, 100% in secondary stage and 95–98% in latent stage.

Disadvantages of Non-treponemal Tests

Biological false-positive (BFP) reactions: BFP reactions are defined as positive results in non treponemal tests, with negative results in treponemal tests, in the absence of syphilis and not caused by technical faults.

- Cardiolipin antigen being non-specific may react with the sera of patients suffering from unrelated diseases but not having syphilis.
- Reagin antibodies are induced against the cardiolipin antigen present in *T. pallidum* or to similar lipid haptens released from the damaged host tissues.
- **Frequency:** These BFP reactions may occur in about 1% of normal sera.
- BFP antibody is usually of IgM type, while reagin antibody in syphilis is mainly IgG.
- BFP reactions may be seen in the conditions such as lepromatous leprosy, relapsing fever, malaria, tropical

pulmonary eosinophilia, viral hepatitis, infectious mononucleosis, HIV, pregnancy and IV drug abusers.

- **Prozone phenomena:** If antibody titer in patient's sera is high, it may lead to false negative result hence it is essential to test sera in dilutions.
- **Sensitivity** of non treponemal tests is low in late stage of syphilis. VDRL-CSF is more reliable for neurosyphilis than VDRL test of serum.
- **Screening tests:** Non-treponemal tests are used as screening tests which should be confirmed by treponemal tests.
  - If treponemal tests are found positive, this confirms syphilis.
  - If treponemal tests are found negative, this indicates false-positive non-treponemal tests.

Treponemal or Specific Tests

All reactive non-treponemal tests must be confirmed by treponemal tests using specific *T. pallidum* antigens to rule out the biological false positive reactions (Table 37.4). Treponemal tests include:

T. pallidum Immobilization (TPI) test (Uses live T. pallidum)

TPI test is based on the ability of patient's antibody and complement to immobilize the live actively motile *T. pallidum* (Nichols strain), observed under dark ground microscope. It was one of the widely used test for syphilis in the past, now not in use.

Fluorescent Treponemal Antibody-Absorption Test (FTA-ABS) (Uses killed T.pallidum)

It is an indirect fluorescent antibody technique.

- The patient's serum is first diluted with an extract of nonpathogenic Reiter treponemes to remove group-specific treponemal antibodies.
- Patient's serum is layered on a slide previously coated with killed *T. pallidum*.
- Serum antibodies bound to *T. pallidum* can be detected by addition of fluorescent labeled anti-human immunoglobulin and then slide is examined under fluorescent microscope.
- **IgM-FTA-ABS test** is another modification used for congenital syphilis. It detects IgM antibodies in fetal serum.
- **Advantages:** FTA-ABS is highly sensitive and specific in all the stages of syphilis and it is the first serological test to be positive following infection. It can also be used to detect CSF antibodies.
- **Disadvantage:** False positive results may occur in Lyme disease (FTA-ABS being positive and VDRL test negative).

Test Using an extract of *T. pallidum*

T. pallidum Hemagglutination Assay (TPHA)

TPHA is usually performed in microtiter plates; hence also called microtiter hemagglutination.

T. pallidum (MHA-TP) test

Patient's serum (pretreated with Reiter treponemes) is added to a drop of tanned sheep RBCs coated with *T. pallidum* antigens.

- **Reactive result:** Smooth mat of agglutinated cells is formed in the wells of microtiter plate.
- **Nonreactive result:** It is reported when compact button is formed in the center of the well.
- **Quantitation** of treponemal antibody can be done by serial dilution of patient's sera.
- **Advantages:** TPHA is affordable, easy to perform, available as commercial kit and no special equipment is needed. It can also be used to detect CSF antibodies. Thus, TPHA has been used as standard confirmatory test worldwide.
- Sensitivity and specificity of TPHA are excellent in all the stages, except for primary syphilis where the sensitivity is low.
- **TPPA:** *T. pallidum* particle agglutination test is a modification of TPHA where gelatin particles are used for sensitizing with *T. pallidum* instead *of tanned* RBCs.

Enzyme Immunoassays

ELISA specific to IgG and IgM have been developed for the diagnosis of syphilis.

- They have excellent sensitivity and specificity.
- IgM ELISA is more sensitive than IgM FTA-ABS for diagnosis of congenital syphilis.

Western Blot

Western blot is available for detecting IgG and IgM antibodies separately. It is highly sensitive and specific.

Group-specific Test

Reiter's protein complement fixation test (RP-CFT): It works on the principle of CFT, detects group- or genus-specific treponemal antibodies against the protein antigen prepared from cultivable Reiter strain. Its sensitivity is low and is obsolete now-a-days.

Molecular Methods

PCR-based techniques are available to amplify *T. pallidum* specific genes, such as gene coding for 47-kDa surface antigen (lipoprotein) and 39-kDa basic membrane protein. PCR is of paramount importance in the diagnosis of congenital and neurosyphilis.

Diagnosis of congenital syphilis

Definitive diagnosis:

Demonstration of *T. pallidum* by DGM of umbilical cord, placenta, nasal discharge, or skin lesion material.

Presumptive diagnosis:

- Infant born to a mother who had syphilis at the time of delivery regardless of findings in the infant.
- Reactive treponemal test in infant
- One of the following additional criteria:
  - Clinical signs/symptoms of congenital syphilis
  - Abnormal CSF findings without other cause
  - Reactive VDRL-CSF test
  - Reactive IgM antibody test specific for syphilis (IgM FTA ABS or IgM ELISA)

Note: As IgM does not cross the placenta, its presence in neonatal serum confirms the diagnosis of congenital syphilis.

Syphilis and HIV

Both syphilis and HIV affect each other's pathogenesis.

- Genital syphilis facilitates the transmission of HIV through the abraded mucosa.
- Patient with HIV, if develops syphilis later→there is rapid progression to late stages of syphilis and neurological involvement even after treatment of primary or secondary syphilis.

Problems in the diagnosis of syphilis in HIV infected people are:

- Confusing clinical signs and symptoms.
- Lack of serologic response in a patient with a clinically confirmed case of active syphilis.
- Unusually high titers in non-treponemal tests perhaps as a result of B-cell activation.
- Failure of non-treponemal test titers to decline even after treatment with standard regimens.
- Disappearance of treponemal test reactivity over time.

TREATMENT Syphilis

- **Penicillin** is the drug of choice for all the stages of syphilis:
  - Primary, secondary, or early latent syphilis: single dose of Penicillin G is given.
  - Late latent CVS or benign tertiary stage: penicillin G is given single dose weekly for 3 weeks.
  - Neurosyphilis or abnormal CSF in any stage or associated HIV-aqueous crystalline or procaine penicillin G is given for 10–14 days.
- **Alternate drug is used** in patients with penicillin allergy:
  - Primary, secondary, latent, CVS or benign tertiary syphilis—tetracycline is recommended.
  - Neurosyphilis or pregnancy or associated HIV—desensitization to penicillin has to be done, following which penicillin is administered.

Evaluation after Treatment

Non-treponemal tests, such as VDRL and RPR are preferred over treponemal tests for monitoring response to treatment. Antibody titers of treponemal tests remain elevated even after clinical improvement. VDRL has to be done at 3 months' intervals for at least 1 year.

- **For primary and secondary syphilis:** Following clinical improvement, there should be at least fourfold decline in the titer by the third or fourth month and an eightfold decline in the titer by sixth to eighth month.
- **Latent or late syphilis, or patients with multiple episodes of syphilis:** It may show a gradual decline in titer, low titers may persist for years.

Prevention

- Treatment of cases and contacts (sexual partners)
- Education about safe sex practices
- Prophylactic use of barrier contraceptive methods.

NON-VENEREAL TREPONEMATOSES

Endemic or nonvenereal treponematoses are caused by three close relatives of *T. pallidum*, out of which the first two are considered as subspecies of *T. pallidum*:

- *T. pertenue* (causes yaws)
- *T. endemicum* (causes endemic syphilis)
- *T. carateum* (causes pinta)

Endemic treponematoses can traditionally be distinguished from venereal syphilis by (Table 37.5):

- Mode of transmission (direct contact, not sexual)
- Age of acquisition (childhood)
- Geographic distribution (rural areas of developing nations of tropics, travelers in developed nations)
- Associated with poor hygiene
- Clinical features (described in the text).

Yaws

Yaws (also known as pian, framboesia, or bouba) is an endemic disease caused by *T. pallidum* subspecies *pertenue*.

- **Epidemiology:** Yaws is endemic in the tropical areas of Africa, South-east Asia, and Central America.
  - In India, cases were found from tribal hilly areas of Odisha, Chhattisgarh, Assam, Andhra Pradesh and Madhya Pradesh.
  - However, India actively participated in yaws eradication programme in 1996 and has reported no new cases since 2003.
- **Transmission** is by direct skin-to-skin contact.
- **Clinical manifestation:** Incubation period is about 3–4 weeks. Yaws is characterized by
  - Primary lesions ("mother yaw"): Extragenital papule on extremities that enlarges in moist warm weather to become papillomatous or raspberry-like (thus the name 'framboesia')

TABLE 37.5: Comparison of venereal syphilis vs non-venereal treponematoses

Feature	Venereal syphilis	Yaws	Endemic syphilis	Pinta
Agent	*T. pallidum*	*T. pertenue*	*T. endemicum*	*T. carateum*
Mode of transmission	Sexual, transplacental blood	Skin-to-skin	Household contacts: kissing, sharing utensils	Skin-to-skin
Age	Adulthood	Early childhood	Early childhood	Late childhood
Primary lesion	Chancre—painless, non-indurated Lymphadenopathy	Papilloma, often ulcerative Lymphadenopathy	Rarely seen	Nonulcerating pruritic papule
Site of lesion	Genital, oral, and anal	Extremities	Oral	Extremities, face
Secondary lesions	Skin rashes Mucosal patches, condylomata lata	Skin lesions—macular or papular periostitis	Oral mucous patches, periostitis, lymphadenopathy	Pintides, pigmented and pruritic
Relapses	~25%	Common	Unknown	None
Late complications	Gummas, CVS and CNS lesions seen	Destructive gummas of skin, bone, cartilage Destruction of nose, maxilla and palate is termed as **gangosa**, No CNS or CVS lesion		Non-destructive, **dyschromic macule** No CNS or CVS lesion

  - Regional lymphadenopathy may be developed
  - Secondary eruptions are more generalized.
- Skin lesions may take several forms such as macular, papular, or papillomatous. Painful lesions on the feet result in a crab-like gait ("crab yaws").
- Periostitis may result in nocturnal bone pain.
- All early skin lesions are infectious.
  - **Late yaws** occurs in 10% of untreated persons, and is manifested by destructive lesions (gumma) of skin, bone, and joints. Destruction of the nose, maxilla, palate and pharynx may be developed, termed as **gangosa**.
  - Relapses are common during the first 5 years.

Endemic Syphilis

Endemic Syphilis (also called by local names: *bejel, siti, dichuchwa, njovera, skerljevo*) is caused by *T. pallidum* subspecies *endemicum.*

- **Epidemiology:** It is endemic in arid areas of Asia (Syria, Saudi, Iraq, and Iran), Africa (Ghana, Mali, Niger, and Senegal) and Australia, but not in Americas.
- **Transmission:** Bejel is transmitted by direct contact, by kissing or by sharing drinking and eating utensils.

Clinical Manifestation

- **Early manifestations:** It starts as oral papule which progresses to mucosal patches on the oral mucosa and mucocutaneous lesions resembling the condylomata lata of secondary syphilis. Periostitis and regional lymphadenopathy are common.
- **Late manifestations:** It occur in the form of destructive gummas, osteitis, and gangosa which are more common than in late yaws.

Pinta

Pinta (also known as *mal del pinto, carate, azul, purupuru*) is the most benign of all treponemal infections, caused by *T. carateum.*

- **Epidemiology:** Pinta is limited to Central America and northern South America, where it is found rarely and only in remote villages.
- **Transmission** is by direct skin-to-skin contact.
- **Clinical manifestations:** Pinta is characterized by marked changes in skin color without causing destructive lesions. It is manifested as:
  - **Pruritic papules:** They occur as primary lesions on the extremities or face.
  - **Pintides** are disseminated secondary lesions, characterized by deeply pigmented, pruritic lesions. They are infectious and may persist for years.
  - **Dyschromic macules** are the late pigmented lesions which may contain treponemes.
  - Over time, most lesions become depigmented to form white achromic lesions

Diagnosis of Non-venereal Treponematoses

Diagnosis is based on the clinical manifestations, dark ground microscopy and serological tests.

- As they are virtually indistinguishable from *T. pallidum* antigenically, hence the serological tests used for syphilis can also be used for diagnosis of non-venereal treponematoses.
- To date, there is no test available that can differentiate between various treponemes.

TREATMENT **Non-veneral treponematoses**

Both patients and their contacts can be treated by benzathine penicillin.

BORRELIA

The ultrastructure of *Borrelia* is similar to *Treponema* and *Leptospira* with minor differences (refer to Table 37.1 and Fig. 37.1A).

- **Size:** Larger, 10–30 µm in length and 0.2–0.5 µm breadth.
- **Spirals:** They are less in number (3–10) with wider spirals (3 µm) and longer amplitude (2 µm).
- **Endoflagella:** More in number (7–11), attached subterminally at the pole.
- **Microscopy:** *Borrelia* is poorly Gram-stained (other spirochetes do not take up Gram stain). It is better viewed under dark ground microscope or by sliver impregnation staining.

Most of the species of *Borrelia* occur as commensals on the buccal and genital mucosa. Few are pathogenic to men, such as:

- *B. recurrentis* causes epidemic relapsing fever.
- *B. burgdorferi* is the agent of Lyme disease.
- *B. vincentii* causes Vincent's angina in association with fusiform bacilli.

RELAPSING FEVER

Relapsing fever (RF) is characterized by recurrent episodes of fever and nonspecific symptoms following exposure to insect vector carrying *Borrelia* species. Relapsing fever is of two types:

1. **Epidemic RF**: It is caused by *B. recurrentis* and transmitted by louse.
2. **Endemic RF** is caused by *Borrelia* species other than *B. recurrentis* such as *B. duttoni*, *B. hermsii* and *B. turicatae*. It is transmitted by tick.

Pathogenesis

- **Mode of transmission**
  - **Epidemic RF**: It is transmitted by human body louse (*Pediculus humanus*). Borreliae are introduced by crushing of the louse (e.g. by scratching) leading to deposition of insect's infected hemolymph containing numerous spirochetes on the abraded skin and mucous membranes
  - **Endemic RF:** It is transmitted by bite of an infected tick (*Ornithodoros* species).
- From the inoculated site, *Borrelia* spreads rapidly leading to bacteremia and fever. Host's immune system tries to eliminate the bacilli from the body.
- However, the borrelial surface antigens frequently undergo **antigenic variation**. Each time, new antigens are produced which can evade host's immune system leading to repeated bacteremia and recurrent febrile episodes.

TABLE 37.6: Differences between epidemic and endemic relapsing fever

Characters	Epidemic relapsing fever	Endemic relapsing fever
Agent	*B. recurrentis*	*B. duttoni, B.hermsii*
Natural host	Humans	Rodents
Transmitted by	Louse–by crushing or rubbing	Tick bite
Distribution	East Africa (Sudan and Ethiopia)	North America, Central Asia, and Africa
Hemorrhage, CNS features	More common	Less common
Treatment	Doxycycline—single-dose	Doxycycline for 1 week

Clinical Manifestations

Both epidemic and endemic RF have similar manifestations although not identical (Table 37.6). Incubation period is about 7–8 days.

- **Recurrent febrile episodes** lasting for 3–5 days occur intervening with afebrile periods of 7–9 days. Subsequent episodes are shorter.
- **Non-specific symptoms** may be present like alteration of sensorium, abdominal pain, vomiting and diarrhea.
- **Hemorrhages:** Petechiae, epistaxis and blood-tinged sputum are more likely in epidemic RF.
- **Neurologic features** such as meningitis, seizure, focal deficits, paraplegia and psychosis may occur in 10–30% of cases and are more common in epidemic RF.

Laboratory Diagnosis

- **Microscopy:** Microscopic features of *Borrelia* have been described earlier. Various methods are available to detect *Borrelia* from blood.
  - Peripheral thick or thin smear-stained by Wright- or Giemsa-stain (Fig. 37.6).
  - Direct fluorescent antibody test using monoclonal antibody is employed to identify the species.
  - Dark ground microscope (low sensitivity)
  - Quantitative buffy coat (QBC) analysis is an alternative method with higher sensitivity
  - It is poorly gram-negative.
- **Culture:** During afebrile period, microscopy fails to detect *Borrelia*; hence, the confirmation is made by isolation of *Borrelia* from blood.
- **Animal pathogenicity** testing can be done by intraperitoneal inoculation into white mice.
- **Serology**
  - **ELISA** and **IFA** (indirect fluorescence assay) are available to detect serum antibodies. Fourfold rise

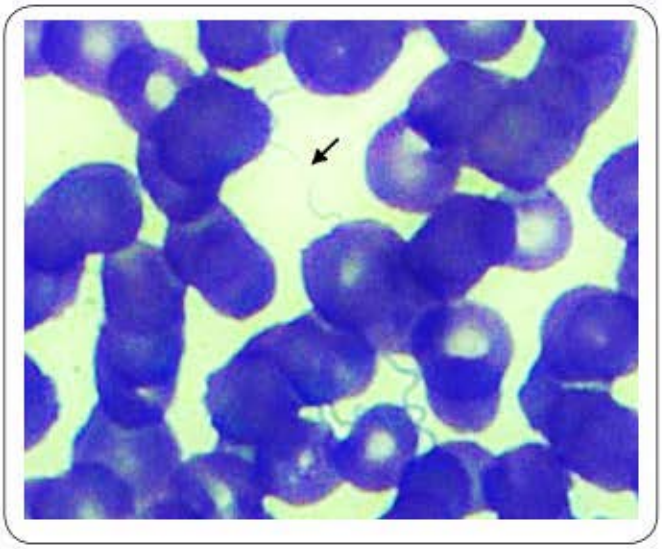

Fig. 37.6: Peripheral blood smear showing *Borrelia* species (Giemsa-staining) (arrow showing)

Source: Public Health Image Library, ID# 14495/Fort Collins/Centers for Diseases Control and Prevention (CDC), Atlanta (*with permission*)

Fig. 37.7: Erythema migrans: Annular bull's eye pattern rash

Source: Public Health Image Library, Centers for Disease Control and Prevention (CDC), Atlanta, ID# 9874/J. Gathany (*with permission*)

of titer can be considered significant. However, false positive results may occur in other spirochete infections.

- **GlpQ assay:** It is the most reliable serological method. It is an immunoblot assay detecting antibody against the recombinant GlpQ antigen (Glycerophosphodiester phosphodiesterase).

- **Molecular methods:** Multiplex Real-time PCR has been developed targeting *16S rRNA* and *GlpQ* genes to identify the various species of *Borrelia* causing RF.

TREATMENT **Relapsing fever**

Antibiotics such as doxycycline or erythromycin are the drug of choice for relapsing fever. Recommended schedule is single dose for epidemic RF, and 7–10 days course for endemic RF.

LYME DISEASE

Agent

Lyme disease or Lyme borreliosis is caused by three genomospecies of *Borrelia*, collectively referred to as *Borrelia burgdorferi* sensu lato (i.e. *B. burgdorferi* in the general sense). They are:

- *Borrelia burgdorferi* sensu stricto (*B. burgdorferi* in the strict sense, hereafter referred to as *B. burgdorferi*)
- *Borrelia garinii*
- *Borrelia afzelii.*

Epidemiology

Rodents and deer are main reservoirs of Lyme disease. It is widespread in USA, but also reported from other parts of the world.

- All three genomospecies are found in Europe
- *B. burgdorferi* is the sole cause of Lyme disease in USA.
- Latter two species; *B. garinii* and *B. afzelii* infections occur in Asia.

Transmission

Lyme disease is transmitted by **tick bite** (*Ixodes ricinus* complex). All three stages of tick, i.e. larval, nymphal, and adult stages can transmit the infection.

- The spirochete expresses outer-surface protein A (OspA) in the midgut of the tick which is required for its survival in tick.
- When the bacterium reaches the salivary gland of the tick, it expresses protein **OspC** that binds to a tick salivary-gland protein (**Salp15**). This attachment is crucial for transmission.
- The tick must attach at least for 24 hours for transmission of *B. burgdorferi.*

Clinical Manifestations

Lyme disease occurs through four stages:

- **Stage 1: Early localized infection:** After an incubation period of 3–32 days, an annular maculopapular lesion develops at the site of the tick bite called **erythema migrans**, commonly involving thigh, groin, and axilla (Fig. 37.7). It may be absent in 20% of the cases.
- **Stage 2: Early disseminated infection:** *B. burgdorferi* spreads hematogenously to many sites within days or weeks resulting in:
  - Secondary annular skin lesions
  - Musculoskeletal pain (arthralgia)
  - Profound malaise and fatigue

- Neurological abnormalities, which occur in 15% of cases and include meningitis, encephalitis and a typical lymphocytic meningoradiculitis seen in cases from Europe and Asia; called ***Bannwarth's syndrome***
- Cardiac involvement occurs in 8% of cases, including atrioventricular block.

- **Stage 3: Late persistent infection (Lyme arthritis):** About 60% of untreated patients develop frank arthritis involving *large joints* (especially the knees), lasting for weeks or months in a given joint. Some cases of Lyme arthritis are refractory for treatment. **Acrodermatitis chronica atrophicans** is a late skin manifestation caused by *B.afzelii*, (affecting elderly women).
- **Post-Lyme syndrome** (Chronic): Few patients present with chronic fatigue symptoms and neurocognitive manifestations, develop after months to years of infection.

Laboratory Diagnosis

- **Isolation** of *B. burgdorferi* can be done by culturing specimens like skin lesions, blood or CSF in special medium called BSK medium (Barbour-Stoenner-Kelly). Cultures are incubated at 34°C and examined under dark field microscope weekly for two months.
- **Genus atrophicans** is based on distinct properties of *Borrelia* such as morphology, size and motility as described earlier.
- **Molecular methods:**
  - PCR detecting specific DNA is much superior to culture for the detection of *B. burgdorferi* in joint fluid. But its sensitivity is poor for CSF, blood or urine samples.
  - PCR-RFLP (restriction fragment length polymorphism) of the intergenic *rrf-rrl* region has been used for genomospecies detection.
- **Serology (antibody detection):** The most common method of diagnosis of Lyme disease is by characteristic clinical picture with a positive serological test.
  - **ELISA and western blot** formats are available detecting IgM and IgG separately.
  - In the first month of infection, both IgM and IgG are detected. As disease proceeds, IgM disappears and IgG response predominates.
  - **Fourfold rise of antibody** at 2–3 weeks' interval is more significant which obviates the false positive results.
  - **Two-test approach:** CDC recommends to perform an ELISA first→ if found positive, it has to be confirmed by western blot.
  - **C6 peptide IgG ELISA** is recently introduced which has shown promising results. It is a second generation ELISA, uses *VlsE* lipoprotein antigen of *B. burgdorferi*.
- **↑WBC count:** Joint fluid examination reveals elevated polymorphonuclear cells whereas CSF shows lymphocytosis.

TREATMENT — Lyme disease

- For all stages of Lyme disease except CNS and CVS infection: Oral doxycycline is the drug of choice, except for children where amoxicillin is given. Duration of treatment is as follows:
  - Localized skin infection (14 days)
  - Early disseminated infection (21 days)
  - Acrodermatitis (30 days)
  - Arthritis (30–60 days)
- For CNS or CVS infection: Cefrtiaxone is given for 14–28 days.

VINCENT'S ANGINA

Vincent's angina (or trench mouth) is an acute ulcerative necrotising gingivostomatitis or oropharyngitis caused by symbiotic association of two organisms:

- *Borrelia vincentii* in association with *Leptotrichia buccalis* (formerly known as *Fusobacterium fusiforme)*: An anerobic gram-negative bacillus, long, thin spindle-shaped with pointed ends (Fig. 37.8).
- Disease is characterized by inflamed pharyngeal mucosa covered by greyish membrane resembling diphtheria, but it peels off easily.
- Both the agents are normal flora of mouth; however, they can be potential pathogens in the presence of underlying malnutrition or viral infections.

Laboratory Diagnosis

It may be made by demonstrating spirochetes and fusiform bacilli in stained smears of exudates from the lesions. Cultivation is difficult but can be done in enriched media, incubated anaerobically.

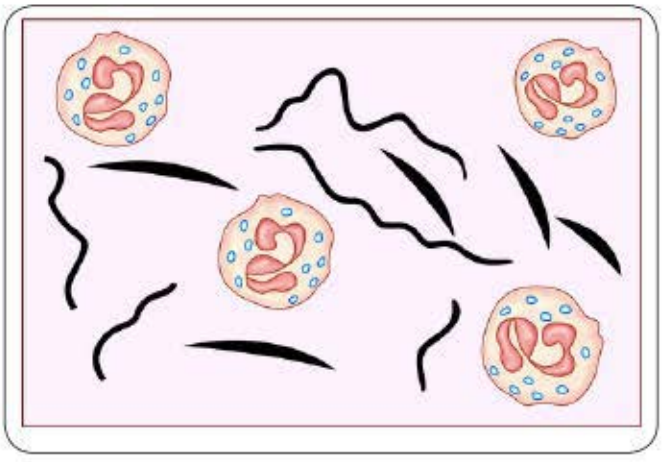

Fig. 37.8: Schematic picture showing *Borrelia vincentii* and *Leptotrichia buccalis*

TREATMENT **Vincent's angina**

Penicillin and metronidazole are effective.

LEPTOSPIRA

CLASSIFICATION

Phenotypic Classification

Species: *Leptospira*, comprises of two species:

1. L. *interrogans* (pathogenic for humans): It causes leptospirosis or Weil's disease involving liver and kidney.
2. *L. biflexa* (saprophyte).

Serovars and serogroups: *Leptospira* is antigenically complex and can be further classified on the basis of agglutination testing with specific antisera against the surface LPS (lipopolysaccharide) antigens.

- *L. interrogans* comprises of 25 serogroups (Table 37.7) which further consist of over 250 serovars.
  - Serogroup Icterohaemorrhagiae has several serovars such as Icterohaemorrhagiae, Copenhageni, Lai, Naam and Mwogolo.
  - New serogroups and serovars continue to be discovered.
  - Although all serogroups and serovars are morphologically identical, produce similar clinical picture but they differ in their geographical distribution and in severity of infection.
- *L. biflexa* has 65 serovars arranged in 38 serogroups.

Genotypic Classification

DNA hybridization, *Leptospira* has been classified into 17 genomic species. Though it is considered to be the gold standard technique for species level identification of leptospires, it is seldom used because of its complexity.

LEPTOSPIRA INTERROGANS

L. interrogans have the size of 6–12 µm length × 0.1 µm width which allows them to pass through filters used to sterilize the culture medium.

- They are tightly and regularly coiled, with characteristic hooked ends (hence the species name *interrogans*—resembling interrogation or question mark).
- Spirals have a wave length (interval between spirals) of 0.5 µm and amplitude of 0.1 µm.
- They possess a single endoflagellum attached at the pole and are highly motile exhibiting spinning and translational movements.
- They cannot be seen under the light microscope due to their thinness (leptos, meaning fine or thin). They do not take up ordinary stains.

TABLE 37.7: *Leptospira* serogroups

Serogroups of *Leptospira interrogans*		
Australis	Grippotyphosa	Sarmin
Autumnalis	Hebdomadis	Sejroe
Ballum	Icterohaemorrhagiae	Semaranga
Bataviae	Javanica	Tarassovi
Canicola	Leptonema	Hurstbridge
Celledoni	Lyme	Ranarum
Cynopteri	Mini	Turneria
Djasiman	Pomona	Manhao
	Pyogenes	

- They may be observed by dark ground or phase contrast microscope or stained by sliver impregnation method and by immunofluorescence.

Epidemiology

- **Mode of transmission:** Leptospirosis is zoonotic. Direct human-to-human transmission does not occur. It is transmitted by:
  - Indirect contact with water, moist soil and wet surfaces contaminated with animal urine or
  - Direct contact with urine and products of parturition, placenta of infected animals.
- **Source:** Although more than 100 animals can be infected; but important sources of infection are rats, dogs, cattle and pigs. Even asymptomatic animals can transmit the infection via urine.
- **Risk factors** that promote transmission include:
  - Lower socioeconomic status
  - Urban and rural slum areas
  - Rainfall and floods
  - Occupational exposure to animal urine, e.g. rice field, farmers.
- **3R's:** The three important epidemiological determinants for leptospirosis include exposure to **r**odents, **r**ainfall and **r**ice field.
- **Global distribution:** Leptospirosis is worldwide in distribution. Highest burden of the disease has been reported from area with high population density such as urban slums of Brazil, India and Thailand.
- **In India:** Leptospirosis is endemic in Tamil Nadu, Kerala and Andaman (called Andaman hemorrhagic fever); and is also being increasingly reported from other states.

Pathogenesis

There are two distinct phases of pathogenesis following leptospiral infection:

1. **First phase (septicemic phase):** After entering through the mucosa (conjunctival or oral) or abraded skin, *L. interrogans* spill over to the bloodstream and

then disseminate hematogenously to various organs including brain, liver, lung, heart and kidney.

- **Vascular damage:** Spirochetes can be found in the walls of capillaries, medium and large-sized vessels. The exact mechanism of vascular damage is not clear.
- Penetration and invasion of tissues is due to active motility and release of hyaluronidase.

2. **Second phase (immune phase):**
   - As antibodies develop, spirochetes disappear from the blood. Antigen antibody complexes are deposited in various organs.
   - Renal colonization- Bacilli become adherent to the proximal renal tubular brush border and are excreted in urine.

Clinical Manifestations

The incubation period is around 5–14 days. In general, the manifestations can be divided into two distinct clinical syndromes:

1. **Mild anicteric febrile illness:** It occurs in 90% of patients. It is biphasic; a septicemic phase occurs first, followed by immune phase.
2. **Weil's disease** (Hepato-renal-hemorrhagic syndrome): It is a severe form of icteric illness and occurs in 10% patients. *Typical biphasic course may not be present.* It is more severe and fulminant (Table 37.8).

LABORATORY DIAGNOSIS	Leptospirosis

Specimens: CSF, blood and urine

Microscopy

- Dark ground or phase contrast microscope
- Sliver impregnation staining

Contd...

Contd...

LABORATORY DIAGNOSIS	Leptospirosis

- Spirally coiled bacilli (tightly and regularly coiled), with characteristic hooked ends like umbrella handle.

Isolation

- Culture condition: 30°C for 4–6 weeks
- Medium: EMJH medium, Korthof's and Fletcher's media

Animal inoculation: Samples are inoculated into hamsters and young guinea pigs.

Serology for antibody detection

- Genus specific tests: Macroscopic slide agglutination test, latex agglutination test, ELISA, ICT
- Serovar specific test: Microscopic agglutination test

Molecular methods:

- PCR detecting I6S or 23S rRNA or IS1533 genes
- PCR-RFLP and PFGE- to detect genomospecies
- Faine's diagnostic criteria
- Nonspecific findings - altered renal and liver function tests

Laboratory Diagnosis

- **Specimens:** CSF and blood (in first 10 days of infection) and urine (between 10 and 30 days of infection) are useful specimens.
- **Microscopy:** *Leptospira* are extremely thin; hence, cannot be seen under light microscope.
  - **Wet films:** They may be observed under dark ground or phase contrast microscope (Fig. 37.9).
  - **Staining:** They do not stain by ordinary stain, but can be stained by *sliver impregnation stains* such as Fontana stain and modified Steiner technique.
  - *L. interrogans* is 6–12 µm long and 0.1 µm wide.
    - They are *tightly* and regularly coiled, with characteristic hooked ends like umbrella handle.
    - Spirals have a wave length (width) of 0.5 µm and amplitude of 0.1 µm.

TABLE 37.8: Clinical stages of leptospirosis

	Mild anicteric febrile illness		Weil's disease	
	First stage 3–10 days (septicemic)	**Second stage** 10–30 days (immune)	**First stage** 3–10 days (septicemic)	**Second stage** 10–30 days (immune)
Clinical findings	▪ Fever ▪ Myalgia ▪ Headache ▪ Conjunctival suffusion ▪ Abdominal pain ▪ Pharyngeal erythema without exudates ▪ Vomiting	▪ Meningitis, ▪ Uveitis, optic neuritis chorioretinitis ▪ Rash ▪ Fever ▪ Peripheral neuropathy	▪ High-grade fever ▪ Liver-jaundice and raised liver enzymes ▪ Hemorrhages: • Pulmonary hemorrhage • Petechiae and purpura • Conjunctival hemorrhage, • Gastrointestinal hemorrhage ▪ Kidney—Raised serum urea and creatinine and renal failure

Source: Public Health Image Library, ID# 1220/ NCID/ Rob Weyant/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- They are highly motile; exhibit spinning and translational movements.
- **Disadvantage:** Microscopy is less sensitive and requires technical expertise. Serum proteins and fibrin strands in blood may resemble similar to leptospires.

- **Isolation**
  - **Culture condition:** *Leptospira* is obligate aerobe and slow growing. Cultures should be incubated at 30°C for 4–6 weeks at pH 7.2–7.5. Culture fluid should be examined under dark ground microscope for the presence of leptospires on the first, third and fifth day followed by weekly intervals up to 6 weeks.
  - **Culture media:** As *Leptospira* is highly fastidious, requires enriched media such as:
    - **EMJH medium** (Ellinghausen, McCullough, Johnson, Harris) is a semisynthetic liquid medium, most commonly used nowadays.
    - It is composed of albumin fatty acid supplement added to the basal media containing 0.1% agar. Leptospiral growth produces a dense ring of organisms just at the undersurface of the medium, called **Dinger's ring**.
    - **Korthof's** media with rabbit blood and **Fletcher's** semisolid media can be used.
  - **Advantages**
    - Isolation of *Leptospira* confirms the diagnosis.
    - It is useful to maintain the stock culture of the *Leptospira* in the laboratories.
  - **Disadvantages**
    - Culture technique is laborious, technically demanding and time-consuming.
    - False-positive results: These may occur due to contamination of culture media with other organisms or saprophytic leptospires.
    - False-negative results: These may occur due to prior use of antibiotics, or incubating in improper temperature and pH.
  - **Precautions taken** for obtaining pure culture:
    - Subculture in media containing antibiotics such as 5-fluorouracil which inhibits the contaminants.
    - Filtration of urine sample through 0.22 µm filter and followed by inoculation on to selective culture media.
    - Urine should be collected in phosphate buffer saline (PBS) with pH 7.2 to neutralize the acidic pH of urine.
- **Animal inoculation:** Samples may be inoculated into animals such as hamsters (4–6 weeks old) and young guinea pigs and peritoneal fluid is examined for presence of leptospires.
- **Serology for antibody detection:**
  - IgM antibodies appear early within one week of illness, reach peak levels in third or fourth week and then decline slowly and become undetectable within six months.
  - IgG antibodies appear later than IgM; reach peak level after few weeks of illness and may persist at low level for years.

  Antibody detection tests can be broadly classified into:
  - **Genus-specific tests** uses broadly reactive genus-specific antigen prepared from nonpathogenic *L. biflexa* Patoc 1 strain. They cannot detect the infecting serovar. Various tests available are:
    - Macroscopic slide agglutination test.
    - Microcapsule agglutination test (MCAT)
    - Latex agglutination test.
    - ELISA: It detects IgM and IgG separately.
    - Lepto dipstick assay: It detects IgM antibodies.
    - Immunochromatographic test (ICT): It detects IgM antibodies.
  - **Serovar-specific test:** Microscopic agglutination test (MAT) detects antibodies against specific serovars of *L. interrogans*. It is the gold standard method and the reference test for the diagnosis of leptospirosis.
- **Cross agglutination and absorption test (CAAT)** is done to detect the relatedness between the strains.
- **Molecular methods:** PCR has been found particularly useful in severe disease, before seroconversion occurs.
  - Various genes such as 16S or 23S rRNA or IS1533 insertion sequence are targeted.
  - However, PCR is not serovar-specific.
  - PCR-RFLP (Restriction fragment length polymorphism) or PFGE (Pulsed-field gel electrophoresis) are the methods followed to determine the genomo species of *Leptospira*.
- **Faine's criteria:** It is a WHO-approved guideline used for the diagnosis of leptospirosis. It is based on clinical, epidemiological and laboratory findings.

- **Non-specific findings** such as:
  - **Altered renal function:** Elevated levels of blood urea nitrogen and serum creatinine.
  - **Altered liver function:** Elevated bilirubin and liver enzymes in serum.
  - Urine sediment analysis may show increased leukocytes, erythrocytes, hyaline and granular casts.

TREATMENT **Leptospirosis**

- **Mild leptospirosis** should be treated with oral doxycycline (100 mg twice a day for 7 days). Amoxicillin can be given alternatively.
- **Severe leptospirosis:** Penicillin is the drug of choice (1.5 million units IM, four times a day for 7 days), alternatives being ceftriaxone or cefotaxime.

Prevention

Though several trials are ongoing, but no vaccine is approved for human leptospirosis yet.

Control Measures Include

- Chemoprophylaxis with doxycycline is recommended for anticipated short-term exposures, such as military training or travelling or fresh-water swimming.
- General sanitation approaches including proper waste disposal.
- Rodent control.
- Avoidance of swimming in contaminated places.
- Health education.

EXPECTED QUESTIONS

I. Essays:

1. Describe the clinical manifestations and laboratory diagnosis of syphilis.
2. Kishan, a young farmer was complaining of fever, headache, and myalgia. Gradually, he developed yellow discoloration of skin and sclera. On examination, he had conjunctival inflammation and hepatosplenomegaly. His blood count showed neutrophilia with a thrombocytopenia. Liver function tests showed an elevated conjugated bilirubin with mild elevation of transaminases. He was also found to be oliguric and uremic.
   a. What is the etiological agent and how is this disease transmitted?
   b. What is the typical clinical presentation and pathogenesis of this condition?
   c. How will you confirm the diagnosis?

II. Write short notes on:

1. Relapsing fever
2. Lyme's disease
3. Yaws

III. Multiple Choice Questions (MCQs):

1. **Which of the following tests confirms the diagnosis of leptospirosis?**
   a. Culture of urine on EMJH media.
   b. Testing serum by darkfield examination for the presence of leptospires.
   c. Testing acute and convalescent phase sera for anti-leptospiral antibodies by microscopic agglutination test.
   d. Culture of CSF on blood and chocolate agar.
2. **Which of the following statements about relapsing fever is correct?**
   a. Each relapse is associated with an antigenically distinct variant.
   b. Blood smears should be made when the patient is afebrile.
   c. Transmitted by flea bite.
   d. Caused by *Borrelia burgdorferi.*
3. **Weil's disease is caused by:**
   a. *Leptospira interrogans*
   b. *Borrelia recurrentis*
   c. *Treponema carateum*
   d. *Treponema pallidum*
4. **Bejel is caused by:**
   a. *Borrelia recurrentis*
   b. *Treponema endemicum*
   c. *Treponema pallidum*
   d. *Treponema carateum*

CHAPTER 38

Rickettsiae, Coxiella, Bartonella

Chapter Preview

- General properties
- Family rickettsiaceae
  - Rickettsia species
  - Orientia tsutsugamushi
- Family anaplasmataceae- Ehrlichia, and others
- Former members
  - Coxiella burnetii
  - Bartonella species

GENERAL PROPERTIES

Rickettsiae comprise of group of small non-motile gram-negative coccobacilli that possess the following common characteristics:

- They are obligate intracellular organisms.
- They are not cultivable in artificial media, although they can grow in cell lines, or by animal and egg inoculation.
- They are transmitted by an arthropod vector, such as tick, mite, flea or louse.

Classification

The order Rickettsiales has two families:

1. Family Rickettsiaceae comprises of two pathogenic genera—*Rickettsia* and *Orientia*.
2. Family Anaplasmataceae includes four genera—*Ehrlichia, Wolbachia, Anaplasma* and *Neorickettsia*.

Former members such as *Coxiella* and *Bartonella* are now excluded from the family because:

- *Coxiella* is not arthropod borne; infection is transmitted by inhalational mode.
- *Bartonella* is not an obligate intracellular parasite; capable of growing in cell-free media. It also differs in genetic properties.

Rickettsiae Versus Viruses

Because of the small size and obligate intracellular properties, Rickettsiae were once thought to be viruses, however now they are confirmed to be bacteria due to having following characters:

- They possess gram-negative cell wall (however, they are poorly gram-stained, better stained with Giemsa or Gimenez stains).
- They contain both DNA and RNA.
- They possess ribosomes for protein synthesis and enzymes for the Krebs cycle.
- Rickettsiae multiply by binary fission.
- They are susceptible to antibacterial agents.
- Rickettsiae are large enough to be seen under the light microscope.
- They are held back by bacterial filters.

History

- *Rickettsia* is named after Howard Taylor Ricketts (1911) who had isolated *Rickettsia rickettsiae*.
- *Rickettsia prowazekii* is named by Da Rocha Lima in honor of von Prowazek.
- Both von Prowazek and H Ricketts died of typhus which they contracted during their study.
- Charles Nicolle identified the role of body lice in the transmission of epidemic typhus.

FAMILY RICKETTSIACEAE

Family Rickettsiaceae comprises of two pathogenic genera *Rickettsia* and *Orientia* (Table 38.1).

GENUS RICKETTSIA

Species of *Rickettsia* can be categorized into two groups based on the clinical manifestations (Table 38.1):

1. Typhus group
2. Spotted fever group

Antigenic Structure

The cell wall of rickettsiae is similar to any gram-negative bacteria, composed of peptidoglycan, lipopolysaccharide, and an outer membrane containing few outer membrane proteins.

TABLE 38.1: Features of Rickettsiaceae

Broad group	Species	Disease	Vector	Distribution	Rash	Eschar	LN	Weil-Felix test
Typhus group	*R. prowazekii*	Epidemic typhus	Louse (rubbing)	Worldwide (Africa and South America)	80% (All over the body except palm and sole)	–	–	OX19 ++++ OX2 +/-
		Brill–zinsser disease						Negative or weakly positive
	R. typhi	Endemic typhus	Flea	Worldwide	80% (trunk)	–	–	OX19 ++++ OX2 +/-
Spotted fever group	*R. rickettsii*	Rocky mountain spotted fever (RMSF)	Tick	America	90% (extremities and trunk, more hemorrhagic)	<1%	+	OX19 ++ OX2 ++
	R. conorii	Indian tick typhus (ITT)	Tick	Europe, Asia	97%	50%	+	
	R. africae	African tick bite fever	Tick	Sub-Saharan Africa	50% (vesicular)	90%	++++	
	R. akari	Rickettsialpox	Mite (gamasid)	USA, Ukraine, Turkey, Mexico	100% (vesicular)	90%	+++	All negative
Scrub typhus	*Orientia tsutsugamushi*	Scrub typhus	Mite (trombiculid)	Asia, Australia	50%	35%	+++	OXK +++

- **Species specific outer membrane proteins (OMP):** They are highly immunogenic surface cell antigens (*sca*), induce the synthesis of protective antibodies, thus can be used for vaccine as well as for diagnosis.
  - OmpA is present only in spotted fever group of rickettsiae (coded by sca5 gene).
  - OmpB is present in both spotted fever group and typhus fever group rickettsiae (coded by sca4 gene).
- **Group specific alkali stable lipopolysaccharide (LPS) antigen:** It is found in some rickettsiae and is shared by certain strains of *Proteus* (OX19, OX2 and OXK strains). This antigenic cross reactivity serves as the basis of Weil-Felix reaction, the widely used serological test for the diagnosis of rickettsial infections.

Pathogenesis

- **Transmission:** All rickettsiae are transmitted to humans by arthropod vectors (Table 38.1).
  - **Tick and mite** borne rickettsiae are transmitted by biting, which leads to inoculation of organisms present in arthropod's saliva into the skin of the host during its blood meal.
  - **Louse and flea** borne rickettsiae are transmitted by—
    - Autoinoculation following rubbing or scratching of abraded skin or mucosa contaminated by insect feces (seen in epidemic and endemic typhus), or
    - Aerosol (by inhaling dried louse or flea feces in the laboratory or as part of bioterrorism).
  - **Transovarial transmission:** Tick and mite can act as reservoir, maintain the organism, and pass to their offspring. Hence, they can serve as both vector as well as reservoir.
- **Spread:** Rickettsiae spread through the lymphatics from the portal of entry, multiply in the regional lymph nodes and then spread via bloodstream.
- **Target sites:** For all rickettsiae, the final target site is the endothelial cells (in addition, *R. akari* and *O. tsutsugamushi*, attack the monocytes).
- **Phagocytosis:** Adhesion to the endothelial cells is mediated by outer membrane proteins; OmpA and OmpB present on rickettsial surface. Following adhesion, the organisms are phagocytosed.
- **Intracellular locations:** Following phagocytosis, rickettsiae remain inside a vacuole. Later on, they vary in their intracellular locations:
  - *Rickettsia* and *Orientia* produce phospholipase A that lyses the vacuoles. They come out and are found free in the cytoplasm (in addition, the spotted fever rickettsiae are also found free in the nucleus).
  - *Coxiella* and *Ehrlichia* continue to multiply in cytoplasmic vacuoles.
    - *Coxiella* vacuole fuses with lysosome, but it is able to survive inside the acidic environment of the phagolysosome.
    - In contrast, the ehrlichiae are maintained inside the vacuoles. They are killed if they fuse with the lysosomes.

- **Multiplication:** Inside the host cells, they multiply slowly by binary fission (generation time is about 9–12 hours).
- **Cell-to-cell spread:** Spotted fever rickettsiae can spread from cell-to-cell by actin polymerization. In contrast other rickettsiae accumulate in the cell until the lysis of the cell takes place.
- **Reason for obligate intracellular survival:** It is not understood. However, it is observed that rickettsiae depend on the host cell for many reasons—
  - They lack many enzymes required for glycolysis, pentose phosphate pathways, purine and pyrimidine synthesis pathways and also lack genes coding for several amino acids.
  - Although, they can produce their own adenosine triphosphate (ATP), but prefer to use the host cell ATP if available.
- **Endothelial cell injury:** This occurs via lipid peroxidation of host-cell membranes.
  - In order to exploit the cell for its own growth, rickettsiae inhibit cell apoptosis by up regulating NF-*k*β pathway activation.
  - The vascular endothelial cells enlarge, degenerate and cause thrombosis of the vessels leading to rupture and necrosis.
- **Release:** Once these bacteria are released from the host cells, they are unstable and die quickly. The exception is *Coxiella* which is highly resistant to desiccation and remains viable in the environment for months to years.

Epidemic Typhus (Louse-borne)

Epidemic typhus is caused by infection with *R. prowazekii.*

- **Vector:** Human body louse, *Pediculus humanus corporis* acquires the organism while taking the blood meal from an infected patient. Rickettsiae multiply in the midgut epithelial cells of the louse and are shed in its feces.
- **Mode of transmission:** (1) Autoinoculation of the organisms following rubbing or scratching of abraded skin or mucosa contaminated by louse feces, (2) rarely, by inhalation of louse feces, in the laboratory or during bioterrorism.
- **Clinical manifestations:** Epidemic typhus is an acute febrile disease; accompanied by headache, myalgia, eye discharge and rashes occurring after an incubation period of 1–2 weeks.
  - **Rash** begins on the upper trunk, usually on the fifth day, and then becomes generalized, involving the entire body except the face, palms and soles.
  - **Myalgia** is usually severe, was referred to as sutama ("crouching") in Burundi outbreak, a designation reflecting the posture of the patients attempting to alleviate the pain.
  - **Complications** include interstitial pneumonitis, CNS involvement like mental confusion and coma ('*typhus*' name comes from the Greek word *typhos* meaning smoky or hazy, describing the state of mind of the affected patients), myocarditis and acute renal failure.
- **Risk factors:** Outbreaks occur when louse population increases; especially in unhygienic conditions. Typical settings include refugee camps, prisons and overcrowded communities.
- **Zoonotic cycle:** Eastern flying squirrels (*Glaucomys volans*) and their lice and fleas maintain *R. prowazekii* in the environment.
- **Geographical distribution:** It is endemic in Africa (notably Burundi, Rwanda and Ethiopia) and South America (Peru, Bolivia and Ecuador). Burundi outbreak in 1997 had involved nearly 1 Lakh people in refugee camps. No cases have been reported from South East Asia since 1978 and Western Pacific since 1969.
- **Brill–zinsser disease:** It is a recrudescent illness occurring years after acute epidemic typhus. *R. prowazekii* remains latent for years; its reactivation occurs due to waning immunity, which leads to sporadic infection or outbreaks.

Endemic Typhus (Flea-borne)

Endemic (murine) typhus is caused by *R. typhi* infection.

- **Vectors:** The vector for endemic typhus is rat flea (*Xenopsylla cheopis*) or rarely by cat flea (*Ctenocephalides felis*).
- **Mode of transmission:** It is transmitted by inoculation on skin or inhalation of flea's dried feces, less frequently by the flea bite.
- **Reservoir:** Rodents such as *Rattus rattus* and *R. norvegicus* species are the natural reservoirs; whereas the opossum/cat flea (*C. felis*) cycle is prominent in southern Texas and southern California.
- **Clinical manifestations:** Incubation period is 1–2 weeks (average 11 days).
  - Symptoms are similar to epidemic typhus but milder and rarely fatal.
  - Common symptoms include fever, headache, myalgia, anorexia and rash (involving the trunk more often than the extremities).
- **Geographical distribution:** It is endemic worldwide, especially in warm (often coastal) areas throughout the tropics having high rat infestations.
  - Recent days, it is increasingly reported from South East Asia and Western Pacific.
  - **India:** It has been reported from many places, such as Shimla, Kashmir, Mumbai, Jabalpur, Lucknow and Pune.

Rocky Mountain Spotted Fever (RMSF)

Rocky mountain spotted fever (RMSF) is caused by *Rickettsia rickettsii.*

- **Vector:** It is transmitted by various genera of ticks, such as—
  - *Dermacentor andersoni* in USA
  - *Amblyomma cajennense* in Central/South America
  - *Rhipicephalus sanguineus* in Mexico, Arizona and Brazil.
- **Transmission:** By the bite of an infected tick.
- **Reservoir:** Ticks serve as vector as well as reservoir. Other mammals like dogs, small rodents can also act as reservoir.
- **Clinical manifestations:** Incubation period ranges from 4 days to 14 days.
  - RMS fever is an acute potentially fatal disease characterized by fever, headache and rash and frequently myalgia and anorexia.
  - Rashes appear typically on extremities (wrist and ankles) and trunk. Initially they are maculopapular, later on become hemorrhagic (Fig. 38.1).
  - **Complications:** They appear late, include: vascular damage, increased permeability, edema, hemorrhage, disseminated intravascular coagulation, interstitial pneumonitis (central nervous system) CNS involvement, myocarditis and renal failure.
  - It is the most fatal rickettsial disease and is associated with higher mortality rate.
- **Geographical distribution:**
  - RMS fever is endemic in high tick population areas of USA, Central and South America.
  - It is more common during tick season (summer in tropics) and among children and males.

Fig. 38.1: Characteristic rash seen in Rocky mountain spotted fever

Source: Public Health Image Library, ID#:14489/Centers for Disease Control and Prevention (CDC), Atlanta *(with permission)*

Indian Tick Typhus (ITT)

Indian tick typhus is caused by *Rickettsia conorii.*

- **Vector:** Transmitted by tick bite (*Rhipicephalus sanguineus*).
- **Clinical manifestations:** They are similar to that of RMS fever. In addition, an eschar is observed at the site of the tick bite in 50% of cases. Disease is more severe in patients with diabetes, alcoholism, or heart failure.
- **Geographical distribution:** *R. conorii* is prevalent in southern Europe, Africa and southern Asia.
  - Apart from ITT, disease caused by *R. conorii* has been given various other regional names such as—
    - Mediterranean spotted fever
    - Kenya tick typhus
    - Israeli spotted fever
    - Astrakhan spotted fever.
  - In India, ITT is widespread. Cases have been reported from Nagpur, Jabalpur, Sagar, Pune, Lucknow, Bangalore and Secunderabad.

Other Tick-borne Fever

- **African tick-bite fever:** It is caused by *R. africae,* transmitted by tick bite (*Amblyomma hebraeum*) and is endemic in sub-Saharan Africa.
- **Maculatum disease:** It is caused by *R. parkeri,* transmitted by tick bite (*Amblyomma maculatum*), seen in USA and South America.
- **Japanese spotted fever:** It is caused by *R. japonica,* occurs in Japan and Korea.
- **Queensland tick typhus:** It is due to *R. australis,* transmitted by Tick (*Ixodes holocyclus*).
- **Flinders Island spotted fever:** It is caused by *R. honei.*

Rickettsialpox

Rickettsialpox is caused by *Rickettsia akari.*

- **Vector:** Transmitted by bite of infected mites (*Liponyssoides sanguineus*) that are found on the surface of mice. Mites maintain the organisms by transovarian transmission.
- **Reservoir:** Mice (*Mus musculus*) are the principal reservoir of *R. akari.*
- **Clinical manifestations** of rickettsialpox are similar to any other rickettsial diseases, but differ from the later by the presence of:
  - Vesicular rashes (often confused for the rashes of chickenpox, hence so named)
  - Eschar (painless black crusted lesions surrounded by an erythematous halo), is present at the site of mite bite
  - Regional lymphadenopathy.
- **Geographical distribution:** *R. akari* is endemic in USA, Ukraine, Turkey and Mexico.

GENUS ORIENTIA

Scrub Typhus

Scrub typhus is caused by *Orientia tsutsugamushi* (formerly classified under *Rickettsia*). It differs from *Rickettsia* by both genetically as well as cell wall composition (i.e. it lacks lipopolysaccharide layer).

- **Vector:** It is transmitted by the bite of infected trombiculid mites of genus *Leptotrombidium (L. akamushi* in Japan and *L. deliensis* in India).
  - Chiggerosis: Among all stages of mite, the larvae (called **chiggers**) are the only stage that feed on humans. Hence, scrub typhus is also called *chiggerosis.*
  - Mites can maintain the organisms through transovarian transmission.
- **Clinical manifestations:** The classic presentation of scrub typhus consists of triad of an eschar (at the site of bite), regional lymphadenopathy and maculopapular rash. However, it is seen only in 40–50% of cases.
  - Non-specific manifestations may appear early, such as fever, headache, myalgia, cough, and gastrointestinal symptoms.
  - Complications, such as encephalitis and interstitial pneumonia due to vascular injury may occur rarely in the late stage.
- **Antigenic diversity:** Three major antigenic types have been identified—Karp, Gilliam and Kato. Because of this remarkable antigenic diversity exhibited by the organism, immunity wanes over 1–3 years.
- **Epidemiology:** Among the rickettsial diseases, scrub typhus is most widespread.
  - **Zoonotic tetrad:** Four elements are essential to maintain *O. tsutsugamushi* in nature—
    1. Trombiculid mites
    2. Small mammals (e.g. field mice, rats, shrews)
    3. Secondary scrub vegetations or forests (hence named as scrub typhus).
    4. Wet season (when mites lay eggs).
  - **World scenario:** Scrub typhus is prevalent in Japan, China, Philippines, and South-East Asia, including India, Pakistan, Afghanistan, tropical Australia, New Guinea, and Pacific Islands.
  - **Indian scenario:** Scrub typhus has been found since ages. Epidemics have been reported from Assam and West Bengal during the Second World War. Currently it is widespread in many parts of India, including in Puducherry.

FAMILY ANAPLASMATACEAE

EHRLICHIOSIS

Family Anaplasmataceae comprises of four obligatory intracellular organisms named *Ehrlichia, Wolbachia, Anaplasma* and *Neorickettsia* (Table 38.2).

- They reside in vertebrate reservoirs and target vacuoles of hematopoietic cells.
- Few of them are pathogenic, such as—
  - *Ehrlichia chaffeensis:* It is the agent of human monocytic ehrlichiosis, infects predominantly mononuclear phagocytes.
  - *Ehrlichia ewingii:* It infects neutrophils and causes Human granulocytic ehrlichiosis.
  - *Anaplasma phagocytophilum:* It infects neutrophils; causes Human granulocytic anaplasmosis.
  - *Neorickettsia sennetsu* infects the lymphocytes and cause mononucleosis like syndrome called Human lymphocytic ehrlichiosis.
- **Clinical feature:** They produce an acute febrile disease that is generally characterized by headache, myalgia, arthralgia, cough, pharyngitis, lymphadenopathy, diarrhea, nausea, vomiting, abdominal pain and changes in mental status.

TABLE 38.2: Features of family Anaplasmataceae

Characteristics	*Ehrlichia chaffeensis*	*Ehrlichia ewingii*	*Anaplasma phagocytophilum*	*Neorickettsia sennetsu*
Causes	Human monocytic ehrlichiosis (HME)	Human granulocytic ehrlichiosis (HGE)	Human granulocytic anaplasmosis (HGA)	Human lymphocytic ehrlichiosis (HLE)
Features	▪ Leukopenia ▪ Thrombocytopenia ▪ Elevated liver enzymes ▪ Risk factor: Immunocompromised patients	▪ Features similar to HME but less severe ▪ Risk factor: Immunocompromized patients	▪ Leucopenia ▪ Thrombocytopenia	Mononucleosis like illness Atypical lymphocytosis Lymphadenopathy
Transmitted by	Tick (*Amblyomma americanum*)	Tick (*Amblyomma americanum*)	Tick (*Ixodes scapularis*)	Ingestion of fish carrying infected flukes
Reservoir	White-tailed deer (rarely dogs)	White-tailed deer and dogs	Mice, squirrels, and white-tailed deer	Not known
Distribution	USA	USA	USA	Japan and Malaysia

- **Inclusions:** They reside inside the phagosome, multiply to produce the following three stages of growth—elementary body, initial body, and mulberry like inclusions called Morula.
- **Morulae** in neutrophil can be detected in 20–75% of cases by Giemsa-stained peripheral blood film examination.
- **Treatment:** Drug of choice for ehrlichiosis is doxycycline.

LABORATORY DIAGNOSIS	Rickettsial infections

Serology (antibody detection)

- Non-specific test (**Weil Felix test**)—Rickettsial antibodies detected against *Proteus* OX 19, OX 2 and OX K antigens
  - In epidemic and endemic typhus- ↑ OX 19 antibody
  - In tickborne spotted fever-↑OX 19 and ↑OX 2 antibodies
  - In scrub typhus- ↑OX K antibody
- Specific antibody detection – by Indirect IF, CFT ELISA and latex agglutination test

Histopathological examination

Isolation- by inoculating into cell lines (Vero, WI-38, HeLa), egg (yolk sac), or animal (guinea pig)

Neil Mooser reaction- intraperitoneal inoculation into Guinea pig, leads to testicular inflammation (positive tunica reaction)- Shown by *R.conori*, *R. akari* and *R. typhi*

PCR- detecting 16S rRNA or Omp genes

Laboratory Diagnosis of Rickettsiosis

Serology

Serology (antibody detection) is the mainstay of diagnosis of rickettsial diseases. They can be categorized into non-specific test (Weil–Felix test) and specific tests.

Weil–Felix Test

It is heterophile agglutination test works on the principle of antigenic cross reactivity.

- Group specific alkali stable lipopolysaccharide (LPS) antigen found in some rickettsiae is also shared by certain strains of *Proteus* (OX19, OX2 and OXK strains). Hence, rickettsial antibodies are detected by using *Proteus* antigens.
- **Procedure:** It is a tube agglutination test; serial dilutions of patient's serum are treated with non-motile strains of *P. vulgaris* OX19 and OX2 and *P. mirabilis* OXK.
- **Results:**
  - In epidemic and endemic typhus—sera agglutinate mainly with OX19 and sometimes with OX2
  - In tickborne spotted fever—antibodies to both OX19 and OX2 are elevated
  - In scrub typhus—antibodies to OXK are raised
  - The test is negative in rickettsialpox, Q fever, ehrlichiosis and bartonellosis.
- **False-positive titer** may be seen in presence of underlying *Proteus* infection. Hence, fourfold rise of antibody titer in paired sera is more meaningful than a single high titer.
- **False-negative result** may occur due to excess antibodies in patient's sera (prozone phenomena). This can be obviated by testing with serial dilutions of patient's sera.
- Weil–Felix test being a non-specific test should always be confirmed by specific tests.

Specific Antibody Detection Tests

- **Indirect immunofluorescence assay:** It is the most common serologic test used for confirmation of the rickettsial diagnosis.
  - Antibodies appear only after 7–10 days of infection
  - Titer of ≥1:64 is considered as significant
  - The sensitivity and specificity of immunofluorescent antibody (IFA) are 94–100% and 100% respectively.
- **Complement fixation test:** It is less sensitive than (immunofluorescent antibody reaction) IFA or ELISA but very specific.
- **ELISA** (IgM capture ELISA): It is useful in early diagnosis (<1week) with excellent sensitivity and specificity.
- **Latex agglutination test** can also be used.

Other Methods of Diagnosis

- **Histological examination** of a cutaneous biopsy sample from a rash lesion can be done even during acute illness.
- **Isolation:** Rickettsiae cannot be cultivated in cell free media.
  - However, isolation can be done by cell lines (Vero, primary chick embryo, WI-38, HeLa), egg (yolk sac inoculation), or animal inoculation (guinea pig)
  - As rickettsiae are highly infectious, isolation should be attempted cautiously only in laboratories equipped with biosafety level III facilities.
- **Neil-Mooser reaction:** Specimen is inoculated intraperitoneally into male guinea pigs. The changes observed in the animal (over 3–4 weeks), varies among various rickettsial species.
  - *R. rickettsii*—produces scrotal necrosis
  - *R. prowazekii*—produces only fever without any testicular inflammation
  - *R. typhi, R. conori* and *R. akari*—produce fever and positive tunica reaction (testicular inflammation).
- **Polymerase chain reaction (PCR):** It is available targeting 16S rRNA gene or OMP genes of various rickettsial species from peripheral blood.

TREATMENT	Rickettsiosis

Doxycycline is the drug of choice for treatment of most rickettsial illnesses. It is given as 100 mg twice a day orally for 1–5 days. Chloramphenicol is used as alternative.

Prevention of Rickettsiosis

Preventive measures include—

- Vector control strategies such as use of insecticides
- Control of rodents and other animals
- Improvement of personal hygiene.

No vaccine is available at present against rickettsial infections.

FORMER MEMBERS

Coxiella and *Bartonella* were previously under order Rickerttsiales, but now are separted.

COXIELLA BURNETII (Q FEVER)

Coxiella burnetii is an obligate intracellular organism that causes **'Q fever'**.

History

- For long time, the causative agent of the disease was unknown, hence was referred to as 'Query' or Q fever (by Edward Derrick). Later on, the agent was identified as *Coxiella burnetii*.
- *Coxiella burnetii* (formerly named as *Rickettsia diaporica)* was named after the two scientists Cox and Burnet who have contributed to its discovery.

Source of Infection

Q fever is a zoonosis. The primary sources of human infection are infected cattle, sheep and goats. Wild animals and ticks are the reservoirs of infection.

Mode of Transmission

- The most common mode is by inhalation of infected dust from soil, previously contaminated by urine and feces of diseased animals.
- By ingestion of contaminated milk.
- Rarely, transplacental, blood transfusion or through skin abrasions/mucosa.

Geographical Distribution

Q fever is endemic in most parts of the world except New Zealand and Antarctica.

- In India, it is present in human and animal population in Rajasthan, Punjab, Haryana and Delhi
- In Rajasthan, the overall prevalence rate was found to be 18.6% in humans and 24.7% in animals.

Pathogenesis

C. burnetii escapes intracellular killing in macrophages by:

- Inhibiting the final phagosome maturation step (cathepsin fusion).
- Resistant to the acidic environment of phagolysosome by producing superoxide dismutase.

Infection with *C. burnetii* induces autoantibodies, particularly to cardiac and smooth muscles.

Clinical Manifestations

- **Acute Q fever:** After an incubation period of 3–30 days, patients present with hepatitis, interstitial pneumonia, fever, CNS involvement and pericarditis or myocarditis.
- **Post Q fever fatigue syndrome:** It can occur following acute stage. Profound myalgia, headache, sweating, arthralgia, muscle fasciculation are the chief complaints.
- **Latency:** *Coxiella* may remain latent in the tissues of patients for 2–3 years.
- **Chronic Q fever:** It is characterized by endocarditis and usually occurs in patients underlying valvular heart disease, or immunosuppression. Fever is usually absent or of low grade.

Phase (Antigenic) Variation

Surface antigens, e.g. lipopolysaccharide (LPS) of *C. burnetii* shows phase variation.

- Fresh isolates possess Phase I antigen (LPS with a complex carbohydrate which blocks antibody interaction with surface proteins).
- On repeated passage in yolk sac, it switches over to Phase II (LPS is modified exposing the surface proteins that can react with antibodies).

Laboratory Diagnosis

C. burnetii is a small pleomorphic gram-negative coccobacillus. It is extremely fastidious, does not grow on routine media (it is one of the etiological agent for culture negative endocarditis). It is highly infectious, hence processing should be done in a biosafety level 3 laboratory.

- **Isolation in animals:** Blood, tissues (from cardiac valve) or milk (from infected animals) can be inoculated intraperitoneally into animals, such as hamsters (best), guinea pigs or mice.
- **Isolation in cell culture:** It can be done using human embryonic lung fibroblast cell lines.
- **Antibody detection:** Serology is the most commonly used diagnostic tool.
  - **Indirect immunofluorescence assay** (IFA) is sensitive, specific and is the method of choice.
    - In chronic infections, the antibodies to phase I antigens are elevated, whereas in acute Q fever, there is a rise of antibodies to phase II antigens
    - IgM appears in 7–10 days of infection followed by IgG, which appears after 14–20 days of infection.
  - Complement fixation test can also be done detecting IgG antibodies to phase II antigens.
  - Q fever sera do not cross-react with rickettsiae or *Proteus*.
- **Molecular methods:** Strains of *C. burnetii* differ in their plasmids which they carry. QpH1 plasmids are found in acute Q fever isolates; whereas QpRS plasmids

are found on the strains isolated from endocarditis patients.

TREATMENT Q fever

- **Acute Q fever:** Doxycycline (100 mg twice daily for 14 days) is the drug of choice. Quinolones are also effective.
- **Chronic Q fever:** Hydroxychloroquine is added to alkalinize the phagolysosome and to render doxycycline bactericidal against the organism.

Prevention

Control measures include:

- **Vaccine:** Inactivated whole-cell vaccine (Q-Vax) is licensed in Australia. It is recommended for occupationally exposed workers.
- Good animal husbandry practices should be followed such as proper disposal of animal excreta and aborted materials, isolation of aborting animals for 14 days.
- Pasteurization of milk should be done by Flash method as *C. burnetii* survives Holder's method of pasteurization.

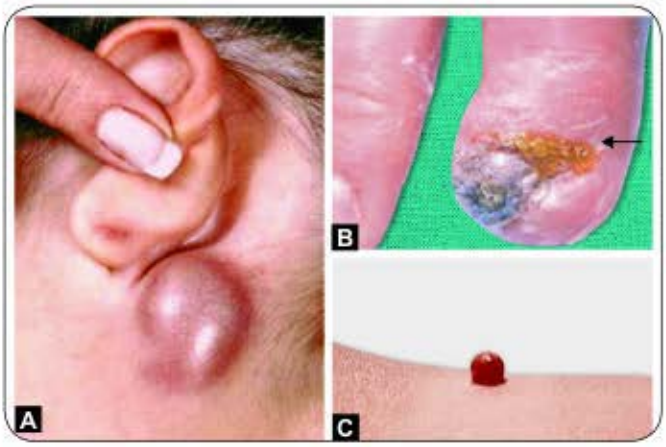
BARTONELLA

Bartonella species are fastidious, facultative intracellular, slow-growing, gram-negative bacteria that have ability to invade mammalian cells and RBCs. Among the 13 species infecting humans, three are most commonly identified pathogens—*B. bacilliformis*, *B. quintana*, and *B. henselae* (Table 38.3).

Bartonella henselae

Bartonella henselae is transmitted by cat scratch or bite. Cat fleas (*Ctenocephalides felis*) may be responsible for cat-to-cat (but not cat-to-man) transmission. It causes various diseases such as:

- **Cat-scratch disease (CSD):** Apart from *B. henselae* (most common cause), rare cases of CSD have also been associated with *Afipia felis* and *B. quintana*. It has two clinical forms:
  1. **Typical CSD:** This is more common form, characterized by sub acute regional lymphadenopathy (most common being axillary/epitrochlear lymph nodes) and painless erythematous papule or pustule, that develops at the site of cat scratch (Fig. 38.2A).
  2. **Atypical CSD:** It is characterized by extra nodal manifestations such as hepatitis, splenitis, and retinitis
- **Bacillary angiomatosis (epithelioid angiomatosis):** It is an angioproliferative disorder, characterized by neovascular lesions involving skin and other organs (Fig. 38.2B).
  - It is associated with HIV and other severely immunocompromised conditions.
  - It is caused by both *B. henselae* and *B. quintana*.
    - Skin lesions are caused by both species
    - Hepatosplenic lesions are caused by *B. henselae*; whereas subcutaneous and lytic bone lesions are caused by *B. quintana*.



Figs 38.2A to C: **A.** Enlarged lymph node of cat-scratch disease; **B.** Bacillary angiomatosis; **C.** Verruga peruana

Source: Centers for Disease Control and Prevention/NEJM *(with permission)*

TABLE 38.3: Features of *Bartonella* species

Bartonella	Diseases	Reservoir	Transmission
B. henselae	▪ Cat-scratch disease ▪ Bacillary angiomatosis ▪ Bacillary peliosis ▪ Bacteremia, endocarditis	Cats, Other felines	▪ Exposure to cat: by scratch or bite ▪ Cat fleas associated with cat-to-cat transmission, but not cat-to-human transmission
B. quintana	▪ Trench fever ▪ Chronic bacteremia, endocarditis ▪ Bacillary angiomatosis	Humans	Louse (*Pediculus humanus corporis*)
B. bacilliformis	▪ Bartonellosis (Carrion's disease) ▪ Oroya fever ▪ Verruga peruana (Fig. 38.2C)	Humans	Sandfly (*Lutzomyia verrucarum*)

- **Bacillary peliosis:** It is another angioproliferative disorder caused by *B. henselae*, involving liver (peliosis hepatitis), spleen and lymph nodes.
- **Bacteremia and endocarditis** may occur rarely.

Bartonella quintana

Bartonella quintana is transmitted to humans by body louse feces (auto inoculated into skin due to scratching). It causes trench fever, chronic bacteremia, endocarditis and bacillary angiomatosis.

Trench Fever (Quintan Fever)

- **Classical trench fever:** It was first seen causing epidemics in the trenches of World War I (1919) where it presented as periodic mild febrile illness lasting 4–5 days with 5-day intervals between the episodes (hence also called **5 days fever**). Thereafter, it was silent for decades.
- **Re-emerged trench fever**: The disease has re-emerged in USA recently. It presents with chronic bacteremia and endocarditis, seen most often in homeless people.

Bartonella bacilliformis

Bartonella bacilliformis is transmitted by vector sandfly (*Lutzomyia*). Humans are the only known reservoir. It produces a biphasic disease:

- **Oroya fever or Carrion's disease:** It is the initial, bacteremic, systemic illness presenting with or without anemia.
- **Verruga peruana:** It is a late-onset manifestation, characterized by cutaneous vascular lesions (Fig. 38.2C).

Laboratory Diagnosis of *Bartonella* Infections

- **Specimens** collected are blood, lymph node or skin biopsies.
- **Microscopy:** Warthin-Starry silver nitrate staining and immunofluorescence staining can be used to detect *B. henselae* from lymph node smears.
- **Culture:** *Bartonella* can be grown on blood agar at 37°C (except for *B. bacilliformis* at 30°C) in presence of 5% CO_2 and incubated for 12–15 days (maximum up to 45 days). Sensitivity can be increased after cell lysis or freezing the sample.
- **Antibody detection:** Both indirect immunofluorescence assay (IFA) and enzyme immunoassay (EIA) based methods are available to detect antibodies against *B. henselae* and *B. quintana* separately.
- **PCR:** It can be done to amplify the genes such as citrate synthase gene, 16S rRNA gene or heat-shock protein gene.

EXPECTED QUESTIONS

I. Essay:

1. Mr Sarvanan, a 29-year-old military Jawan was brought to the hospital in a state of altered sensorium, which he had developed a few hours ago. There was history of high grade fever and headache associated with vomiting for the past 2 days. On examination he was febrile (1020F), his blood pressure was 90/60 mm Hg. There were petechial rashes noted throughout his body except palm and sole. On enquiry, he was found to have exposed to body lice. Similar symptoms were also reported from a few members of his battalion.
   a. What is the most probable diagnosis?
   b. List the other agents of the family to which the causative agent belongs to with their modes of transmission and the diseases they cause?
   c. How this disease is diagnosed in the laboratory?

II. Write short notes on:

1. Scrub typhus
2. Cat-scratch disease
3. Bacillary angiomatosis
4. Ehrlichiosis
5. Q fever

III. Multiple Choice Questions (MCQs):

1. **Positive tunica reaction is produced by all except:**
   a. *R. prowazekii*
   b. *R. typhi*
   c. *R. conorii*
   d. *R. akari*
2. **All of the following rickettsiae belong to spotted fever group except:**
   a. *R. rickettsii*
   b. *R. conorii*
   c. *R. typhi*
   d. *R. akari*
3. **Tick is the vector for following rickettsial infections except:**
   a. *R. rickettsii*
   b. *R. akari*
   c. *R. africae*
   d. *R. conorii*
4. **All are true about *Coxiella burnetii* except:**
   a. It is obligate intracellular
   b. It causes 'Q fever'
   c. It is extremely fastidious
   d. It is killed by pasteurization

Answers

1. a **2.** c **3.** b **4.** d

CHAPTER 39

Chlamydiae

Chapter Preview

- General description
- Classification
- Chlamydia trachomatis
- Chlamydophila psittaci
- Chlamydophila pneumoniae
- Laboratory diagnosis of chlamydial infections
- Treatment and prevention

GENERAL DESCRIPTION

Chlamydiae are obligate intracellular bacteria that cause a spectrum of diseases in man such as trachoma, lymphogranuloma venereum (LGV), conjunctivitis, pneumonia and psittacosis and can also cause widespread diseases in birds and mammals.

Classification

Based on genetic characteristics, family Chlamydiaceae has undergone recent taxonomic changes. Previously, *Chlamydia* was the only genus under the family. But now, it comprises of two genera:

1. *Chlamydia*: It has one pathogenic species, *C.trachomatis.*
2. *Chlamydophila*: It consists of:
   - Two pathogenic species—*C. psittaci* and *C. pneumoniae.*
   - Several non-pathogenic animal species such as *C. pecorum, C. abortus, C. caviae* and *C. felis.*

Previous names: Based on the disease produced, chlamydiae were called previously as PLT agent (psittacosis-lymphogranuloma-trachoma) or TRIC organisms (trachoma-inclusion conjunctivitis).

Chlamydiae are Bacteria, Not Viruses

Chlamydiae were once thought to be viruses because of possessing a few viral properties, such as:

- They are obligately intracellular.
- They cannot be grown in artificial media (however they can grow in cell lines, embryonated egg or animals).
- Filterable—small enough to pass through bacterial filters
- Produce intracytoplasmic inclusions.

However, chlamydiae are now confirmed to be bacteria, because they have many other properties similar to that of bacteria, as follows:

- Possess both DNA and RNA.
- Their cell wall is similar to that of gram-negative bacteria (although they lack peptidoglycan layer).
- Multiply by binary fission.
- Contain prokaryotic 70S ribosomes.
- Capable of synthesizing their own nucleic acid, lipids and proteins.
- Susceptible to a wide range of antibacterial antibiotics.

Life Cycle

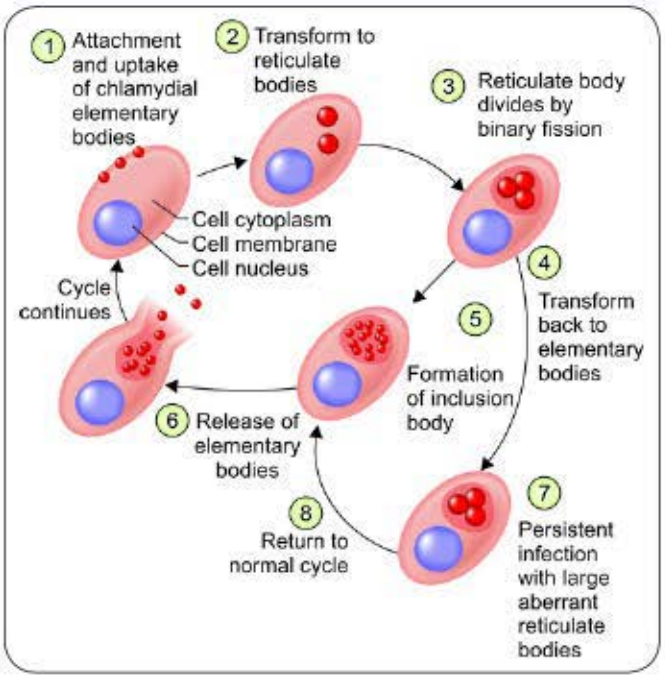
Chlamydiae exist in two distinct morphological forms—elementary body (EB) and reticulate body (RB) as shown in Table 39.1.

Chlamydiae have specific tropism for squamous epithelial cells and macrophages of the respiratory tract. The growth cycle is biphasic (i.e. alternates between EBs and RBs) and comprises of the following steps (Fig. 39.1).

- **Attachment:** Elementary bodies attach to the specific receptors on the surface of host cells following which they are endocytosed.

TABLE 39.1: Features of elementary and reticulate body

Elementary body	Reticulate body
Extracellular form	Intracellular form
Infectious form	Replicating form
Metabolically inactive	Metabolically active
Rigid cell wall	Fragile cell wall
Small size (0.20–0.30 µm)	Large size (1–1.5 µm)
Nucleoid is electron dense	Nucleoid is diffuse
DNA and RNA contents are same	RNA content is more than DNA



1 Attachment and uptake of chlamydial elementary bodies
2 Transform to reticulate bodies
3 Reticulate body divides by binary fission
Cell cytoplasm
Cell membrane
Cell nucleus
4 Transform back to elementary bodies
5 Formation of inclusion body
6 Release of elementary bodies
Cycle continues
7 Persistent infection with large aberrant reticulate bodies
8 Return to normal cycle

Fig. 39.1: Life cycle of *Chlamydia*

Abbreviations: EB, elementary body; RB, reticulate body; IFN, interferons

- **Intracellular survival:** Elementary body resides inside the vacuole (phagosome), where the entire growth cycle is completed. They prevent phagosome-lysosome fusion by inserting chlamydial antigens on to the phagosomal membrane.
- **Transform to reticulate bodies:** By 12 hours of infection the elementary bodies enlarge containing diffuse nucleoid.
- **Replication:** Reticulate bodies start to divide by binary fission within 18 hours. They are the metabolically active form, capable of synthesizing their own nucleic acid, lipids and proteins except ATP (lack enzymes of electron transport chain). Hence, chlamydiae are also called as **energy parasites** as they depend on host ATP for survival.
- **Transform back to elementary bodies:** By 18–24 hours of infection, the reticulate bodies gradually reorganize to form elementary bodies.
- **Inclusion body:** The vacuoles gradually increase in size to form inclusion body which can be readily detected by histologic stains.
- **Release:** Mature inclusion body contains 100-500 elementary bodies which are ultimately released from the host cell by 48 hours.
- **Persistent infection:** Sometimes, the development is arrested at the reticulate body stage, leading to persistent (or latent) infection.
  - This plays an important role in ocular, chronic genital infections and possible role of *C. pneumoniae* in coronary atherosclerosis.
  - Many factors, such as the interferon-γ or antibiotics (penicillin) or deprivation of tryptophan and cysteine may facilitate the arrest of life cycle.

Antigenic Structure

Chlamydiae possess the following antigens:

- **Genus/group specific antigen:** Chlamydial lipopolysaccharide (LPS) is genus specific; it is similar to the LPS present in the other gram-negative bacteria.
  - In addition, family Chlamydiaceae carries a specific antigen—3-deoxy-manno-octulosonic acid.
  - LPS is used in complement fixation test to detect genus specific antibodies.
  - LPS is also important in the pathogenesis, by induction of TNF-α and other proinflammatory cytokines, leading to scarring and fibrosis.
- **Species specific protein antigens:** They are present at the envelope surface. They help in classifying chlamydiae into different species.
- **Serovar-specific antigens:** They are the major outer membrane proteins (MOMP). They are used in micro-immunofluorescence test to detect serovar-specific antibodies.
- **Other antigens:** Such as outer membrane complex proteins, type III secretory system and heat shock proteins play important role in pathogenesis.

CHLAMYDIA TRACHOMATIS

Chlamydia trachomatis is primarily a human pathogen, causing ocular, urogenital and neonatal infections.

Typing of Chlamydia

Biovars

Historically, based on disease the produced, *C. trachomatis* was subdivided into two strains or biovars (Table 39.2).

1. TRIC (Trachoma-inclusion conjunctivitis)
2. Lymphogranuloma venereum (LGV) biovar

Serotyping

Based on antigenic structure of major outer membrane protein (MOMP) of *C. trachomatis*, 18 serovars have been identified affecting humans.

- Serovars A, B, Ba and C are associated primarily with ocular disease called trachoma.
- Serovars D–K are associated with oculogenital disease, which may be transmitted to neonates.
- Serovars L1–L3 causes a sexually transmitted disease, lymphogranuloma venereum (LGV).

TABLE 39.2: Features of *Chlamydia* infections

Species	Character	Biovar	Serotype	Disease
C. trachomatis	▪ Forms compact inclusions mixed with glycogen matrix ▪ Sensitive to sulfonamide ▪ Natural human pathogen ▪ Leaves the host cell with a scar	TRIC	A, B, Ba, C	Trachoma
			D-K	▪ Genital chlamydiasis ▪ Inclusion conjunctivitis ▪ Infant pneumonia
		LGV	L1, L2, L3	Lymphogranuloma venereum
C. psittaci	▪ Forms diffuse vacuolated inclusions without glycogen matrix ▪ Resistant to sulfonamide ▪ Natural pathogen of birds ▪ Leaves the host cell by lysis	Nil	Many serotypes	▪ Psittacosis (Atypical pneumonia) ▪ Transmission-Inhalational route - pet birds (parrots) and poultry (turkeys and ducks) ▪ No man-to-man transmission
C. pneumoniae TWAR agent	▪ Exclusive human pathogen ▪ Forms inclusions without glycogen matrix ▪ Resistant to sulfonamide	Nil	Only 1 serotype	▪ Community-acquired atypical pneumonia ▪ Associated with– • Atherosclerosis • Asthma

Abbreviations: Biovar TRIC, trachoma Inclusion conjunctivitis; Biovar LGV, lymphogranuloma venereum; TWAR agent, Taiwan acute respiratory agent

C. trachomatis Serovars A, B, Ba and C (Trachoma)

Trachoma is a chronic keratoconjunctivitis, caused by *C. trachomatis* serovars A, B, Ba and C.

- **Mode of transmission:** Trachoma is transmitted through direct contact (fingers and fomites) with discharges from the eyes of the infected patients or indirect contact through contaminated clothes or flies.
- **Age:** Infection is acquired by 2–3 years of age and active disease is most common among young children.
- **Acute infection** presents as:
  - Follicular conjunctivitis (inflammation of conjunctival lymphoid follicles) and papillary hyperplasia.
  - Follicles rupture to leave shallow pits termed Herbert's pits.
  - Cornea gets infected (keratitis).
- **Late stage (cicatrization):**
  - Recurrent infection leads to conjunctival scarring or cicatrization which may occur at sclera-conjunctiva junction (limbal scarring) or on palpebral conjunctiva.
  - New vessel formation takes place (pannus).
  - Eyelashes become wet and turn inward (entropion), which may rub on the corneal surface (trichiasis).
  - Repeated rubbing of cornea may lead to opacity, which results in impaired vision or blindness.
- **WHO classification:** World Health Organization recommends a simplified grading system for trachoma, which is used clinically.
- **Epidemiology:** Trachoma is a disease of developing nations.
  - Worldwide, the hyperendemic areas of trachoma include sub-Saharan Africa, Middle East, and Southeast Asia including India.
  - Trachoma still continues to be a leading cause of preventable infectious blindness worldwide.

C. trachomatis Serovars D–K

The infections produced by *C. trachomatis* serovars D–K are as follows.

Genital Infections

- **Nongonococcal urethritis (NGU):** *Chlamydia trachomatis* is the most common cause of nongonococcal urethritis (NGU), responsible for 30–50% of cases of NGU. It differs from gonococcal urethritis (GU) by—
  - Onset of symptoms (incubation period—7–10 days, compared with 2–5 days for GU).
  - Symptoms: Mucopurulent discharge is followed by dysuria and urethral irritation (GU has purulent discharge).
- **Postgonococcal urethritis (PGU)**
  - *C. trachomatis* is the most common cause of PGU.
  - Urethritis develops in men 2–3 weeks after recovery from GU.
  - This occurs when patients with GU are treated with penicillin or cephalosporin alone without adding any antichlamydial drugs.
- **Epididymitis and proctitis:** *C. trachomatis* is the most common cause of epididymitis in males.
- **Reactive arthritis (Reiter's syndrome):** It consists of conjunctivitis, urethritis (or, in females-cervicitis), arthritis, and characteristic mucocutaneous lesions.
  - It occurs in 1–2% of cases of NGU, develops after 1–4 weeks after genital infection.
  - Men are more frequently affected than women (10:1).
  - It is the most common cause of peripheral inflammatory arthritis in young men.

- Large joints, particularly of the legs, or the sacroiliac joints are commonly affected.
- Most of the patients possess HLA-B27 haplotype.
- **Mechanism:** It is an immune-mediated inflammatory response to an infection at a distant site. *C. trachomatis* may act as a trigger organism that enhances immune response in susceptible individuals but is not responsible for all the cases.
- Resolution usually occurs without specific treatment, but relapse is common.

- **In females:**
  - Mucopurulent cervicitis is the most common manifestation.
  - It may progress to endometritis, salpingitis (fallopian tube), PID (pelvic inflammatory disease) and finally pelvic peritonitis.
  - Perihepatitis (Fitz–Hugh–Curtis syndrome).

Inclusion Conjunctivitis

C. trachomatis serovars D–K cause the following ocular infections:

- **Ophthalmia neonatorum** (or inclusion blennorrhea) occurs in the new borne.
  - *C. trachomatis* is more common cause of ophthalmia neonatorum than gonococcus.
  - Incubation period is longer for chlamydial infection (6–21 days) and discharge is mucopurulent compared to gonococcus (48 hours incubation period, purulent and crusted discharge).
- **Adult inclusion conjunctivitis:** It is an acute follicular conjunctivitis, that may occur in adults following swimming (swimming pool conjunctivitis).

Infant Pneumonia

- It is an interstitial pneumonia that develops within 3 weeks to 3 months of birth.
- Infection spreads from conjunctiva to pharynx via the nasolacrimal duct.
- Infection via the eustachian tube may cause otitis media.

C. trachomatis Serovar L1, L2, and L3

C. trachomatis serovar L1, L2, and L3 are the agents of lymphogranuloma venereum (LGV).

Lymphogranuloma Venereum

Lymphogranuloma venereum (LGV) is an invasive systemic sexually transmitted disease, characterized by—

- **First stage:** Painless papule, ulcer or vesicle develops on the penis or vulva after an incubation period of 3 days to 6 weeks.
- **Second stage:**
  - Inguinal lymph nodes in the groin become enlarged, tender and soft (called **bubo**).
  - Fistulae-buboes may breakdown and discharge may spread externally as chronic fistulae.
  - Systemic symptoms may develop such as fever, headache and myalgia.
- **Third stage:** Occurs in untreated cases, especially in women and homosexual men.
  - Rectal stricture or rectovaginal and rectal fistulae may occur.
  - Esthiomene-the vulva, scrotum or penis may undergo edematous granulomatous hypertrophy ('esthiomene' in Greek meaning 'eating away').
  - Elephantiasis of the vulva or scrotum may occur due to impaired lymphatic drainage that is endemic in tropics, notably Africa and India.
- **Epidemiology:** Though the incidence of LGV is decreasing; it is still endemic in Southeast Asia (including India), South America and Caribbean.

CHLAMYDOPHILA PSITTACI

C. psittaci is a pathogen of parrots and other psittacine birds causing psittacosis. A similar disease of non-psittacine birds was previously called ornithosis, but now it is merged with psittacosis.

- **Reservoirs:** Pet birds (parrots, parakeets, macaws, and cockatiels) and poultry (turkeys and ducks) act as natural reservoir of infection and are involved in transmission of infection to humans (Table 39.2).
- **Mode of transmission:** *C. psittaci* can be transmitted to humans by—
  - Inhalation of aerosols from avian nasal discharges and from infectious avian fecal or feather dust.
  - Direct contact with infected birds.
  - There is no person to person transmission.
- **Clinical manifestations:** Incubation period is usually 5–19 days. It can present as:
  - Respiratory manifestation is the most common form, varies from a mild influenza-like syndrome to a fatal pneumonia.
  - Septicemia occurs which may lead to meningoencephalitis, endocarditis, pericarditis, arthritis and gastrointestinal symptoms.
  - Typhoid-like syndrome characterized by fever, hepatosplenomegaly and Horder's spots (rashes resembling the rose spots of typhoid fever).
- **Epidemiology:** Due to control of birds and improved veterinary-hygienic measures, cases of psittacosis are now rare.

CHLAMYDOPHILA PNEUMONIAE

C. pneumoniae is an exclusively human pathogen. It is transmitted from person to person by inhalational route. It causes various manifestations (Table 39. 2).

- **Atypical pneumonia:** *C. pneumoniae* is a common cause of atypical (interstitial) pneumonia accounting for 10% of cases of community-acquired pneumonia.
  - Symptoms are similar to that caused by *Mycoplasma pneumoniae* such as fever, non-productive cough and absence of leukocytosis.
  - Upper respiratory tract involvement is frequent such as pharyngitis and sinusitis.
- **Atherosclerosis:** There is strong evidence of association between *C. pneumoniae* and atherosclerosis of coronary and other arteries.
  - Antibodies are often elevated and *C. pneumoniae* has been recovered from atheromatous plaques.
  - One hypothesis says that antibodies to outer membrane protein of *C. pneumoniae* may cross-react with human proteins resulting in an autoimmune reaction.
- **Asthma and COPD:** *C. pneumoniae* may cause exacerbations of bronchial asthma and COPD (chronic obstructive pulmonary disease).

LABORATORY DIAGNOSIS — Chlamydial infections

- **Specimen:** Depends on the type of lesions.
- **Microscopy:** Detects chlamydial inclusion bodies.
  - Gram staining, Lugol's iodine and other stains such as Castaneda, Machiavello or Gimenez stains.
  - Direct IF: Used for direct detection of inclusion bodies.
- **Antigen detection (LPS antigens):** By enzyme immunoassays.
- **Culture:** The gold standard method in the past.
  - Egg (yolk sac), mice inoculation and cell line culture.
  - Cell lines of choice-
    - McCoy, HeLa (for *C.trachomatis*)
    - HEp2 (for *C.pneumoniae*)
- **Nucleic acid amplification tests (NAAT),** e.g. PCR
  - The most sensitive and specific method.
  - Currently the diagnostic assays of choice.
- **Serology (antibody detection):**
  - CFT using group specific LPS antigen.
  - Micro-IF test detects antibody against species and serovar specific MOMP antigen.

LABORATORY DIAGNOSIS OF CHLAMYDIAL INFECTIONS (TABLE 39.3)

Specimen Collection

- Scrapings or swabs from infected sites: As chlamydiae are intracellular, so the sample must contain cells.

TABLE 39.3: Laboratory diagnosis of chlamydial infections

Clinical presentation	Specimen	Recommended laboratory test
Genital infections		
Urethritis (NGU) and cervicitis (*C. trachomatis* D–K)	Urethral swab or endocervical swab	NAAT, direct detection (EIA and DIF)
	First-catch urine in the morning	NAAT, direct detection (EIA and DIF)
Pelvic inflammatory disease/ Fitz–Hugh–Curtis syndrome (*C. trachomatis* D–K)	Endocervical swab, fallopian/ peritoneal swab	NAAT, antigen detection (EIA and DIF), culture
Lymphogranuloma venereum (*C. trachomatis* L1–L3)	Serum	Antibody detection (ELISA, MIF, CFT)
	Scrapping from ulcer base	Direct detection (EIA and DIF), culture
	Lymph node aspirate	Culture
Ocular infections		
Trachoma (*C. trachomatis* A–C)	Conjunctival swab (upper)	NAAT, direct detection (EIA and DIF), culture
Ophthalmia neonatorum (*C. trachomatis* D–K)	Conjunctival swab (lower)	
Pulmonary infections		
Infant pneumonia (*C. trachomatis* D–K)	Serum	IgM antibody detection (EIA, MIF)
	Nasopharyngeal aspirate	NAAT, direct detection (EIA and DIF), culture
Psittacosis (*C. psittaci*)	Serum	Antibody detection (MIF, CFT)
Community-acquired pneumonia (*C. pneumoniae*)	Serum	Antibody detection (MIF)
	Respiratory secretions	Direct detection (EIA and DIF)

Abbreviations: CFT, complement fixation test; DIF, direct immunofluorescence test; EIA, enzyme immunoassay; MIF, microimmunofluorescence; NAAT, nucleic acid amplification tests.

Hence, firm scraping or swabbing of the site is required. Recommended specimens are:
- Urethral swab for NGU
- Endocervical swab for cervicitis
- Conjunctival swabs for ocular infections-upper conjunctiva for trachoma and lower conjunctiva for ophthalmia neonatorum.

- First catch urine samples in the morning contain greatest amount of urethral secretions, hence it is the preferred specimen for urethritis or cervicitis.
- Nasopharyngeal aspirate and respiratory secretions for pneumonia.
- Bubo aspirate for LGV.

Microscopy

- **Gram staining:** Though, chlamydiae are gram-negative they are poorly stained.
- **Presumptive diagnosis:** Routine Gram-staining often reveals sterile pyuria (i.e. elevated neutrophils without any organisms, including gonococci). In such a case any other diagnostic test should be performed for confirmation. Presumptive diagnosis is usually made based on neutrophil count—
  - NGU, post gonococcal urethritis, epididymitis, reactive arthritis more than 4 neutrophils per oil immersion field (OIF).
  - Cervicitis more than 20 neutrophils per OIF.
  - Proctitis more than 1 neutrophils per OIF.
- **Other stains:** Such as Castaneda, Machiavello or Gimenez stains are better methods to detect chlamydiae from samples. The inclusion bodies can be detected in cytoplasm (Fig. 39.2).
- **Lugol's iodine:** The inclusion bodies of *C.trachomatis* can be stained with Lugol's iodine because of the presence of glycogen matrix. Whereas the inclusion bodies of *C. psittaci* are diffuse vacuolated, without glycogen matrix, hence does not take up the iodine stain.
- **Inclusion bodies:** They are given various names such as:
  - Halberstaedter–Prowazek (H–P) body in trachoma.
  - Miyagawa corpuscle in LGV.
  - LCL body (Levinthal-Cole-Lillie) body in psittacosis.

Direct Immunofluorescence Test (DIF)

DIF is used as for direct detection of inclusion bodies in clinical material, particularly from the genital tract and eye or can also be used for culture confirmation.
- Swabs are rolled on to a teflon-coated slide, and then fixed in methanol. Fluorescent tagged monoclonal antibodies directed against group-specific LPS antigen or species-specific MOPP antigens are added.
- Though, DIF is sensitive, but the specificity is low because of the non-specific fluorescence.

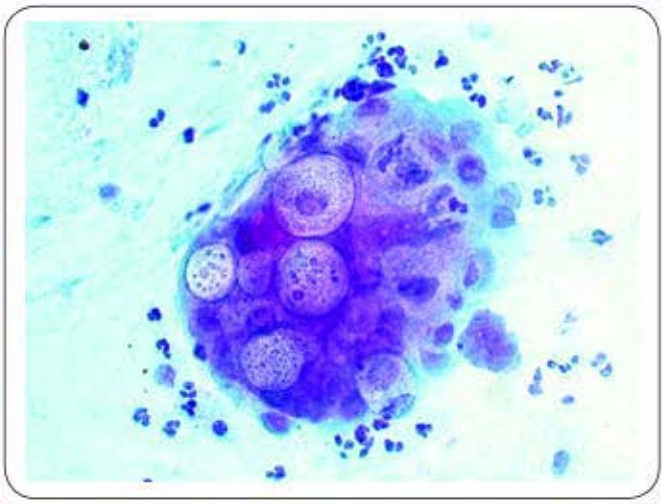


Fig. 39.2: *Chlamydia* elementary bodies (coarse granules within vacuoles)

Source: PathologyOutlines.com (*with permission*)

Enzyme Immunoassays (Antigen Detection)

EIA detects chlamydial group specific antigens (LPS) from the samples by using specific monoclonal antibodies.
- It is sensitive (60–80%), rapid, easy to perform.
- However, the specificity is low and has to be confirmed by NAAT or DIF.

Culture

Chlamydiae cannot be cultivated in artificial media. They can grow only in embryonated egg (yolk sac), animal (mice) and cell line.
- Both egg and mice inoculation methods are no longer in use.
- Mice inoculation was used in the past for isolation of *C. psittaci* and LGV serovars of *C. trachomatis*. Others are not infective to mice.
- **Cell line culture** is the traditional method of diagnosis in the past, was considered as the gold standard method.
  - Though highly specific, it is less sensitive (90% compared with NAATs), time consuming, technically demanding and labor intensive.
  - **Choice of the cell line** depends on the species—
    - *C. trachomatis* recommended cell lines are McCoy, HeLa 229, buffalo, green monkey and baby hamster kidney (BHK-21) cell lines.
    - *C. pneumoniae* can be isolated from HEp2 or human fibroblast cell line.
    - *C. psittaci* although grow well in cell culture, isolation should not be attempted in the routine laboratory because of the risk of laboratory infection.

- **Procedure:**
  - Cell lines should be in their stationary phase of growth before inoculation of specimens. This may be achieved by treatment with γ-radiation or idoxyuridine or cycloheximide.
  - **Promote contact:** Pre-treatment of cell lines with diethylaminoethanol (DEAE) dextran or centrifugation after inoculation of specimen should be done to promote contact between chlamydiae and the cells, thus increasing the chance of isolation.
  - **Incubation:** Cultures are incubated in 10% CO_2 for 48–72 hours (shorter for *C. trachomatis* and longer for others).
  - **Detection:** Cell lines are then stained to demonstrate the presence of inclusions as described under microscopy (Fig. 39.3).

Nucleic Acid Amplification Tests (NAAT)

NAAT have revolutionized the diagnosis of chlamydial infections.

- **Advantages:** NAAT is highly sensitive and specific, takes less time, and detects even few copies of DNA from the sample. It can also differentiate the species and serovars.
- NAATs are currently the diagnostic assays of choice for chlamydial infection as recommended by the CDC, replacing the so called gold standard culture methods.
- Various methods available are:
  - Polymerase chain reaction (PCR)
  - Ligase chain reaction (LCR)
  - Transcription-mediated amplification (TMA)
  - Strand displacement assay (SDA).

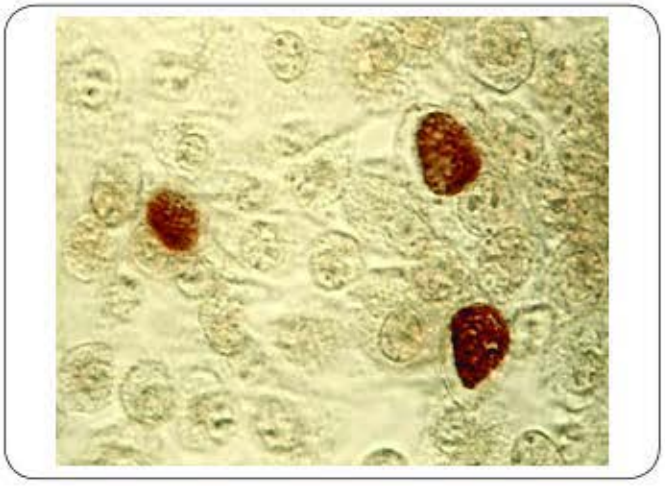

Fig. 39.3: *Chlamydia trachomatis* inclusion bodies (brown) in a McCoy cell culture

Source: Public Health Image Library/ ID#: 3802, Dr E Arum; Dr N Jacobs, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Serology (Antibody Detection)

Serological tests are useful for LGV, infant pneumonia and psittacosis (systemic infections).

- **CFT** (complement fixation test) using LPS antigen was used in the past; which is group specific and cannot distinguish between species. Titer of ≥1:64 is considered significant.
- **ELISA** based formats are also available using recombinant LPS antigen.
- **Microimmunofluorescence (MIF)** test uses the species and serovar specific MOMP (major outer membrane protein) antigen.
  - Serovar and species-specific antigens are spotted onto slides and incubated with serial dilutions of patient's serum. After incubation and washing, antigen antibody complex is detected by fluorescein tagged antihuman globulin.
  - MIF is the best antibody detection test available at present. It can detect IgM and IgG separately.
  - Still MIF is not widely used, because the procedure is highly technically demanding and labor intensive.
  - Single high titer of ≥1:512 is diagnostic, however fourfold rise of titer at 2–3 weeks interval is more significant.

TREATMENT — Chlamydia infections

Chlamydia Trachomatis

- **For uncomplicated genital infection or trachoma or adult conjunctivitis:**
  - Azithromycin is the drug of choice given as single dose of 1 gram tablet.
  - Alternatively doxycycline, tetracycline, erythromycin or ofloxacin can be given for at least a duration of 7 days.
  - Both the sex partners should be treated.
  - Ceftriaxone should be added to the regimen as co-infection with gonococcus may be present in most of the cases.
- **For complicated genital infection:** Doxycycline (100 mg twice daily), or erythromycin (500 mg four times daily) are the drugs of choice, given for:
  - 2 weeks for PID, epididymitis
  - 3 weeks for LGV
- **For neonatal infections (ophthalmia neonatorum and infant pneumonia):**
  - Erythromycin is given orally at a dosage of 50 mg/kg per day in four divided doses, for 2 weeks.
  - Topical ointments (erythromycin) can be used in addition to oral therapy for eye infections but relapse is common if used alone.

Chlamydophila Psittaci

Tetracycline is the drug of choice, given 250 mg four times a day for at least 3 weeks to avoid relapse. Erythromycin (500 mg four times a day by orally) is given as alternate.

Chlamydophila Pneumoniae

Tetracycline or erythromycin (500 mg four times a day) is recommended for 14 days.

Prevention

Control measures for prevention of genital infections include:

- Periodic screening of high risk groups, such as young women having multiple sex partners.
- Treatment of both the sex partners.
- Use of barrier methods of contraception such as condoms.

EXPECTED QUESTIONS

I. Essay:

1. A 27-year-woman had developed mucopurulent discharge, followed by development of dysuria and urethral irritation. She had a history of multiple sexual partners. Microscopy of the urethral swab revealed sterile pyuria and presence of compact inclusion bodies which are later stained by Lugol's iodine.
   a. What is the most probable etiological diagnosis?
   b. What are the other manifestations produced by the causative agent?
   c. How is this infection diagnosed in the laboratory?

II. Write short notes on:

1. Psittacosis
2. Lymphogranuloma venereum
3. Nongonococcal urethritis
4. Reiter's syndrome

III. Multiple Choice Questions (MCQs):

1. Lugol's iodine is used to stain the inclusion body of:
   a. *Chlamydia trachomatis*
   b. *Chlamydophila psittaci*
   c. *Chlamydophila pneumoniae*
   d. All of the above

2. All of the following are true except:
   a. Elementary body is metablically active
   b. Reticulate body is the replicating form
   c. Reticulate body is intracellular form
   d. Elementary body is infectious form

3. The most commonly used method for isolation of *Chlamydia*:
   a. Culture on artificial media
   b. Culture on Vero cell line
   c. Inoculation into guinea pig
   d. Culture on McCoy cell line

4. The most sensitive and specific test for *Chlamydia* diagnosis:
   a. Direct immunofluorescence test (DIF)
   b. Culture on McCoy cell line
   c. Nucleic acid amplification tests (NAAT)
   d. Micro-immunofluorescence (MIF) test

CHAPTER 40

Mycoplasma and Ureaplasma

Chapter Preview

- Introduction and Classification
- Mycoplasma pneumoniae
- Urogenital mycoplasmas

INTRODUCTION

Mycoplasmas are the smallest microbes capable of free-living in the environment and self-replicating on artificial culture media. They have the following characteristics as mentioned below:

- They resemble to viruses in certain properties such as:
  - Size: They are very small, 150–350 nm in size
  - They are filterable by bacterial filters
- They differ from viruses as:
  - They are **free living** in the environment
  - They can grow on artificial cell-free culture media.
- They **lack a rigid cell wall**, which is replaced by a triple-layered cell membrane containing sterol.
- They are completely resistant to antibiotics acting on cell wall such as β-lactams.
- **Pleomorphic**: They are highly pleomorphic, exist in coccoid, bacillary or filamentous or even in helical forms (*Spiroplasmas*).
- They are poorly gram-negative, better stained by Giemsa stain.
- They reproduce by binary fission and budding
- They are non-sporing and non-flagellated, usually non-motile. However, **gliding motility** is described in some species which is due to their specialized tip structures.
- **Contaminants of cell cultures:** Mycoplasmas are common contaminants of continuous cell cultures, thus interferes with the growth of viruses in cell cultures.

Mycoplasmas and L-form

- L-forms (after Lister Institute, London) as described by Kleineberger (1935) are cell wall deficient forms. They lose their cell wall either spontaneously or on exposure to cell wall acting antibiotics (like β-lactams), and usually revert back once the antibiotic exposure is withdrawn.
- Mycoplasmas lack cell wall permanently and differ from L-forms in many ways (Table 40.1). It has been suggested that mycoplasmas may represent stable L-forms of bacteria but genetic, antigenic and biochemical properties do not support this hypothesis.

History

Pleuropneumonia-like organisms (PPLO): Nocard and Roux (1898) were the first to isolate mycoplasma as a filterable and highly pleomorphic microorganism from bovine pleuropneumonia.

- Later on, it was termed as *Mycoplasma* (derived from *Myco* meaning fungus-like, forming branching filaments; *plasma*, denoting their plasticity of shape).
- **Eaton's agent:** It refers to the most pathogenic species i.e. *Mycoplasma pneumoniae;* which was first isolated by Monroe Eaton (1944).

Classification

Mycoplasmas belong to class Mollicutes (mollis—soft; cutis—skin, in Latin), order Mycoplasmatales, which in turn comprises of the five families. The term mycoplasmas and class Mollicutes, are often used interchangeably.

TABLE 40.1: Comparison of *Mycoplasma* and L-forms

Mycoplasma	L-forms
Stable, cell wall is absent permanently	**Two types:** **Unstable L- forms:** They usually revert back to normal state once the antibiotic exposure is withdrawn **Stable L-forms:** They are permanently cell wall deficient but resemble parent bacteria both biochemically and antigenically
Absence of precursors of peptidoglycan	Though cell wall deficient, remnants of cell wall components can be demonstrated
Cell membrane contains sterols	Sterols absent
Filterable like viruses	Not filterable
Mycoplasma can cause disease in cell wall deficient form	L-forms do not cause disease but they play an important role in persistence of infection during antibiotic therapy

- Members of most of the families infect plants, insects and animals, except family Mycoplasmataceae which is of human importance.
- Family Mycoplasmataceae comprises of two genera—*Mycoplasma* and *Ureaplasma;* both infect humans and animals.
- Out of 16 species of *Mycoplasma* and *Ureaplasma* infecting humans, five are established pathogens, rest are normal flora of oral and urogenital tract. The human pathogenic species are:
  - *Mycoplasma pneumoniae* causing pneumonia
  - Others cause genital tract infections, such as:
    - *Mycoplasma hominis*
    - *Mycoplasma genitalium*
    - *Ureaplasma urealyticum*
    - *Ureaplasma parvum*

MYCOPLASMA PNEUMONIAE

M. pneumoniae is the causative agent of primary atypical pneumonia.

Antigens

Mycoplasma possesses several cell membrane antigens which probably play an essential role in the host response to infection.

- **Glycolipid antigen**: It is nonspecific, found in diverse tissues, forms the basis of detection of heterophile antibodies (cold agglutination test).
- **Membrane bound proteins** (e.g. cytadhesin P1 protein): They help in attachment to host cell surface.

Pathogenesis

Pathogenesis of *M. pneumoniae* involves the following events:

- **Adhesion**: Attachment to respiratory mucosa is the most important step in pathogenesis,which is mediated by membrane bound adhesion proteins that are clustered to form complex terminal organelle at the tip of the organism.
- **Induces injury to host respiratory tissue:** This is mediated by producing:
  - Hydrogen peroxide
  - **Cytotoxin**: It is a recently identified toxin, has ADP ribosylating and vacuolating properties similar to pertussis toxin.
  - **Lipoproteins:** They are present in the cell membrane and appear to induce inflammation.

Host Immunity

Host immunity plays a crucial role in controlling *Mycoplasma* infection.

- **Cellular immunity:** This has an immuno-pathogenic role, exacerbating pneumonia caused by *Mycoplasma*.
- **Humoral immunity**: It does not protect from early disease; however, it provides protection against disseminated *Mycoplasma* infections such as arthritis, meningitis, and osteomyelitis.

Epidemiology

Mycoplasma pneumoniae infection occurs worldwide.

- **Transmission**: *M. pneumoniae* is transmitted by respiratory droplets expectorated during coughing.
- **Facilitating factors**: The transmission is favored by close contacts as in families, military bases, boarding schools, and summer camps.
- Infections tend to be endemic, with periodic epidemics every 4–7 years.
- Incubation period is about 2–4 weeks.

Clinical Manifestations

M. pneumoniae produces various infections; which are as follows:

Upper Respiratory Tract Infections (URTI)

URTI manifests as pharyngitis, tracheobronchitis or rarely otitis media. It is acute in onset and is 20 times more common than pneumonia.

Pneumonia

M. pneumoniae causes "**atypical**" community acquired interstitial pneumonia similar to pneumonia caused by other agents, such as *Chlamydophila pneumoniae, Legionella pneumophila* and viral pneumonia.

- This is also referred to as Eaton agent pneumonia, **primary atypical pneumonia** and walking pneumonia.
- Pneumonia develops in 3–13% of infected individuals; its onset is usually gradual.
- It is characterized by wheeze or rales, dry cough and peribronchial pneumonia with thickened bronchial markings and streaks of interstitial infiltration on chest X-ray.

Extrapulmonary Manifestations

They are rare, occur either as a result of active *Mycoplasma* infection (e.g. septic arthritis) or due to post infectious autoimmune phenomena (e.g. Guillain–Barré syndrome). Various manifestations include:

- **Neurologic:** Meningoencephalitis, encephalitis, Guillain–Barré syndrome and aseptic meningitis.
- **Dermatologic:** Skin rashes including erythema multiforme major (Stevens–Johnson syndrome).
- **Cardiac:** Myocarditis, pericarditis
- **Rheumatologic:** Reactive arthritis
- **Hematologic:** Anemia and hypercoagulopathy.

LABORATORY DIAGNOSIS *Mycoplasma pneumoniae*

- **Specimen:** Throat swabs and nasopharyngeal aspirates
- **Culture:**
  - Solid medium containing PPLO agar: Produces fried egg appearance colonies
  - Liquid medium containing PPLO broth: Produces turbidity and a color change.
- **Antigenic detection:** By Direct IF, antigen capture ELISA
- **Antibody detection in serum:**
  - Specific CFT, indirect-IF, LAT and ELISA using protein P1 antigens
  - Non-Specific: Cold agglutination test and *Streptococcus* MG test
- **Molecular methods:** Detects 16S rRNA and P1adhesin gene

Laboratory Diagnosis

Specimen Collection and Transport

Ideal specimens are throat swabs and nasopharyngeal aspirates, bronchial brushing, bronchoalveolar lavages and lung biopsies. Sputum is not very useful as it contains too many contaminants.

- Specimens must be placed immediately into the following transport media to avoid drying:
  - **Standard *Mycoplasma* fluid medium** containing fetal bovine serum, gelatine and penicillin.
  - **Viral transport medium,** added with ampicillin and cefotaxime.
- Transportation should be immediate. If delay is expected, then specimens should be stored at 4°C for 48 hours and beyond that at –70°C.

Culture

Primary isolation of *Mycoplasma* requires complex media, such as:

- **Standard solid medium:** Containing PPLO agar, horse serum and penicillin.
- **Standard liquid medium:** Containing PPLO broth, glucose and penicillin and phenol red (indicator).
- **Diphasic medium**: Contains both standard solid phase and liquid phase as described above.
- **SP-4 medium:** It is more complex and contains fetal bovine serum.
- **Hayflick modified medium:** Containing heart infusion broth.

Specimens are inoculated in culture media and incubated at 37°C for 5–7 days or sometimes even up to 1–3 weeks. Growth is detected as follows:

- **In liquid medium:** *M. pneumoniae* growth is detected by turbidity and a color change (red to yellow) of phenol red indicator due to fermentation of glucose. *Ureaplasma* and some other mycoplasmas do not ferment glucose and show only turbidity.

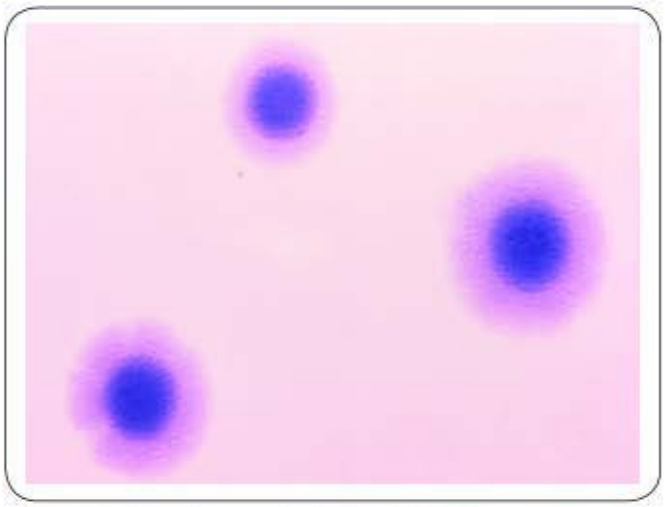

Fig. 40.1: *Mycoplasma* colonies (typical fried egg appearance)

Source: Public Health Image Library, ID# 11024/Dr. E. Arum; Dr.N. Jacobs/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **In solid medium:** The colonies appear as described below.
  - **Shape:** Colonies are embedded on agar surface and consist of a central opaque granular area of growth, surrounded by a flat, translucent peripheral growth-**described as fried egg appearance.** (Fig. 40.1).
  - **Size**: Colony size varies from 200–500 µm for mycoplasmas and 15–60 µm for ureaplasmas.
  - **Colonies can be examined by:**
    - Hand lens
    - Dienes' staining: Plate is flooded with alcoholic solution of methylene blue and azure, and examined under low power microscope. Mycoplasmas retain color for at least 2 days and appear intense royal blue, where as ureaplasmas appear reddish to greenish blue.

Identification

Colonies of *M. pneumoniae* may be further identified by:

- Most strains of *M. pneumoniae* produce hemolytic colonies.
- **Hemadsorption test:** *M. pneumoniae* agglutinates guinea pig red blood cells (RBCs) and the colonies on agar adsorb RBCs to their surface.
- **Tetrazolium reduction test**: *M. pneumoniae* colonies reduce the colorless tetrazolium compound to red colored formazan.
- **Growth inhibition test:** The growth of *M. pneumoniae* is inhibited by adding specific antisera.

Antigenic Detection

- Direct immunofluorescence test: Detects the *Mycoplasma* antigens directly in the clinical specimens.

- Capture ELISA assay is available using monoclonal antibodies against P1 adhesin antigen.

Antibody Detection in Serum

Specific Antibody Detection Tests

Antibodies specific to *M. pneumoniae* protein and glycolipid antigens can be detected after about 1 week of illness, and peak at 3–6 weeks and then decline gradually.

IgM antibodies are frequently elevated in children with acute infection where as in adults; on the contrary, IgA-antibody detection remains a method of choice for the diagnosis of acute infection.

Various specific antibody detection tests are as follows:

- **Complement fixation test (CFT):** It detects antibodies to glycolipid antigen. It was the reference test in the past; now not in use.
- **Alternative techniques** with greater sensitivity are:
  - Immunofluorescence assays
  - Latex agglutination assays
  - ELISA using protein P1 antigens

Nonspecific Antibody Detection Tests

Mycoplasma possesses certain heterophile antigens such as surface glycolipid haptens that cross react with 'I' antigens of the RBCs or carbohydrate antigens of group F *Streptococcus* cell wall. This property can be used to detect heterophile antibodies in patient's sera by using non-specific antigens.

- **Cold agglutination test:** It uses human O blood group RBC ('I' antigen) and test is carried out at 4°C.
- ***Streptococcus* MG tests:** It uses killed suspension of *Streptococcus* MG (group F *Streptococcus*).

However, these tests are less commonly used now days as they are neither specific nor sensitive (positive only in 30–50% of cases).

Molecular Methods

- PCR available targeting *M. pneumoniae* specific 16S rRNA gene and P1adhesin gene.
- Multiplex PCR has been developed detecting the common agents of atypical pneumonia—*M. pneumoniae, Chlamydophila pneumoniae* and *Legionella pneumophila*.
- Real-time PCR: It is useful for quantitative detection of *M. pneumoniae*.

TREATMENT — ***Mycoplasma pneumoniae***

- Macrolides are drug of choice (oral azithromycin, 500 mg on day 1, then 250 mg on days 2 to 5).
- Alternative drugs are as follows:
  - Doxycycline
  - Respiratory fluoroquinolones such as levofloxacin, moxifloxacin and gemifloxacin (not ciprofloxacin).

UROGENITAL MYCOPLASMAS

M. hominis, M. genitalium, Ureaplasma (U. urealyticum, and U. parvum) are associated with urogenital tract disease.

- They frequently colonize female lower urogenital tract such as vagina, periurethral area and cervix.
- Transmission: They are transmitted mostly by sexual contact or mother to fetus during birth.

Clinical Manifestations

The manifestations of urogenital mycoplasmas are as follows:

- Non-gonococcal urethritis and epididymitis (mainly due to *Ureaplasma* and *M. genitalium*).
- Pyelonephritis (*M. hominis*), and urinary calculi (*Ureaplasma*)
- Pelvic inflammatory disease (mainly due to *M. hominis*)
- Postpartum and postabortal infection.
- Non-urogenital infections (rare, due to *M. hominis*) such as: Brain abscess, wound infections or neonatal meningitis.

Laboratory Diagnosis

Culture and PCR are the appropriate methods for diagnosis of urogenital mycoplasmas. *Ureaplasma* forms very tiny colonies of 15–50 μm size, hence it was previously named as T-form *Mycoplasma*.

TREATMENT — ***Mycoplasma pneumoniae***

- Macrolides (azithormycin) are the drug of choice for *Ureaplasma* and *M. genitalium* infections.
- Doxycydline is the drug of choice for *M. hominis*.
- However, resistance has been reported to both the drugs.

EXPECTED QUESTIONS

I. Write short notes on:

1. Primary atypical pneumonia
2. Comparison of *Mycoplasma* and L-forms

II. Multiple Choice Questions (MCQs):

1. Which is not a property of *Mycoplasma*?
   a. Susceptibility to beta lactams
   b. Have both DNA and RNA
   c. Can grow in cell-free media
   d. Extracellular survival

2. The agent of primary atypical pneumonia is?
   a. *Legionella pneumophila*
   b. *Klebsiella pneumoniae*
   c. *Mycoplasma pneumoniae*
   d. *Streptococcus pneumoniae*

3. Fried egg colonies are produced by:
   a. *Bacillus cereus*
   b. *Haemophilus influenzae*
   c. *Neisseria subflava*
   d. *Mycoplasma pneumoniae*

Answers

1. a **2.** c **3.** d

CHAPTER 41

General Properties of Viruses

This Chapter covers the following aspects of viruses:

- Morphology of virus
- Nomenclature and classification
- Viral replication
- Viral genetics
- Virus host interactions
- Laboratory diagnosis of viral diseases
- Treatment of viral diseases
- Immunoprophylaxis for viral diseases

Viruses are the smallest unicellular organisms that are obligate intracellular. Viruses are the most primitive microorganisms infecting man. They differ from bacteria and other prokaryotes, as:

- They are obligate intracellular.
- They possess either DNA (deoxyribonucleic acid) or RNA (ribonucleic acid), but never both.
- Filterable: They are smaller than bacteria, can be passed through the bacterial filters.
- They cannot be grown on artificial cell free media (However, they can grow in experimental animals, embryonated eggs or tissue culture).
- They multiply by a complex method, but not by binary fission as seen in bacteria.
- Viruses do not have a proper cellular organization.
- They do not have cell wall or cell membrane or cellular organelles including ribosomes.
- They lack the enzymes necessary for protein and nucleic acid synthesis.
- They are not susceptible to antibacterial antibiotics.

MORPHOLOGY OF VIRUS

Viruses possess a **nucleic acid** (DNA or RNA) surrounded by a protein coat called as **capsid**, together known as the nucleocapsid. Some viruses also have an outer **envelope** (Fig. 41.1).

Nucleic Acid

Viruses have only one type of nucleic acid, either DNA or RNA but never both. Accordingly, they are classified as DNA viruses and RNA viruses. The nucleic acid may be single or double stranded, circular or linear, segmented or unsegmented.

Capsid

Capsid is composed of a number of repeated protein subunits (polypeptides) called capsomeres. Functions of capsid includes:

- It protects the nucleic acid core from the external environment.
- In non-enveloped viruses, it initiates the first step of viral replication by attaching to specific receptors on the host cells,thus facilitating the entry of the virus.
- It is antigenic and specific for each virus.

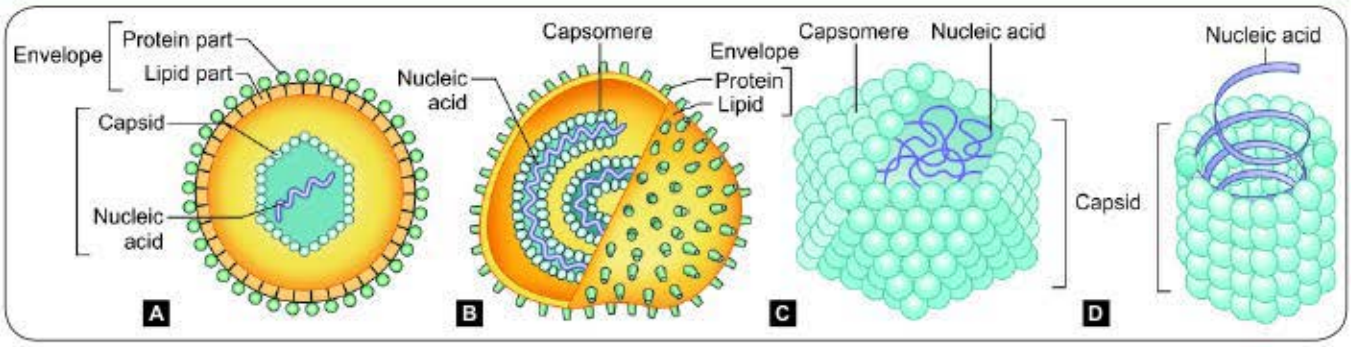
Symmetry

Depending upon the arrangement of capsomeres surrounding the nucleic acid, three types of symmetries are described.

1. **Icosahedral (cubical) symmetry:** The capsomeres are arranged as if they lay on the faces of an icosahedron which has 20 triangular facets and 12 corners or vertices. Such viruses have a rigid structure. Viruses that are smaller than 50 nm may appear spherical under electron microscope. All DNA viruses (except poxviruses) and most of the RNA viruses have icosahedral symmetry (Figs 41.1A and C).
2. **Helical symmetry:** The capsomeres are coiled surrounding the nucleic acid in the form of a helix or spiral. Such viruses are often flexible. Example include few RNA viruses such as—myxoviruses, rhabdoviruses, filoviruses, bunyaviruses, etc. (Figs 41.1B and D).
3. **Complex symmetry:** Poxviruses donot have either of the above symmetry, but they possess a complex symmetry.

Envelope

Certain viruses possess an envelope surrounding the nucleocapsid. Envelope is lipoprotein in nature.



Figs 41.1A to D: Structure and symmetry of virus. **A.** Enveloped virus with icosahedral nucleocapsid; **B.** Enveloped virus with helical nucleocapsid; **C.** Non-enveloped virus with icosahedral nucleocapsid; **D.** Non-enveloped virus with helical nucleocapsid

- The lipid part is derived from the host cell membrane and the protein part is virus coded, made up of subunits called **peplomers,** which project as spikes on the surface of the envelope.
- Some viruses may have more than one kind of peplomers, e.g. Influenza viruses possess hemagglutinin and neuraminidase peplomers.
- Enveloped viruses are more susceptible to heat and lipid solvents like ether.
- Peplomers are antigenic. They can also bind to specific receptors on the host cells, thus facilitating the entry of the virus.
- **Example:** See box

Most Viruses are Enveloped Except

- Non-enveloped DNA viruses—parvovirus, adenovirus and papovavirus.
- Non-enveloped RNA viruses—picornavirus, hepatitis A virus and hepatitis E virus.

Size of the Viruses

Viruses are extremely small, vary from 20-400 nm in size. Smallest virus is parvovirus (20 nm) and largest being poxvirus (400 nm).

- Because of the small size, viruses can pass through bacterial filters and they cannot be visualized under light microscope.
- **Size of the viruses** (Fig. 41.2) can be determined by:
  - Electron microscope (best method).
  - Ultracentrifugation: Viral particles suspended in liquid medium when subjected to ultracentrifugation, will settle down at a sedimentation rate that is proportional to their size.
  - Passage through membrane filters of different pore sizes: The maximum pore size that prevents a virus to pass through multiplied by 0.64 yields the approximate diameter of the viral particle.

Shapes of the Viruses

Most of the animal viruses are **roughly spherical** with some exceptions.

Shapes of the Viruses

- **Rabies virus:** Bullet shaped
- **Ebola virus:** Filamentous shaped
- **Poxvirus:** Brick shaped
- **Adenovirus:** Space vehicle shaped

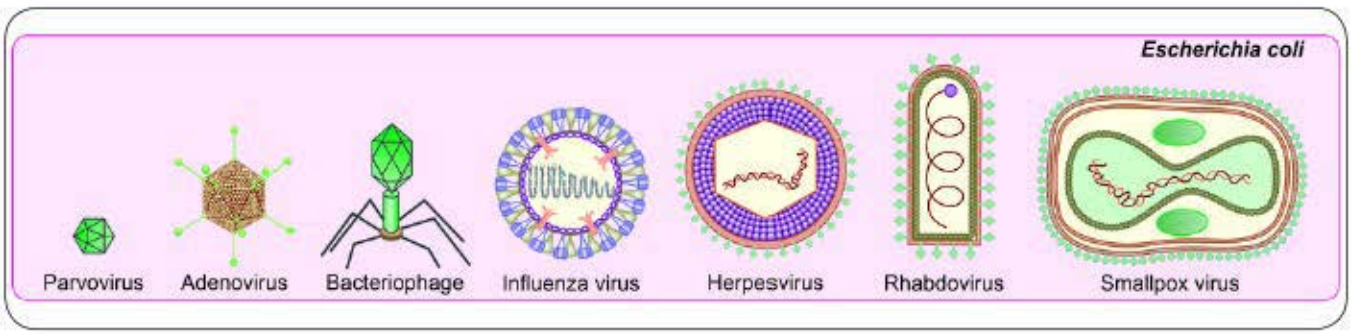


Fig. 41.2: Comparison of sizes of various viruses with that of *Escherichia coli*

Viruses Differ from Viroids, Prions and Virusoids

- **Viroids** comprise of naked, cyclical, small ssRNA without a capsid. They are mostly restricted to plants. They depend on host enzymes for replication (Described in Chapter 49).
- **Prions** consist of abnormal infectious protein molecules without nucleic acid.
  - They are highly resistant to physical and chemical agents.
  - Prions produce slow infections in humans having long incubation period (in years) called prion disease (a neurodegenerative condition of brain).
- **Virusoids** are plant pathogens similar to viroids, made up of circular RNA without protein, but are dependent on other plant viruses for replication and encapsidation.

NOMENCLATURE AND CLASSIFICATION

International Committee on Taxonomy of Viruses (2000) had proposed a classification for viruses (Table 41.1).

- Viruses are grouped into families (ending with suffix '*viridae*') on the basis of morphology, genome structure, and strategies of replication.
- Viruses infecting humans belong to 24 families, out of which important ones are depicted below (Table 41.1).
- Most of the families are further classified into genera (ending with suffix –'*virus*') based on physicochemical or serologic differences.
- Some families (Poxviridae, Herpesviridae, Parvoviridae and Paramyxoviridae) have subfamilies, which in turn consist of genera.

TABLE 41.1: Classification of viruses

Family	Nucleic acid	Envelope	Symmetry	Size (nm)	Representative Viruses
DNA Viruses	**DNA**				
herpesviridae	ds, linear	Yes	Icosahedron	150–200	▪ Herpes simplex virus (HSV)-1 ▪ Herpes simplex virus (HSV)-2 ▪ Varicella-zoster virus ▪ Epstein-Barr virus (EBV) ▪ Cytomegalovirus (CMV) ▪ Human herpesvirus 6, 7 and 8
Hepadnaviridae	ds, circular, incomplete	Yes	Icosahedron	40–48	▪ Hepatitis B virus
Parvoviridae	ss, linear	Absent	Icosahedron	18–26	▪ Parvovirus B19
Papovaviridae	ds, circular	Absent	Icosahedron	45–55	▪ Human papillomavirus ▪ JC virus and BK virus
Poxviridae	ds, linear	Yes	Complex	230 x 400	▪ Variola (smallpox) ▪ Molluscum contagiosum virus
Adenoviridae	ds, linear	Absent	Icosahedron	70–90	▪ Human adenovirus
RNA Viruses	**RNA**				
Picornaviridae	ss, +ve sense	Absent	Icosahedron	28–30	▪ Poliovirus ▪ Coxsackievirus ▪ Echovirus ▪ Enterovirus ▪ Rhinovirus ▪ Hepatitis A virus
Caliciviridae	ss, +ve sense	Absent	Icosahedral	27–40	▪ Norwalk agent ▪ Hepatitis E virus
Togaviridae	ss, +ve sense	Yes	Icosahedral	50–70	▪ Rubella virus ▪ Eastern equine encephalitis virus ▪ Western equine encephalitis virus
Flaviviridae	ss, +ve sense	Yes	Icosahedral*	40–60	▪ Yellow fever virus ▪ Dengue virus ▪ St. Louis encephalitis virus ▪ West Nile virus ▪ Hepatitis C virus
Coronaviridae	ss, +ve sense	Yes	Helical	120–160	▪ Coronaviruses

Contd...

Contd...

Family	Nucleic acid	Envelope	Symmetry	Size (nm)	Representative Viruses
RNA Viruses	**RNA**				
Rhabdoviridae	ss, -ve sense	Yes	Helical	75 x 180	▪ Rabies virus ▪ Vesicular stomatitis virus
Filoviridae	ss, -ve sense	Yes	Helical	80 x 1000	▪ Marburg virus ▪ Ebola virus
Paramyxoviridae	ss, -ve sense	Yes	Helical	150–300	▪ Parainfluenza virus ▪ Mumps virus ▪ Measles virus ▪ Respiratory syncytial virus (RSV) ▪ Newcastle disease virus ▪ Metapneumovirus
Orthomyxoviridae	ss, -ve sense, 8 segments	Yes	Helical	80–120	▪ Influenza viruses- A, B, and C
Bunyaviridae	ss, -ve sense, 3 circular segments	Yes	Helical	80–120	▪ Hantavirus ▪ California encephalitis virus ▪ Sandfly fever virus
Arenaviridae	ss, -ve sense 2 circular segments	Yes	Helical*	50–300	▪ Lymphocytic choriomeningitis virus ▪ Lassa fever virus ▪ South American hemorrhagic fever virus
Reoviridae	ds, 10–12 segments	Absent	Icosahedral	60–80	▪ Rotavirus ▪ Reovirus ▪ Colorado tick fever virus
Retroviridae	Two identical copies of +ve sense ss RNA	Yes	Icosahedral (spherical)	80–110	▪ HTLV (Human T Lymphotropic virus) ▪ HIV (Human immunodeficiency virus)

*Doubtful

Abbreviations: DNA, deoxyribonucleic acid; RNA, ribonucleic acid; ds, double stranded; SS, single stranded; +ve, positive; –ve negative.

VIRAL REPLICATION

Viruses do not undergo binary fission (seen in bacteria), but undergo a complex way of cell division. Replication of viruses passes through six sequential steps:

Attachment → Penetration → Uncoating → Biosynthesis
Assembly → Maturation → Release

Adsorption/Attachment

It is the first and the most specific step of viral replication. It involves receptor interactions. The viruses have attachment sites on their envelopes or capsid proteins that bind to the complementary receptor sites present on the host cell surface.

- **HIV:** Viral surface glycoprotein gp 120 binds to CD4 molecules on the host cells.
- **Influenza:** Viral hemagglutinin (an envelope protein) binds specifically to glycoprotein receptors present on the surface of respiratory epithelium.

Penetration

After attachment, the virus particles penetrate into the host cells either by—

- **Phagocytosis (or viropexis):** It occurs through receptor mediated endocytosis resulting in the uptake of virus particles within the endosomes of the host cytoplasm.
- **Membrane fusion:** Some enveloped viruses (e.g. human immunodeficiency virus or HIV) enter by fusion of their envelope proteins with the plasma membrane of the host cell so that only the nucleocapsid enters into the cytoplasm, whereas the viral envelope remains attached to the host cell membrane.
- **Injection of nucleic acid:** Bacteriophages (viruses that infect bacteria) cannot penetrate the rigid bacterial cell wall, hence only the nucleic acid is injected; while the capsid remains attached to the cell wall.

Uncoating

By the action of lysosomal enzymes of the host cells, the viral capsid gets separated and the nucleic acid is released into the cytoplasm. This step is absent for bacteriophages.

Biosynthesis

In this step, the following viral components are synthesized:

- Nucleic acid
- Capsid protein
- Enzymes required for various stages of viral replication.
- Regulatory proteins to shut down the host cell metabolism.

Site of Nucleic Acid Replication

- In DNA viruses, the DNA replication occurs in the nucleus except in poxviruses, which synthesize DNA in the cytoplasm.
- In RNA viruses, the RNA replication occurs in cytoplasm except in retroviruses and orthomyxoviruses, which synthesize RNA in the nucleus.

DNA Viruses

Biosynthesis of DNA viruses involves the following basic steps (Fig. 41.3):

- Transcription of parental DNA to form early messenger RNA (mRNA).
- Early mRNA undergoes translation to produce early non-structural proteins.
- **Viral DNA replication:** Early non-structural proteins shutdown the host metabolism and help in the replication of parental DNA to form copies of progeny DNA.
- Progeny DNA undergoes transcription to form late mRNA, which are further translated to form late structural proteins (i.e. capsids and envelope proteins).

Minor Differences in Replication Among DNA Viruses

- **Site:** DNA replication occurs in nucleus (except in poxviruses), whereas the mRNA transcription and protein translation take place in the cytoplasm.

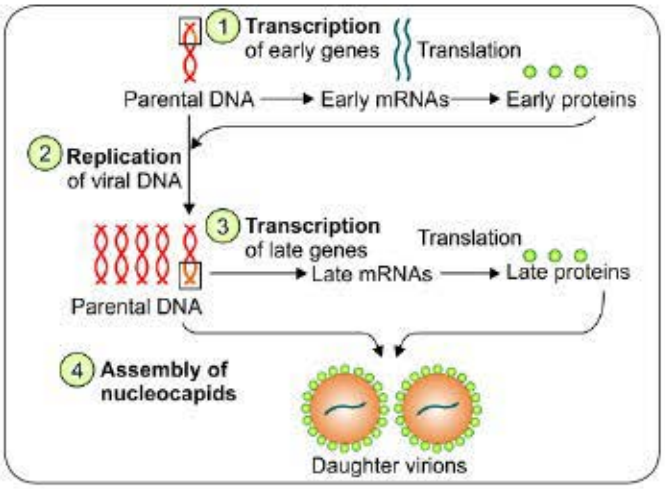

Fig. 41.3: Steps of DNA virus biosynthesis

- Most DNA viruses use host enzymes for transcription, except poxviruses which use their own viral enzymes.
- The linear dsDNA of herpesviruses becomes circular inside the host cell and then replicates by **rolling circle mechanism**. However, DNA of other viruses remain either linear or circular as they are inside the viruses (i.e. adenoviruses, poxviruses, parvoviruses have linear DNA and papovaviruses and hepadnaviruses have circular DNA).
- Hepadnaviruses (e.g. Hepatitis B virus) contain partially dsDNA that is first converted to fully dsDNA by viral polymerases. Then the dsDNA undergoes transcription to produce mRNA and a pregenomic RNA. DNA doesnot directly undergo replication but the progeny DNA are formed by reverse transcription of pregenomic RNA (Discussed in detail in Chapter 50).
- **Parvoviruses** have a negative sense ssDNA, which first gets duplexed to form dsDNA using host enzymes. Then the remaining steps are the same.

RNA Viruses

The process of biosynthesis varies among RNA viruses depending whether the genomic RNA is positive/negative sense and single/double stranded.

Type I (Positive Sense Single Stranded RNA Viruses)

They have an RNA with same polarity as mRNA, hence they can directly translate to form early proteins (Fig. 41.4A).

- **Synthesis of progeny RNA:** Early proteins have RNA polymerase activity that direct replication of (+)ssRNA → (–) ssRNA → (+) ssRNA
- Late proteins are formed by translation of (+)ssRNA.

Type II (Negative Sense Single Stranded RNA Viruses)

Their RNA polarity is opposite to that of mRNA, hence they cannot directly translate into proteins (Fig. 41.4B).

- The (–) ssRNA transforms to (+) ssRNA first, using viral RNA polymerases.
- Then the (+)ssRNA translates to form proteins and also it acts as template and undergoes replication to form copies of (–)ssRNA.

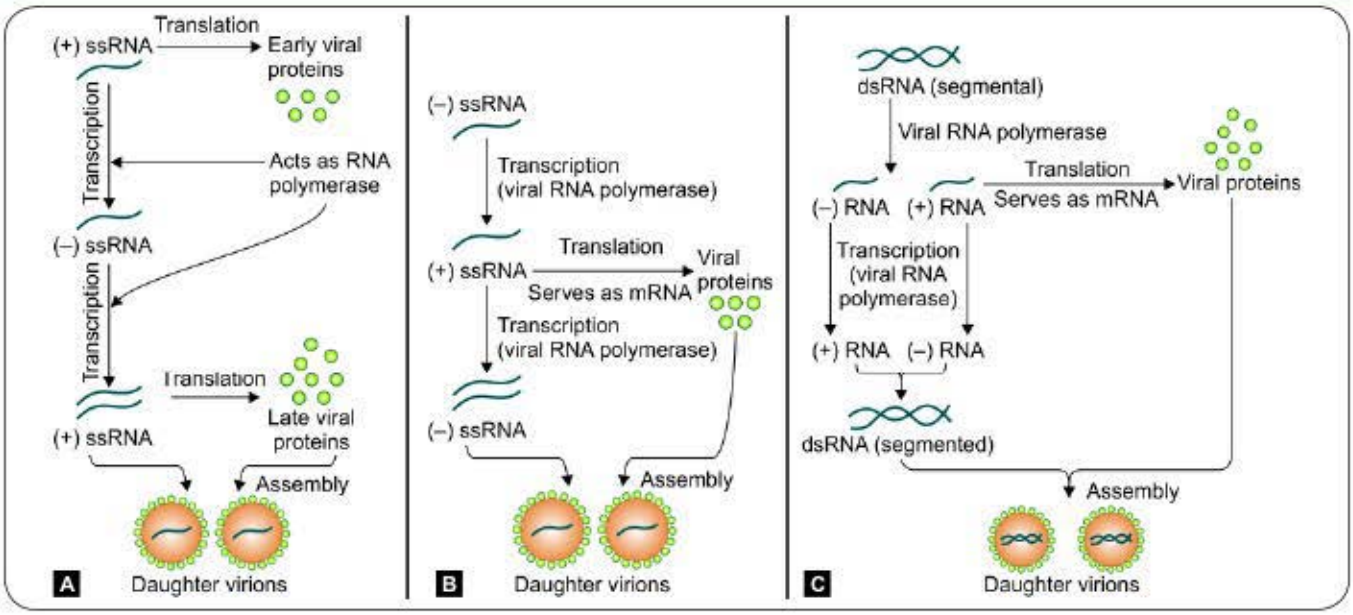
Type III (Double Stranded RNA Viruses)

Reoviruses have dsRNA which is usually segmented with each segment coding for one polypeptide (Fig 41.4C).

- The (+) strand RNA can act as mRNA and transcribes proteins by using viral enzymes.
- Both the (+) and (–) strands serve as templates for the synthesis of complementary strands to form the duplex.

Type IV (Retrovirueses)

HIV and other retroviruses possess two copies of linear non segmented (+)ssRNA and enzymes such as reverse transcriptase (RT) and integrase (Fig 41.5).



Figs 41.4A to C: Replication of—**A.** Positive sense ss RNA virus; **B.** Negative sense ss RNA virus; **C.** ds RNA virus

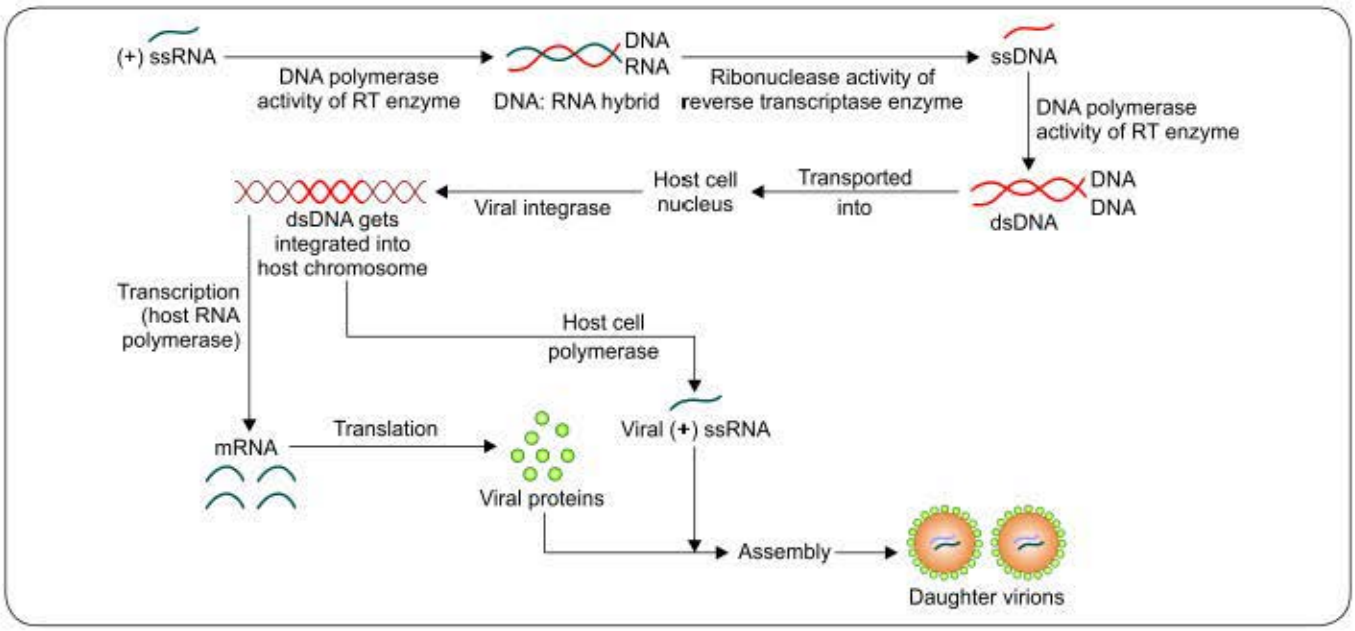


Fig. 41.5: Replication retroviruses (e.g. HIV)

- After entry into the host cell, the ssRNA gets reverse transcribed to form ssDNA by viral RT which acts as RNA dependent DNA polymease. DNA:RNA hybrid is formed.
- Reverse transcriptase has also ribonulcease activity by which it digests the RNA from DNA:RNA hybrid.
- The resulting ssDNA is converted to dsDNA by the DNA polymerase activity of the same RT enzyme.
- dsDNA is transported to the nucleus where it gets integrated into the host chromosome by viral integrase.
- The integrated DNA serves as template for production of mRNA (which are translated into proteins) and genomic progeny RNA.

Assembly

Viral nucleic acid and proteins are packaged together to form progeny viruses (nucleocapsids). Assembly may take place in the host cell nucleus or cytoplasm.

- DNA viruses are assembled in the nucleus except hepadnaviruses and poxviruses (in cytoplasm).
- RNA viruses are assembled in the cytoplasm.

Maturation

Following assembly, maturation of daughter virions take place either in the host cell nucleus or cytoplasm or membranes (Golgi or endoplasmic reticulum or plasma membrane).

Release

Release of daughter virions occur either by:

- **Lysis of the host cells:** As shown by non enveloped viruses and bacteriophages.
- **Budding through host cell membrane:** As shown by enveloped viruses—during budding, they acquire a part of the host cell membrane to form the lipid part of their envelopes.
- Envelope is acquired either from plasma membrane (influenza virus) or from nuclear membrane (e.g. herpesviruses).
- Viral glycoproteins are then inserted into the envelopes.
- Excess viral glycoproteins are synthesized to saturate cell receptors so that the viruses will not stick to the host cell following release.

Eclipse phase: It is defined as 'interval between the penetration of the virus into the host cell till the appearance of first infectious virus progeny particle.'

- During this period, the virus cannot be demonstrated inside the host cell.
- The duration of eclipse phase is about 15 to 30 minutes for bacteriophages and 15–30 hours for most of the animal viruses.

Abnormal Replicative Cycles

Incomplete Viruses

These are formed as a result of defective assembly where the proteins are assembled without nucleic acid. These viruses are not infective. Such a defective assembly in influenza virus leads to production of progency viral particles having high hemagglutinin titer but low infectivity; which is known as **Von Magnus phenomenon**.

Pseudovirions

The capsid occasionally encloses the host cell nucleic acid instead of viral nucleic acid. Such pseudovirions are noninfective and cannot replicate.

Abortive Infection

It occurs when viruses enter into wrong host cells (non permissive cells). Here, the parent virus is normal, but still does not perform some of the steps of viral replication.

Defective Viruses (Dependoviruses)

Such viruses are genetically defective. They cannot perform all the steps of viral replication by themselves, but they need a second helper virus, which can supplement the genetic deficiency. Examples of defective viruses are-

- Hepatitis D virus (requires the help of hepatitis B virus).
- Adeno-associated satellite viruses (require the help of adenoviruses).

Defective Interfering Particles

These viruses lack a portion of their genome (due to deletion mutation), but contain normal capsid protein. They require infectious homologous normal virus as helper for replication, and they in contrast to the defective viruses, may interfere with the replication of the helper virus.

VIRAL GENETIC MODIFICATIONS

Similar to other living objects, viruses also follow laws of genetics. Several properties of viruses (e.g. virulence, antigenicity, capsid production) are under genetic control. The viruses show genetic modifications by two principal methods—(1) mutations and (2) interactions between viral genes or their gene products (proteins).

Mutation

Mutations occur during every viral infection, at a frequency of 10^{-4} to 10^{-8} mutations per base pair per generation. However, mutation becomes evident only if it induces some readily observable property or leads to survival or death of the virus.

- Mutants occur spontaneously or may be induced chemically (e.g. 5-fluorouracil) or by physical agents such as UV light or irradiation.
- **Types of mutations:** The mutants may be of various types as described in bacteria (Chapter 6). A special class of mutant is seen among viruses called **conditional lethal mutant** which has great applications in virology.

> **Conditional lethal mutant** can grow only in specific conditions called permissive conditions, but cannot grow in other conditions.
>
> **Temperature sensitive mutant** (*ts* mutant) is a type of conditional lethal mutant that can grow at a low (permissive) temperature (28-31°C), but not at higher (restrictive) temperature (37°C). *ts* mutants have been used for preparation of live viral vaccines (e.g. *ts* influenza vaccine).

Interactions Between Viral Genes

When two or more virus particles infect the same host cell, there occurs a variety of both genetic and non-genetic interactions.

Genetic Recombination

It occurs between two different but related viruses of the same family infecting a host cell simultaneously.

- The two viruses exchange segments of nucleic acids between them so that a hybrid (recombinant virus) results.
- Such hybrids possess new genes not found in both the parent viruses, are genetically stable and able to replicate.

Reassortment

It is a type of recombination seen in segmented RNA viruses such as influenza, rota, bunya, and arena viruses.

- When two strains of influenza virus infect a host cell, gene exchanges take place between the RNA segments resulting in production of reassortants.
- Reassortment is probably the most important method by which the pandemic strains of the influenza virus originate in nature (e.g. H1N1 strain in 2009).

Genetic Reactivation

It can occur in two ways:

1. Marker Rescue

It occurs when a host cell is infected with an active virus and a different but related inactive virus simultaneously. A portion of the genome of the inactivated virus combines with that of the active virus, so that certain markers of the inactivated virus are rescued and the progeny viruses appear viable.

Example: The epidemic strains of influenza (which usually do not grow in eggs) when mixed with inactivated standard laboratory stains, the resultant progeny carry the virulence property of epidemic strain but growth characteristics of laboratory strain, hence can be grown in eggs.

2. Multiplicity Reactivation

It occurs when many inactive viruses interact in the same host cell to produce a stable viable virus.

Example: This usually occurs when viruses are inactivated by UV rays (e.g. UV irradiated vaccines). Such inactivated viruses have damages in different genes. Thus, from the total genetic pool, the healthy genes may get combined to form a complete undamaged genome. Therefore, UV irradiation is no longer recommended for producing inactivated viral vaccines.

Interactions Between Viral Gene Products

- **Phenotypic mixing:** It occurs when the genome of one virus is assembled within capsid of a different but related virus or a capsid consisting of components of both the viruses. The former is called as **phenotypic masking or transcapsidation**.
  - Such progeny are not genetically stable.
  - Upon subsequent replication, they lose the capsids and acquire their own capsids.
- **Pseudotype formation:** It is a type of phenotypic mixing that occurs between enveloped viruses.
  - The nucleocapsid of one virus gets surrounded by an envelope of another virus.
  - This phenomenon may occur even between unrelated viruses, usually observed between RNA tumor viruses, e.g. vesicular stomatitis virus.
- **Genotypic mixing:** This occurs when multiple complete genomes are accidentally surrounded by a single virus capsid. It is not a stable genetic change.
- **Complementation:** When a host cell is infected with two viruses, one or both of which may be defective; they complement each other's replication by providing gene products (proteins) in which the other one is deficient.

Viral Interference

Viral Interference is another important example of interaction between viruses (see below in the box).

Viral Interference

When two viruses infect a host cell or a cell line, sometimes it leads to inhibition of one of the virus. Interference does not occur with all viral combinations; many viruses may infect and multiply together in a host cell.

Several mechanisms may be responsible for viral interference:

- First virus may inhibit the entry of second virus either by:
  - Blocking the host cell receptors- e.g. retroviruses, enteroviruses or
  - Destroying the host cell receptors-e.g. Influenza virus by producing neuraminidase
- First virus may compete with the second for components needed for replication apparatus (e.g. polymerase)
- The first virus may induce the host cell to produce interferon which prevents replication of the second virus.

Interference and Oral Polio Vaccine (OPV)

Viral interference is classically observed with OPV which contains three live attenuated serotypes of poliovirus.

- OPV serotypes interfere with the spread of wild poliovirus thus played a crucial role in control of the polio outbreaks.
- On the other hand, interference in between the three OPV serotypes or interference by pre-existing enteric viruses with OPV serotypes may result in vaccine failure.

VIRUS HOST INTERACTIONS

PATHOGENESIS OF VIRAL INFECTIONS

Most of the viral infections progress through the following steps inside the human body.

- Transmission (entry into the body)

TABLE 41.2: Transmission and spread of viruses

Mode of transmission	Produce local infection at the portal of entry	Spread to distant sites from the portal of entry
Respiratory route (probably the most common route)	**Produce respiratory infection** ▪ Influenza virus ▪ Parainfluenza virus ▪ Respiratory syncytial virus (RSV) ▪ Rhinovirus ▪ Adenovirus ▪ Coronavirus ▪ Herpes simplex virus (HSV)	• Measles virus ▪ Mumps virus ▪ Rubella virus ▪ Varicella-zoster virus ▪ Cytomegalovirus (CMV) ▪ Parvovirus ▪ Smallpox virus
Oral route	**Produce gastroenteritis** ▪ Rotavirus ▪ Adenovirus-40,41 ▪ Calicivirus ▪ Astrovirus	▪ Poliovirus ▪ Coxsackie virus ▪ Hepatitis virus – A and E ▪ Cytomegalovirus ▪ Epstein-Barr virus (EBV)
Cutaneous route	**Produce skin lesions** ▪ Herpes simplex virus (HSV) ▪ Human papillomavirus (HPV) ▪ Molluscum contagiosum virus	▪ Herpes simplex virus
Vector bite	–	Arboviruses such as: ▪ Dengue virus (*Aedes*) ▪ Chikungunya virus (*Aedes*) ▪ Japanese encephalitis virus (*Culex*) ▪ Yellow fever virus (*Aedes*) ▪ Kyasanur Forest disease virus (Tick)
Animal bite	–	▪ Rabies virus
Sexual route	**Produce genital lesions** ▪ Herpes simplex virus (HSV) ▪ Human papillomavirus (HPV)	▪ Hepatitis B, C and rarely D viruses ▪ Human immunodeficiency virus (HIV)
Blood transfusion	–	▪ Hepatitis B, C and rarely D viruses ▪ HIV ▪ Parvovirus
Injection	–	▪ Hepatitis B, C and rarely D viruses ▪ HIV
Transplacental route	**Produce congenital manifestations in fetus** ▪ Rubella virus ▪ Cytomegalovirus ▪ Herpes simplex virus ▪ Varicella-zoster virus ▪ Parvovirus	**Transmitted through placenta to fetus, without congenital manifestations** ▪ Measles virus ▪ Mumps virus ▪ Hepatitis B, C and rarely D viruses ▪ HIV
Conjunctival route	▪ Adenovirus ▪ Enterovirus 70 ▪ Coxsackie virus A-24 ▪ Herpes simplex virus	–

- Primary site replication
- Spread to secondary site
- Manifestations of the disease

Transmission

Viruses enter into the human body through various routes (Table 41.2).

Primary Site of Replication

- Some viruses are restricted to the portal of entry where they multiply and produce local diseases. They spread locally over the epithelial surfaces, but there is no viremia or spread to distant sites. They have a shorter incubation period and shorter duration of immunity.

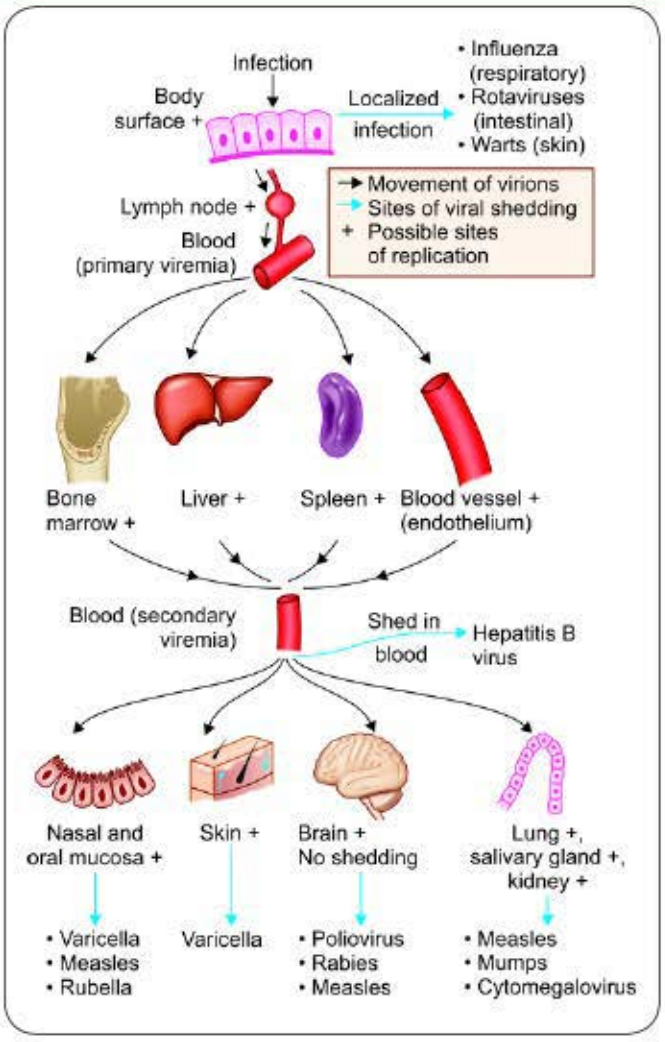

Fig. 41.6: Pathogenesis of viral infections

- On the other hand, most viruses multiply locally to initiate a silent local infection, which is followed by the spread via lymphatics to regional lymph nodes (most viruses) or via blood (e.g. poliovirus) or via neuronal spread to reach CNS (e.g. rabies virus).

Spread of Virus (Fig. 41.6)

- **Primary viremia:** Viruses spread to the blood stream either from the primary sites or from the lymph nodes. In blood, viruses may remain as free in plasma or may be cell-associated in lymphocytes or macrophages.
- **Secondary site replication:** Viruses are then transported to the reticulo endothelial system (bone marrow, endothelial cells, spleen and liver) where further multiplication takes place. Secondary sites are called as the central foci for viral multiplication.
- **Secondary viremia:** From the spleen and liver, viruses spillover into the blood stream leading to *secondary viremia* which result in the onset of non-specific symptoms.
- **Target organs:** Via the blood stream, they reach the target organs (lung, brain, skin, etc.). Certain viruses (e.g. rabies) affecting brain, there is no viremia. Instead, virus reaches the target organ via neuronal spread.
- **Tropism** of the viruses for specific organs (Table 41.3) determines the pattern of systemic illness (e.g. hepatitis viruses have tropism for hepatocytes, and produce hepatitis as the primary disease). Tropism in turn depends on the presence of host cell receptors specific for the viruses.

TABLE 41.3: Cell tropism of human viruses

Cell type associated	DNA Viruses	RNA Viruses
Lymphocytes	▪ Epstein-Barr virus ▪ Cytomegalovirus ▪ Hepatitis B virus ▪ JC virus ▪ BK virus	▪ Mumps ▪ Measles ▪ Rubella ▪ HIV
Monocytes-macrophages	Cytomegalovirus	▪ Poliovirus ▪ HIV ▪ Measles
Neutrophils	–	▪ Influenza virus
Red blood cells	Parvovirus B19	▪ Colorado tick fever virus
None (free in plasma)	–	▪ Togavirus ▪ Picornavirus

Virus Shedding

Shedding of infectious virus is a necessary step to maintain viruses in the environment or hosts. Shedding may occur at various stages of disease.

- **Portal of entry** is the site for shedding for those viruses that produce local infection, e.g. influenza virus is shed in respiratory secretions.
- **Blood:** The viruses that spread through vector bite (arboviruses) or by blood transfusion or needle pricks (hepatitis B) are shed in blood.
- **Near the target tissue/organ:** Skin (Varicella-zoster), salivary gland (mumps), kidney (CMV).
- **No viral shedding:** Humans are the dead end for certain viruses infecting central nervous system, such as rabies.

Manifestations of Viral Infections

Incubation Period

The incubation period is the time interval between entry of the virus into the body and appearance of first clinical manifesation. Therefore, incubation period depends on the distance between site of entry and the target organ.

- It is shorter if the virus produces lesions near to the site of entry, e.g. influenza virus.
- It is longer if the target organ is much far from the site of entry, e.g. poliovirus and rabies virus.
- **Exception:** There are many exceptions to this rule. For, e.g. both dengue and hepatitis B virus are blood borne, but they greatly vary in incubation periods (4–5 days and 30–180 days respectively).

There are many other factors that depends on the incubation period such as host immune response, nature of the virus etc.

Depending on the clinical outcome, viral infections can be categorized into:

- Inapparent (subclinical) or
- Apparent (clinical or overt) infections which may be acute, subacute or chronic infection.
- Latent or persistent infections (described later)

VIRAL PATHOGENESIS AT THE CELLULAR LEVEL

At the cellular level, the virus can produce three types of infections in a host cell which in turn depends on the nature of the virus and the cell infected.

Failed infection (Abortive Infection)

It occurs if the virus infects the host cells which are non permissive (i.e. absence of surface receptors or machineries to support viral replication)

Cell death (Cytocidal or Lytic Infection)

Viruses adopt different mechanisms to induce host cell death such as:

- Inhibition of host cell DNA by herpesvirus
- Inhibition of host cell protein synthesis by poliovirus
- **Fusion (syncytia formation):** Glycoproteins of some enveloped viruses (paramyxoviruses, herpesviruses, and retroviruses) are expressed on host cell surface which triggers the fusion of neighboring cells to form multinucleated giant cells called syncytia, that allows the virus to spread from cell to cell and escapes antibody neutralization.
- Disruption of cytoskeleton by non-enveloped viruses and herpesvirus.
- Immune mediated lysis: The expression of viral antigens on the host cell surface can lead to binding of antibodies followed by complement or natural killer (NK) cell mediated lysis.
- Inducing apoptosis of the host cells.
- Release of progeny viruses by lysis of the host cells (e.g.poliovirus).

Infection without Cell Death

This may be of two types:

Steady State Infection

The virus and host cell enter into a peaceful coexistence, both replicating independently without any cellular injury.

Persistent Viral Infection

The virus undergoes a period of latency which may be of various types:

- **Latent infection with periodic exacerbations:** Seen with members of Herpesviridiae family.
- **Cell transformation:** Oncogenic viruses such as hepatitis B virus or Epstein-Barr virus or human papillomavirus induce host cell transformation and the transformed cells divide indefinitely leading to tumor production.
- **Latency in HIV infection:** Viral genome gets integrated with host cell chromosome and undergoes long period of clinical latency.
- **Latency in slow virus infection:** Slow viruses have an unsual long incubation period (years).
- **Persistent tolerant infection:** The classical example is lymphocytic choriomeningitis virus infecting mice. Here, the host is immunologically tolerant to the virus, does not show any immune response, but the virus is readily demonstrable in the tissues. Disease sets in when the tolerance is interrupted.

Morphological Changes in the Host Cells

Certain viruses induce characteristic changes in the formation of appearance and staining properties of the target cells which can be detected by histopathological staining.

- **Damage to the host cell chromosomes:** For example formation of chromatin rings surrounding the nuclear membrane in host cells infected with HSV or adenovirus.
- **Formation of inclusion body:** See box below and Table 41.4.

TABLE 41.4: Inclusion bodies

Intracytoplasmic inclusion bodies
▪ Negri bodies—seen in rabies virus ▪ Paschen body—seen in variola virus ▪ Guarnieri bodies—seen in vaccinia virus ▪ Bollinger bodies—seen in fowlpox virus ▪ Molluscum bodies—seen in molluscum contagiosum virus ▪ Perinuclear cytoplasmic body—seen in reovirus
Intranuclear inclusion bodies
Cowdry type A inclusions
▪ Torres body—seen in yellow fever virus ▪ Lipschultz body—seen in herpes simplex virus
Cowdry type B inclusions
▪ Poliovirus ▪ Adenovirus
Intracytoplasmic and intranuclear inclusion bodies
▪ Owl's eye appearance seen in cytomegalovirus ▪ Measles virus

Inclusion Body

They are the aggregates of virions or viral proteins and other products of viral replication that confer altered staining property to the host cell.

Role In Laboratory Diagnosis

Inclusion bodies are characteristic of specific viral infections. They have distinct size, shape, location and staining properties by which they can be demonstrated in virus infected cells under the light microscope.

Location

They may be present either in the host cell cytoplasm or nucleus or both (Table 41.4).

- **Intracytoplasmic inclusion bodies:** They are generally acidophilic and can be seen as pink structures when stained with Giemsa or eosin methylene blue stains (e.g. most poxviruses and rabies).
- **Intranuclear inclusion bodies:** They are basophilic in nature.Cowdry (1934) had classfied them into:
  - Cowdry type A inclusions: They are variable in size and have granular appearance.
  - Cowdry type B inclusions: They are more circumscribed and multiple.
- **Both intracytoplasmic and intranuclear inclusions.**

HOST IMMUNE RESPONSES

The outcome of viral infection is determined by several viral and host factors. Viral factors include inoculum size, virulence of the virus, serotype, and cytopathic effect of the virus. Host factors can be classified into nonspecific or specific immunological responses.

Non-Specific Immune Responses

- **Host immune status:** Low immunity predisposes to many viral infections, such as CMV. On the other hand, certain viral infections require an adequate host immune response (e.g. dengue).
- **Prior immunity to the virus:** Prior immunity to the virus due to vaccination or prior infection can protect the individual from further infection. Some viral infections such as smallpox, chickenpox, measles, mumps, and rubella provide lifelong immunity.
- **Permissiveness of host cells:** The host cell should bear the surface receptors or machineries required for viral replication.
- **Nutritional status:** Malnutrition lowers the host immunity and thus predisposes to many viral infections, e.g. measles. However, in certain viral infections such as dengue, malnutrition has a paradoxical effect.
- **Other comorbid diseases:** Presence of other comorbid diseases can influence the immune status of the individual and may predispose to viral infections.
- **Genetic makeup:** Certain individuals are more prone to develop some viral infections. This depends on the genetic makeup of the individual.
- **Age:** Most viral infections are common at extremes of age, i.e. childhood and old age. However, sexually transmitted viral infections are common among young adults.
- **Hormones:** Corticosteroids administration supresses the immunity, hence predisposes to most viral infections.
- **Body temperature:** Fever may act as a natural defence mechanism as most viruses are inhibited by temperature above 39°C. Exception is, febrile blisters seen in herpes infection.
- **Phagocytosis:** Macrophages play a crucial role in clearing of the viruses from the bloodstream. In contrast, neutrophils do not phagocytose viruses effectively.
- **Interferons:** See below

Interferons

Interferons (IFNs) are the cytokines, produced by host cells on induction by viral or nonviral inducers.

Classification

Interferons are classified into three groups, designated as IFN-α, β and γ (Table 41.5).

- IFN α and β are produced by many cell types and have antiviral action, hence called as type-I or viral interferons.
- IFN γ is produced mainly by lymphocytes, especially T cells and NK cells. It is not antiviral, but acts on macrophages and other immune cells, hence called as type-II or immune IFN.

Mechanism of Action

IFN has **no direct action** on viruses and it does not protect the virus-infected cell that produces it. However, it induces the other host cells to produce certain proteins called **translation inhibition proteins** (TIPs), that inhibit viral protein synthesis by selectively inhibiting the translation of viral mRNA, without affecting cellular mRNA. TIPs include:

- **Protein kinase:** Inactivates elongation factor-2 and thus prevents formation of the initiation complex needed for viral protein synthesis.
- **Oligonucleotide synthetase:** Activates endonuclease (RNase) which in turn degrades viral mRNA.
- **Phosphodiesterase:** Inhibits peptide chain elongation
- **Nitric oxide synthetase:** It is specifically induced by IFN-γ. It has no antiviral action, but acts on macrophages and other immune cells.

Interferons are Host Specific but not Virus Specific

- IFNs produced by one species can protect the cells of the same or related species only.

TABLE 41.5: Properties of interferons (IFNs)

Property	IFN-α	IFN-β	IFN-γ
Formerly called as	Leukocyte IFN	Fibroblast IFN	Immune IFN
Type of designation	Type I	Type I	Type II
Produced by host cell	Most cell types (mainly macrophages)	Most cell types (mainly by fibroblasts)	Lymphocytes (mainly T_H1 cells, rarely CD8 T cells, NK cells)
Inducing agent	Viruses; dsRNA	Viruses; dsRNA	Mitogens
Action	Antiviral action ↑MHC-I expression Activates NK cells Anti-proliferative function	Antiviral action ↑MHC-I expression Activates NK cells Anti-proliferative function	▪ Immunoregulatory function- ▪ Stimulates macrophages ↑MHC-I and II expression ▪ Anti-proliferative function
Stability at pH 2.0	Stable	Stable	Labile
Chromosomal location of genes	9	9	12
IFN receptor	IFN -α/β receptor	IFN -α/β receptor	IFN-γ receptor
IFN receptor genes located on chromosome number	21	21	6

Abbreviations: T_H, T helper; NK, natural killer cells, MHC, major histocompatibility complex

- IFNs induced by one virus (or even non-viral inducers) can be protective against the same or unrelated viruses. However, viruses vary in their susceptibility to interferon.

Inducers

Both viral and nonviral agents can induce IFN synthesis. Viruses vary in their capacity to induce IFNs.

- In general, RNA viruses and avirulent viruses are strong inducers of IFNs than DNA viruses or virulent (cytocidal) viruses.
- Examples of potent inducers are:
  - Viruses: Togaviruses, vesicular stomatitis virus, Sendai virus and NDV (Newcastle disease virus)
  - Nucleic acids (double-stranded RNA)
  - Synthetic polymers (e.g. Poly I:C)
  - Bacterial endotoxin
- IFN-γ production is not induced by viruses; It is induced by mitogen or antigen contact.

Quicker Induction

Interferon induction is much quicker than the antibody response. IFN synthesis begins within an hour of induction and reaches high levels in 6–12 hours.

Resistance

IFNs are proteins, hence they are inactivated by proteases, but not by nucleases or lipases. They are heat stable and also stable to wide ranges of pH (except IFN-γ which is labile at pH2).

Interferon Assay

Estimation of IFN level is based on their biological activity, such as ability to inhibit plaque formation by a sensitive virus. Being poorly antigenic, they cannot be detected serologically.

Preparations of Interferons

- **Human IFNs:** As IFNs are host specific, human IFNs prepared commercially by DNA recombinant technology are the best for human use.
- **Pegylated IFNs** are the IFN-α linked to polyethylene glycol. This linkage results in slower absorption, decreased clearance, and more sustained serum concentrations; hence they can be administered once a week.

Application

Interferons are used in the following clinical conditions:

- IFN-α is used:
  - Topically in rhinovirus infection, genital warts and herpetic keratitis.
  - Systemically-in chronic hepatitis B, C and D infections, hairy cell leukemia and Kaposi's sarcoma
- IFN-β is used in multiple sclerosis.
- IFN-γ is used in chronic granulomatous disease and osteopetrosis.

Specific Immunological Responses

In general, viral antigens are potent immunogens and can induce both cell-mediated immunity (CMI) and antibody-mediated immunity (AMI).

Cell-mediated Immune Response (CMI)

As viruses are intracellular, CMI plays a vital role to provide immunity against most viral infections. Viruses are processed by the host cells and the viral peptide antigens

are presented to the helper T cells. Following activation, helper T cells differentiate in to either T_H1 or T_H2 subtypes which in turn secrete specific cytokines that modulate the immune response to viral infections in the following ways:

- Activation of macrophages with enhanced phagocytic ability (mediated by IFN-γ secreted by T_H1 cells).
- Activation of cytotoxic (T_C) T cells (by IL-2 secreted by T_H1 cells)-T_C cells can cause lysis of virus infected cells by producing perforins and granzymes.
- Activation of NK cells by IL-2 secreted by T_H1 cells leads to cytotoxic killing of virus infected host cells
- Stimulation of B cells to produce antibodies (mainly by cytokines of T_H2 cells).

At times, CMI may contribute to the viral pathogenesis. In order to kill the viruses, T cells and NK cells also kill the virus-infected host cells thus may lead to tissue injury (e.g. liver injury seen during hepatitis virus infections)

Antibody-Mediated Immune Response

Antibodies are important in providing immunity against viral infection. However, antibodies cannot act when viruses are inside the host cells.

- IgG and IgM play a major role in blood and tissue spaces respectively.
- IgA acts at the mucosal surfaces and provides mucosal immunity by preventing the virus entry at local sites such as respiratory, intestinal and urogenital tracts.

Antibodies may act in the following ways:

- Neutralise viral surface antigens, thus preventing viral attachment to the host cells. However, it is important to note that antibodies cannot neutralize the internal antigens.
- Antibody may attach to viral antigens on the surface of infected cells, rendering these cells prone to:
  - Complement mediated lysis.
  - Destruction by phagocytes: Opsonisation of virus which in turn enhances phagocytosis by macrophages.
  - Natural killer cell mediated lysis (by antibody dependent cell mediated cytotoxicity or ADCC)

Even antibody-mediated immune response can work in the other way round:

- The non-neutralizing antibodies against dengue virus can facilitate subsequent dengue serotype infection by a peculiar phenomenon called as ADE (antibody-dependent enhancement).
- Antibodies can combine with viral antigens and cause immune complex mediated tissue injuries.

LABORATORY DIAGNOSIS OF VIRAL DISEASES

Laboratory diagnosis of viral infections is useful for the following purposes:

- **To start antiviral drugs** for those viral infections for which specific drugs are available such as herpes, CMV, HIV, influenza and respiratory syncytial virus (RSV).
- **Screening of blood donors** for HIV, hepatitis B and hepatitis C- helps in prevention of transfusion-transmitted infections.
- **Surveillance purpose:** To assess the disease burden in the community by calculating prevalence and incidence of viral infections.
- **For outbreak or epidemic investigation**, e.g. influenza epidemics, dengue outbreaks—to initiate appropriate control measures.
- **To start post exposure prophylaxis** of antiretroviral drugs to the health care workers following needle stick injury (Chapter 48).
- **To initiate certain measures:** For example:
  - If rubella is diagnosed in the first trimester of pregnancy, abortion is recommended.
  - If new born is diagnosed to have Hepatitis B infection, then immunoglobulins should be started within 12 hours of birth.

LABORATORY DIAGNOSIS — Viral Diseases

Direct Demonstration of Virus

- Electron microscopy
- Immunoelectron microscopy
- Fluorescent microscopy
- Light microscopy
  - Histopathological staining: To demonstrate inclusion bodies
  - Immunoperoxidase staining

Detection of viral antigens

By various formats such as ELISA, direct IF, ICT, flow through assays.

Detection of the Specific Antibodies

- Conventional techniques- such as HAI, neutralization test and CFT.
- Newer diagnostic formats such as ELISA, ICT, flow through assays.

Molecular Methods to Detect Viral Genes

- Nucleic acid probe–for detection of DNA or RNA by hybridization
- PCR- for DNA detection by amplification
- RT-PCR—for RNA detection
- Real time PCR—for DNA quantification
- Real time RT-PCR—for RNA quantification

Isolation of Virus by

- Animal inoculation
- Embryonated egg inoculation
- Tissue cultures: Organ culture, explant culture, cell line culture (primary, secondary and continuous cell lines).

DIRECT DEMONSTRATION OF VIRUS

Electron Microscopy

Detection of viruses by electron microscopy (EM) is increasingly used now a days. Specimens are negatively stained by potassium phosphotungstate and scanned under EM.

- **Shape:** Viruses can be identified based on their distinct appearances; for example:
  - Rabies virus—bullet shaped
  - Rotavirus—wheel shaped
  - Coronavirus—petal shaped peplomers
  - Adenovirus—space vehicle shaped
  - Astrovirus—star shaped peplomers
- **Direct detection from specimens:** For viruses that are difficult to cultivate, EM can be used as primary tool for diagnosis; for example:
  - Agents of viral gastroenteritis such as rotavirus, coronavirus, adenovirus, caliciviruses from diarrheal stool.
  - Hepatitis A and E viruses from feces.
  - Cytomegalovirus from urine (infants).
- **As an alternative to tissue culture:** As tissue culture is time consuming and technically demanding, EM is increasingly used as an alternative in various conditions such as.
  - Vesicular rashes: Herpes simplex virus and Varicella-zoster virus detection from vesicular fluid.
  - Meningitis: Detection of enteroviruses and mumps virus from CSF (cerebrospinal fluid).
- **Virus detection from tissue culture:** EM can also be used for detection of viral growth in tissue cultures.
- **Drawbacks:** EM is highly expensive, has low sensitivity with a detection threshold of 10^7 virions/mL. The specificity is also low.

Immuno-electron Microscopy

The sensitivity and specificity of EM can be improved by adding specific antiviral antibody to the specimen to aggregate the virus particles which can be centrifuged. The sediment is negatively stained and viewed under EM.

Fluorescent Microscopy

Direct immunofluorescence (Direct-IF) technique is employed to detect viral particles in the clinical samples.

- **Procedure:** Specimen is mounted on slide, stained with specific antiviral antibody tagged with fluorescent dye and viewed under fluorescent microscope.
- **Clinical applications:**
  - Diagnosis of rabies virus antigen in skin biopsies, corneal smear of infected patients.
  - Syndromic approach: Rapid diagnosis of respiratory infections caused by influenza virus, rhinoviruses, respiratory syncytial virus, adenoviruses and herpesviruses can be carried out by adding specific antibodies to each of these viruses.
  - Detection of adenovirus from conjunctival smears.

Light Microscopy

- **Inclusion bodies:** Histopathological staining of tissue sections may be useful for detection of inclusion bodies which helps in the diagnosis of certain viral infections. e.g. Negri bodies detection in brain biopsies of patients or animals died of rabies (Table 41.4).
- **Immunoperoxidase staining:** Tissue sections or cells coated with viral antigens are stained using antibodies tagged with horse radish peroxidise following which hydrogen peroxide and a coloring agent (benzidine derivative) are added. The color complex formed can be viewed under light microscope.

DETECTION OF VIRAL ANTIGENS

Various formats are available for detection of viral antigens in serum and other samples such as enzyme-linked immunosorbent assay (ELISA), immunochromatographic test (ICT), flow through assays, etc. Some important antigen detection tests include:

- HBsAg and HBeAg antigen detection for hepatitis B virus infection from serum.
- NS1 antigen detection for dengue virus infection from serum.
- p24 antigen detection for HIV infected patients from serum.
- Rotavirus antigen detection from diarrheic stool.
- CMV specific pp65 antigen detection (serum).

DETECTION OF VIRAL ANTIBODIES

Antibody detection from serum is one of the most commonly used method in diagnostic virology. Various techniques available are described below:

Conventional Diagnostic Techniques

These are less commonly used now a day. Examples include:

- Heterophile agglutination test (e.g. Paul-Bunnell test for Epstein-Barr virus).
- Hemagglutination inhibition (HAI) test for influenza virus and arbovirus infection.
- Neutralization test (for poliovirus and arbovirus infections).
- Complement fixation test or CFT (for poliovirus, arbovirus and rabies virus infections).

Newer Diagnostic Formats

Newer techniques such as ELISA, ICT, flow through assays are widely used for antibody detection against most of the viral infections for example:

- Anti-HBc, Anti-HBs and Anti-HBe antibodies for Hepatitis B infection.
- Anti-Hepatitis C antibodies.
- Antibodies against HIV-1 and HIV-2 antigens from serum.
- Anti-Dengue IgM/IgG antibodies from serum.

MOLECULAR METHODS

Advent of molecular techniques has eased the diagnosis of viral infections. They are more sensitive, specific and yield quicker results than culture.

Nucleic Acid Probe

It is an enzyme or radio-labelled nucleic acid sequence complementary to a part of nucleic acid sequence of the target virus.

- When added to the clinical specimen, it hybridizes to the corresponding part of viral nucleic acid.
- Depending on the type of label attached to the probe, the hybridized-labelled probe can be subsequently detected by colorimetric methods (dot blot hybridization) or gamma counting.
- Both DNA and RNA probes are commercially available.
- Nucleic acid probes have a low sensitivity compared to polymerase chain reaction (PCR) as it directly detects the viral genes in the specimen without amplification.

Polymerase Chain Reaction

PCR has revolutionized the diagnostic virology. It involves three basic steps—(1) viral DNA extraction from the specimen, (2) amplification of specific region of viral DNA to 10^7 folds, (3) detection of amplified products by gel electrophoresis.

Reverse Transcriptase PCR (RT-PCR)

RT-PCR is used for the detection of RNA viruses. After RNA extraction, the viral RNA is reverse transcribed to DNA, which is then subjected to amplification similar to that followed in PCR.

Both PCR and RT-PCR cannot quantify the viral nucleic acid load in the specimen.

Real Time PCR

It has the advantage of quantifying viral nucleic acid in the samples, hence used to monitor the treatment response, e.g., monitoring the response to antiretroviral therapy. More so, it takes much less time than PCR as the amplification is visualized on real time basis.

ISOLATION OF VIRUS

Viruses cannot be grown on artificial culture media. They are cultivated by animal inoculation, embryonated egg inoculation or tissue cultures.

- Being labor intensive, technically demanding and time consuming, virus isolation is not routinely used in diagnostic virology.
- The specimen should be collected properly and immediately transported to the laboratory. Refrigeration is essential during transportation as most viruses are heat labile. Type of specimen collected depends on the virus suspected.

Animal Inoculation

Because of the ethical issues related to use of animals, animal inoculation is largely restricted only for research use.

- **Research use:** To study viral pathogenesis or viral oncogenesis or for viral vaccine trials.
- **Diagnostic use:** Primary isolation of certain viruses which are difficult to cultivate otherwise; such as arboviruses and coxsackieviruses.
- **Procedure:** Infant (suckling) mice are used for the isolation of viruses. Specimens are inoculated by intracerebral or intraperitoneal routes. Mice are observed for signs of disease or death. Later on, they are sacrificed and the tissue sections are subjected to histological examination.
- Following intracerebral inoculation into suckling mice:
  - Coxsackie-A virus produces flaccid paralysis
  - Coxsackie-B virus produces spastic paralysis

Egg Inoculation

Embryonated hen's eggs are used for cultivation of viruses. Eggs were first used for viral cultivation by Good pasture in 1931 and the method was further developed later by Burnett.

Specimens can be inoculated by four different routes (Fig. 41.7) into embryonated 7 to 12 days old hen's eggs and then incubated for 2–9 days.

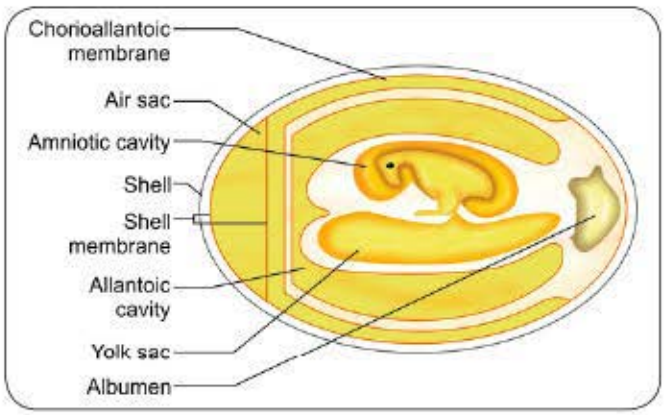

Fig. 41.7: Schematic diagram of embryonated egg

Yolk Sac Inoculation

It is preferred for arboviruses (e.g. Japanese B encephalitis virus, Saint Louis encephalitis virus, and West Nile virus) and some bacteria such as *Rickettsia*, *Chlamydia* and *Haemophilus ducreyi*. Growth of the encephalitis viruses may result in death of the embryo.

Amniotic Sac

It is mainly used for the primary isolation of the influenza virus and viral growth is measured by detection of hemagglutinin antigens in amniotic fluid.

Allantoic Sac

It is a larger cavity, hence is used for better yield of viral vaccines.

- **Example of egg derived vaccines** are influenza vaccine, yellow fever (17D) vaccine and Rabies (Flury strain) vaccine.
- **Duck eggs** are bigger than hen's eggs hence produce better yield of rabies virus for preparation of inactivated non-neural vaccine.

Chorioallantoic Membrane

It is preferred for poxviruses and other viruses such as HSV. Viruses produce visible lesions called as **pocks** on chorioallantoic membrane (CAM).

- **Pock counting:** Each pock is derived from a single virion. So, the number pocks would represent the number of viruses present in the inoculum.
- Pocks produced by different viruses have different morphology. For example:
  - Vaccinia pocks are more hemorrhagic and necrotic than pocks of variola virus.
  - Pocks of HSV-2 are larger than HSV-1.
- **Ceiling temperature:** It is the maximum temperature above which the pock formation is inhibited. Viruses vary in their ceiling temperature, e.g. variola (37°C) and vaccinia (41°C).

Tissue Cultures

Steinhardt was the first to use tissue culture in virology (1913) who maintained the vaccinia virus in fragments of rabbit cornea. Enders, Weller, and Robins (1949) were able to culture poliovirus in tissue cultures of non-neural origin and that was the turning point following which tissue culture was widely used in diagnostic virology.

Tissue culture can be of three types:

1. **Organ culture:** It was previously used for certain fastidious viruses that have affinity to specific organs; for e.g., tracheal ring culture for isolation of corona virus.
2. **Explant culture:** Fragments of minced tissue can be grown as 'explants', e.g. Adenoid explants used for adenoviruses. This method is obsolete now.
3. **Cell line culture:** This is the only isolation method which is in use now. The preparation of cell lines and the types of cell lines have been described below.

Preparation of the Cell Lines

Tissues are completely digested by treatment with proteolytic enzymes (trypsin or collagenase) followed by mechanical shaking is done so that the components are completely dissociated into individual cells.

- **Viral growth medium:** The cells are then washed, counted, and suspended in viral growth medium which contains balanced salt solution added with essential amino acids and vitamins, salts and glucose supplemented by 5–10% of fetal calf serum and antibiotics. Medium is buffered with bicarbonate to maintain a pH of 7.2–7.4 and phenol red is added as pH indicator.
- **Tissue culture flasks:** The viral growth medium containing cells is dispensed in tissue culture flasks. (Fig. 41.8).
- **Monolayer sheet formation:** On incubation, the cells adhere to the glass surfaces of the flask and then they divide to form a confluent monolayer sheet of cells within a week covering the floor of tissue culture flask.
- **Incubation:** Tissue culture flasks are incubated horizontally in presence of CO_2, either as a stationery culture or as a roller drum culture. Rolling of the culture bottle in *roller drums* provides better aeration which is useful for isolation of fastidious viruses (e.g. rotavirus).

Types of Cell Lines

The cell line cultures can be classified into three types based on their origin, chromosomal characters, and maximum number of cell divisions that they can undergo.

1. **Primary cell lines:** They are derived from normal cells freshly taken from the organs and cultured.

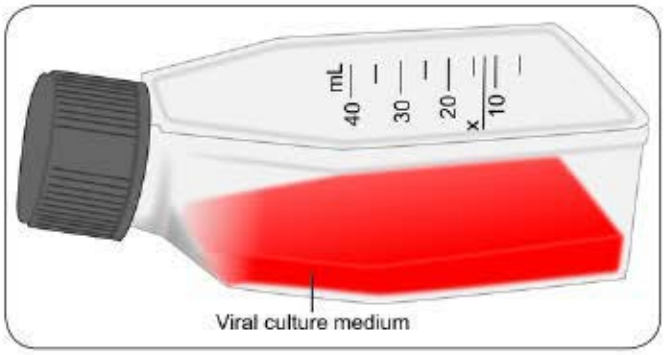

Fig. 41.8: Tissue culture flask

- They are capable of very limited growth in culture, maximum up to 5–10 divisions.
- They maintain a diploid karyosome.
- Useful for both primary isolation as well as growth of the viruses for vaccine production.
- Common examples include:
  - Monkey kidney cell line- useful for isolation of myxoviruses, enteroviruses and adenoviruses
  - Human amnion cell line
  - Chick embryo cell line

2. **Secondary or diploid cell lines:** They can divide maximum up to 10–50 divisions before they undergo senescence (death). They are also derived from the normal host cells and they maintain the diploid karyosome.
   Common examples: Diploid cell lines are derived from human fibroblasts and are useful for isolation of some fastidious viruses as well as for viral vaccine preparation.
   - Human fibroblast cell line: It is excellent for the recovery of CMV (Fig. 41.9).
   - MRC-5 and WI-38 (human embryonic lung cell strain):
     - Used for preparation of various viral vaccine, e.g., vaccine for rabies, chickenpox, hepatitis-A and MMR vaccines
     - They also support the growth of spectrum of viruses (e.g. HSV, VZV, CMV, adenoviruses, and picornaviruses)
3. **Continuous cell lines** (see the box below)

Fig. 41.9: Human lung fibroblast cell line (Normal)
Source: American Type Culture Collection (ATCC),USA (*with permission*)

Continuous Cell Lines

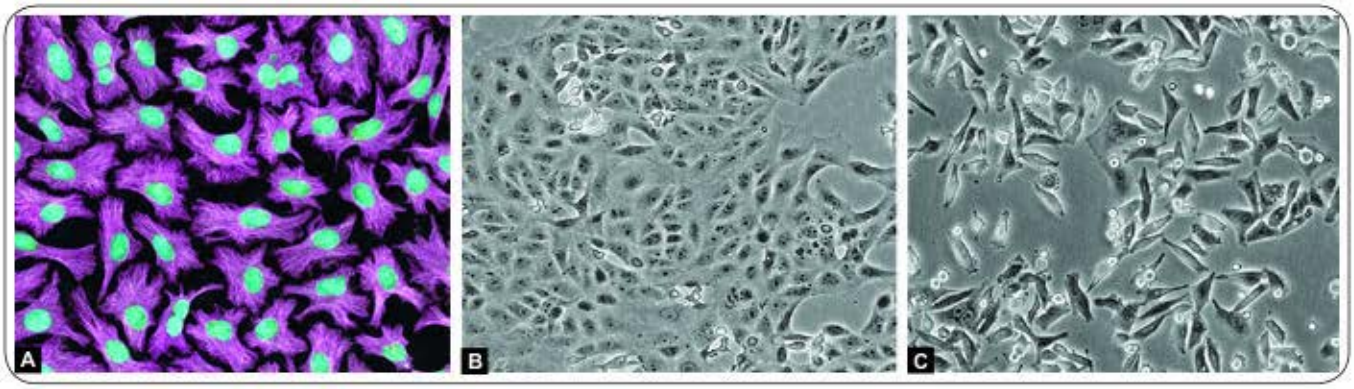
They are derived from cancerous cell lines, hence are immortal (capable of indefinite growth).They also possess altered haploid chromosome.
They are easy to maintain in the laboratories by serial sub culturing for indefinite divisions. This is the reason why continuous cell lines are the most widely cell lines.
***Common examples include* (Fig. 41.10)**
- HeLa cell line (Human carcinoma of cervix cell line).
- HEp-2 cell line (Human epithelioma of larynx cell line)- widely used for RSV, adenovairuses and HSV.
- KB cell line (Human carcinoma of nasopharynx cell line).
- McCoy cell line (Human synovial carcinoma cell line)- useful for isolation of viruses as well as *Chlamydia*.
- Vero cell line (Vervet monkey kidney cell line)-used for rabies vaccine production.
- BHK cell line (Baby hamster kidney cell line).

DETECTION OF VIRAL GROWTH IN THE CELL CULTURES

Following methods are used to detect the growth of the virus in cell cultures.

Cytopathic Effect (CPE)

It is defined as the morphological change produced by the virus in the cell line detected by light microscope.



Figs 41.10A to C: Continuous cell lines (normal, uninfected). **A.** HeLa cell line; **B.** Vero cell line; **C.** HEp-2 cell line
Source: American Type Culture Collection (ATCC), USA (*with permission*)

TABLE 41.6: Viral cytopathic effects (CPE)

Types of Cytopathic effect (CPE)	Virus
Rapid crenation and degeneration of the entire cell sheet	Enteroviruses
Syncytium or multinucleated giant cell formation	Measles, RSV, HSV
Diffuse roundening and ballooning of the cell line	HSV
Cytoplasmic vacuolations	SV 40 (Simian vacuolating virus-40)
Large granular clumps resembling bunches of grapes	Adenovirus

Abbreviations: RSV, respiratory syncytial virus; HSV, herpes simplex virus.

Cytopathic viruses: Not all, but few viruses can produce CPE and those are called as cytopathic viruses. The type of CPE is unique for each virus and that helps for their presumptive identification (Table 41.6)

Viral Interference

The growth of a non-CPE virus in cell culture can be detected by the subsequent challenge of the cell line with a known CPE virus.

- The growth of the first virus would inhibit infection by the second virus by a mechanism known as viral interference.
- For example, rubella is a non-CPE virus but prevents the replication of enteroviruses which are known to produce CPE.

Hemadsorption

Hemagglutinating viruses (e.g. influenza virus) when grown in cell lines, they produce hemagglutinin antigens which are coated on the surface of the cell lines and can be detected by adding guinea pig erythrocytes to the cultures. The process of adsorption of erythrocytes to the surfaces of infected cell lines cells is known as hemadsorption.

Directimmunofluorescence Assay

Virus infected cells are mounted on a slide and stained with specific antibodies tagged with fluorescent dye and viewed under fluorescent microscope for the presence of viral antigens on the surface of infected cells.

Immunoperoxidase Staining

Cells coated with viral antigens are stained by immuno-peroxidase tagged specific antibodies and viewed under light microscope.

Electron Microscopy

The viruses can also be demonstrated in infected cell lines by EM.

Viral Genes Detection

By using PCR or nucleic acid probes.

VIRAL ASSAYS

Quantitation of viruses can be done by both physical and biological methods.

Physical Methods

All these methods estimate the total virus count (or viral antigen or gene count) and cannot distinguish between infectious and non-infectious virus particles.

- **Real time PCR:** It can determine the number of viral genome copies in a sample.
- **Antigen detection assay** such as radioimmunoassays (RIA) and ELISA can be standardized to quantitate the amount of virus in a sample. However, these tests may detect free viral proteins that are not assembled into particles.
- **Hemagglutination assay:** It is an easy and rapid method of quantitating hemagglutinating viruses (e.g. influenza virus). The viral hemagglutinin antigens can agglutinate to the receptors on RBCs.
- **Electron microscopy:** Virus particles can be counted directly in the electron microscope by comparison with a standard suspension of latex particles of similar size.

Biological Methods

Biological methods detect the infectious virions only. Both qualitative (end point biological assays) or quantitative (plaque assay and pock assay) methods are available.

End Point Biological Assays

These assays depend on the measurement of animal death/lesion, or CPE produced in tissue culture when serial dilutions of the viral suspension are inoculated into animals or cells. The titer is expressed as the **50 percent infectious dose (ID_{50})**, which is the highest dilution of virus that produces the effect in 50% of the cells or animals inoculated.

Plaque Assay

It is the most widely used assay for quantifying infectious viruses.

- Monolayer of cell line is inoculated with suitable dilutions of the virus.
- After allowing time for adsorption of virus, the cell line is covered with an agar layer so the viruses would spread only to the immediate surrounding cells, but the spreading of the virus throughout the culture will be prevented.
- Multiple cycles of replication and cell killing produce a small area of infection called *plaque*.

- **Plaque counting**-As single plaque arises from a single infectious virus particle, hence the number of plaques counted would represent the quantitative infectivity titer of the virus suspension.

Pock Assay

Certain viruses such as variola, vaccinia and herpes form pocks on chorioallantoic membrane (CAM) of embryonated eggs. Number of pocks on CAM represents the approximate number of infective viruses present in the dilution inoculated.

TREATMENT OF VIRAL DISEASES

Unlike most bacteria, viruses are obligate intracellular and they use host machinery and enzymes for replication. Viral chemotherapy therefore was considered impracticable, as it was believed that it would inhibit cellular metabolism. Nevertheless, intense research made it possible to develop various antiviral drugs that can inhibit various steps of viral replication by targeting viral machineries without affecting host enzymes and without being toxic to host cells. However, the antiviral drugs are limited, not available against most of the viral diseases. Drugs currently approved for various viral diseases are listed in Table 41.7.

IMMUNOPROPHYLAXIS FOR VIRAL DISEASES

Viral Vaccines (Active Immunization)

Since viral antigens are potent immunogens, viral vaccines confer prolonged and effective immunity. Vaccines for viral infections may be available either in live, killed or in subunit forms. For certain viruses, both live and killed vaccines are available. (Table 41.8)

Killed Viral Vaccines

- **Preparation:** They are prepared by inactivating viruses with heat, phenol, formalin or beta propiolactone. Ultraviolet irradiation is not recommended because of the risk of multiplicity reactivation. For example, Rabies vaccine.
- **Advantages:** They are more stable and are considered safe when given in immunodeficiency or in pregnancy.
- **Disadvantages:** Killed vaccines are associated with more adverse side effects due to reactogenicity, which can be reduced to some extent by purification of viruses.

Subunit Vaccines

In subunit vaccines, only a particular antigen of the virus is incorporated.

TABLE 41.7: Commonly used antiviral drugs, their mechanism of action and spectrum of action

Antiviral drugs	Mechanism of action	Active against
Anti-herpesvirus drugs		
Acyclovir, valacyclovir, penciclovir	Inhibit Viral DNA polymerase	HSV1>HSV2>VZV and EBV
Famciclovir	Inhibit Viral DNA polymerase	HSV, VZV and HBV
Ganciclovir	Inhibit Viral DNA polymerase	CMV and EBV
Cidofovir	Inhibit Viral DNA polymerase	HSV and CMV
Foscarnet	Inhibit Viral DNA polymerase	HSV and CMV (including resistant strains)
Fomivirsen	Inhibit mRNA of CMV	CMV (including resistant strains)
Anti-influenza virus drugs		
Oseltamivir, zanamivir	Neuraminidase Inhibitor	H1N1 flu, Avian flu, Seasonal flu
Amantadine, rimantadine	Matrix protein inhibitor	Seasonal flu
Anti-hepatitis drugs		
Lamivudine	NRTI	Primarily for Hepatitis B
Adefovir, tenofovir	NtRTI	
Ribavirin	Inhibit viral RNA	Primarily for Hepatitis C
Interferon alpha		
Anti-retroviral therapy (ART)- Refer Chapter **48** Table 48.4		

Abbreviations: HSV, herpes simplex virus; VZV, varicella-zoster virus; CMV, cytomegalovirus; EBV, Epstein-Barr virus; NtRTI, nucleotide reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitors.

TABLE 41.8: Vaccines for viral infections

	Examples	Derived from
Inactivated vaccine		
Rabies Neural Vaccine	Semple vaccine	Sheep brain derived, inactivated with phenol
	BPL vaccine	Sheep brain derived, beta propiolactone inactivated
	Infant mouse brain vaccine	Neural tissue of newborn mice
Rabies Non-neural Vaccine	PCEC (purified chick-embryo cell) vaccine	Chicken fibroblast cell line
	HDC (human diploid cell) vaccine	Human fetal lung fibroblast cell line (WI-38 and MRC-5)
	Purified Vero cell (PVC) vaccine	Vero cell line
Kyasanur Forest Disease (KFD)	Killed KFD Vaccine	Formalin-inactivated chick embryo vaccine
Subunit vaccine		
Hepatitis B	HBsAg (Hepatitis B surface antigen)	Yeast (recombinant DNA technology)
Papilloma	L1 protein	Yeast (recombinant DNA technology)
Both live and inactivated vaccines		
Poliovirus	Live Oral Polio Vaccine (OPV)	Poliovirus types 1,2,3
	Killed Injectable Polio Vaccine (IPV)	Poliovirus types 1,2,3
Japanese B encephalitis	Nakayama strain (killed)	Formalin inactivated mouse brain derived
	Beijing strain (killed)	Formalin inactivated mouse brain derived
	SA 14-14-2 strain (live)	Primary hamster kidney cell line
Influenza	Killed vaccine	Embryonated chicken egg
	Live attenuated (intranasal)	Embryonated chicken egg
Yellow fever	17D live attenuated	Embryonated chicken egg
	Dakar strain(killed)	Mouse brain derived
Hepatitis A	Inactivated	Human fetal lung fibroblast cell line (WI-38 and MRC-5)
	Live attenuated	Human diploid cell line (H2 and L-A-1)
Live attenuated vaccine		
Mumps	Jeryl-Lynn strain	Embryonated chicken eggs and chicken embryo fibroblast cell line
Measles	Edmonston-Zagreb Strain	Chicken embryo fibroblast cell line
Rubella	RA 27/3 Strain	Human fetal lung fibroblast cell line (WI-38 and MRC-5)
Chickenpox	Oka strain of varicella-zoster	Human fetal lung fibroblast cell line (WI-38 and MRC-5)
Smallpox	Live vaccinia virus	Calf lymph
Rotavirus	Live attenuated	Vero cell line
Adenovirus	Live	Human fetal lung fibroblast cell line (WI-38 and MRC-5)

- **Preparation:** Subunit vaccines are prepared by DNA recombinant technology. The gene coding for the desired antigen is integrated into bacteria or yeast chromosome. Replication of the bacteria or yeast yields a large quantity of desired antigens, e.g. Hepatitis B vaccine.
- Unlike killed vaccines, there is no local side effects associated with subunit vaccines.

Live Vaccines

- **Preparation:** Most of the live vaccines are prepared by attenuation by serial passages. (Exception is smallpox vaccine where the naturally occurring vaccinia viruses were used for vaccination).
- **Advantage:** Live vaccines provide a stronger and long lasting immunity, mimicking immunity produced after natural infection. They are administered as a single dose (except OPV).
- **Disadvantages:** Live vaccines are risky in immunodeficiency or in pregnancy. They are less stable than killed vaccines.

Passive Immunization (Immunoglobulin)

Passive immunization is indicated when individual is immunodeficient or when an early effect is needed (i.e. for post-exposure prophylaxis). However, as there is no memory cells involved, passive immunisation have no role in prevention of subsequent infections.

- Previously used horse derived immunoglobulins were less effective with more side effects due to local hypersensitivity reactions; hence they are now replaced by human immunoglobulins.

- Currently, human immunoglobulins are available for the following viral infections:
  - Mumps
  - Measles
  - Hepatitis B
  - Rabies
  - Varicella-zoster

Combined Immunization

Simultaneous administration of vaccine and immunoglobulin in post exposure prophylaxis is extremely useful. It is recommended for:

- Hepatitis B (neonates born to HBsAg positive mothers or for unvaccinated people following exposure).
- Rabies (for exposures to severe class III bites).

EXPECTED QUESTIONS

I. Essay:

1. Discuss in detail laboratory diagnosis of viral infections.

II. Write short notes on:

1. Replication of viruses
2. Methods of detecting viral growth in cell cultures
3. Interferons
4. Inclusion bodies
5. Viral vaccines

III. Multiple Choice Questions (MCQs):

1. Which of the following viruses is/are enveloped?
a. Poliovirus
b. Adenovirus
c. Herpesvirus
d. Parvovirus B19

2. All of the following are RNA viruses except:
a. Human adenoviruses
b. Enterovirus
c. Coxsackievirus
d. Hepatitis A virus

3. All of the following viruses are transmitted by respiratory route except:
a. Influenza virus
b. Rotavirus
c. Respiratory syncytial virus
d. Rhinovirus

4. All of the following are continuous cell lines except?
a. HeLa cell line
b. Chick embryo cell line
c. HEp-2 cell line
d. KB cell line

5. Suckling mice are used for isolation of:
a. Coxsackievirus
b. HIV
c. Hepatitis B virus
d. Poliovirus

6. All of the following are intracytoplasmic inclusion bodies except:
a. Negri bodies
b. Molluscum bodies
c. Cowdry type A inclusions
d. Guarnieri bodies

7. Which of the following vaccine is a killed vaccine?
a. Mumps vaccine
b. Measles vaccine
c. Rubella vaccine
d. Semple vaccine

Answers

1. c **2.** a **3.** b **4.** b **5.** a **6.** c **7.** d

CHAPTER 42

Herpesviruses

Chapter Preview

- General properties
- Herpes simplex virus
- Varicella-zoster virus
- Cytomegalovirus
- Epstein-Barr virus
- Less common herpesviruses
  - Human herpesvirus 6
  - Human herpesvirus 7
  - Human herpesvirus 8
  - Herpes simian B virus

GENERAL PROPERTIES

Herpesviridae comprises of a group of viruses that possess a unique property of establishing latent or persistent infections in their hosts and later on undergoing periodic reactivation.

MORPHOLOGY

Herpesviruses are large (150–200 nm size), spherical in shape with icosahedral symmetry.

- **Nucleocapsid:** They possess a linear double-stranded DNA comprising of 125–240 kbp nucleotides surrounded by a capsid composed of 162 capsomeres (Fig. 42.1).

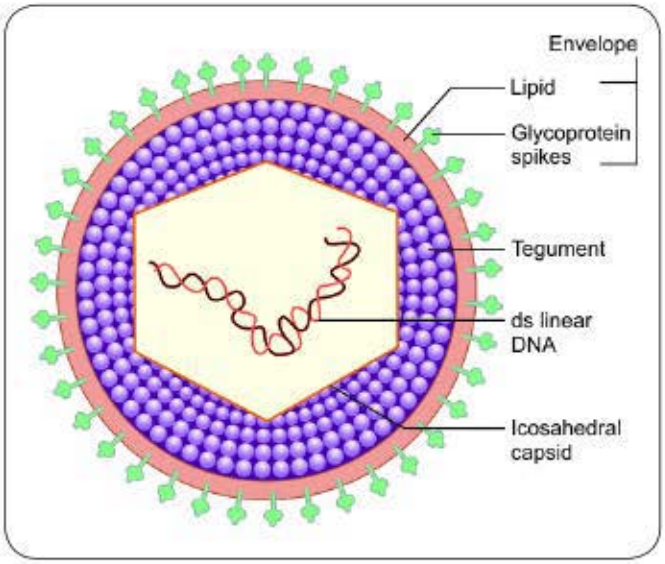


Fig. 42.1: Herpes simplex virus (schematic diagram)

- **Envelope:** The nucleocapsid is surrounded by an envelope which is lipoprotein in nature.
  - Lipid part: It is derived from the nuclear membrane of the infected host cell.
  - Protein part: Virus-coded glycoprotein spikes, about 8 nm long are inserted into the lipid part. They bind to the specific host cell receptors that help in viral entry.
- **Tegument:** Between the capsid and envelope, there is an amorphous, sometimes asymmetric structure present called tegument.
- **Unique feature of herpesvirus DNA:** The genome contains several reiterated (or repeated) genes, which undergo sequence arrangement between the members.
- **There is no DNA homology** between the members except:
  - Herpes simplex virus types 1 and 2 (exhibit 50% genomic sequence homology).
  - Human herpesviruses 6 and 7 (exhibit 30–50% sequence homology).
- **Replication** of herpesviruses takes place in the host cell nucleus and is similar to replication of any other dsDNA virus as described in Chapter 41. The only difference is that the linear dsDNA of herpesviruses becomes circular inside the host cell and then replicates by **rolling circle** mechanism.

CLASSIFICATION

Family Herpesviridae comprises of three subfamilies (α, β and γ)—classified based on the site of latency, duration of growth cycle and type of cytopathology they produce (Table 42.1).

TABLE 42.1: Classification of human herpesviruses

Subfamily ("Herpesvirinae")	Duration of replication and cytopathology	Site of latency	Genus	Species	
				Official name	Common name
Alpha	Short (12–18 hours) Cytolytic	Neurons	*Simplex virus*	Human herpesvirus 1	Herpes simplex virus type 1
				Human herpesvirus 2	Herpes simplex virus type 2
			Varicellovirus	Human herpesvirus 3	Varicella-zoster virus
Beta	Long (>24 hours) Cytomegalic	Glands, kidneys	*Cytomegalovirus*	Human herpesvirus 5	Cytomegalovirus
	Long (>24 hours) Lymphoproliferative	Lymphoid tissues (T cells)	*Roseolovirus*	Human herpesvirus 6	Human herpesvirus 6
				Human herpesvirus 7	Human herpesvirus 7
Gamma	Variable, lymphoproliferative	Lymphoid tissues (B Cells)	*Lymphocryptovirus*	Human herpesvirus 4	Epstein-Barr virus
			Rhabdinovirus	Human herpesvirus 8	Kaposi's sarcoma-associated herpesvirus

- Each subfamily in turn has one or more genera and each genus consists of a few species.
- For general use, the common names are still popular, which are also followed in this textbook.
- There are about 100 herpesviruses infecting different animals, out of which only eight are human herpesviruses which infect exclusively man.
- Rarely, some herpesviruses infecting animals (e.g., herpes simian B virus of monkey) can infect man.

HERPES SIMPLEX VIRUS

Herpes simplex viruses belong to α-subfamily of Herpesviridae.

- They are extremely widespread and exhibit a broad host range; can infect many types of cells and different animals. However, the human herpesviruses infect exclusively man.
- They replicate fast (12–18 hours cycle), spread fast and are cytolytic.
- They can cause a spectrum of diseases, involving skin, mucosa and various organs.
- They undergo **latency in nerve cells**; reactivate later causing recurrent lesions.

Herpes simplex viruses (HSV) are of two distinct types: HSV-1 and HSV-2. They differ from each other in many aspects (Table 42.2).

TABLE 42.2: Differences between HSV-1 and HSV-2

Properties	Herpes simplex virus 1	Herpes simplex virus 2
Common modes of transmission	Direct contact with mucosa or abraded skin	Sexual mode or vertical mode
Latency in	Trigeminal ganglia	Sacral ganglia
Age affected	Young children	Young adults
Antibody distribution	Present in 70–90% of people (adult)	Present in 20% of people (adult)
Common manifestations	▪ Oral-facial mucosal lesions ▪ Encephalitis and meningitis ▪ Ocular lesions ▪ Skin lesions—above the waist	▪ Genital lesions ▪ Skin lesions-below the waist ▪ Neonatal Herpes
Egg (CAM*)	Forms smaller pocks	Forms larger pocks
Chick embryo fibroblast	Does not grow well	Replicates well
Neurovirulence	Less	More
Drug resistance	Less	More
Antigenic homology	HSV-1 and 2 show >80% antigenic homology	
DNA homology	HSV-1 and 2 show >50% homology in the genomic sequence	

*CAM—Chorioallantoic membrane

Pathogenesis

Primary Infection

- **Transmission** occurs through abraded skin or mucosa from any site, but more commonly by:
  - **HSV-1:** Oropharyngeal contact with infected saliva or direct skin contact.
  - **HSV-2:** Sexual contact or rarely vertical mode (from mother to fetus).

- **Site of infection:** HSV replicates at the local site of infection and produces lesions anywhere, but more commonly in:
  - HSV-1 lesions are confined to areas above the waist (most common site—around mouth).
  - HSV-2 produces lesions below the waist (most common site—genital area).
- **Spread via nerve:** Virus then invades the local nerve endings and is transported by retrograde axonal flow to the dorsal root ganglia, where it replicates further, and then undergoes latency.
- Primary HSV infections are usually mild; in fact, most are asymptomatic.
- However in immunocompromized hosts, viremia occurs that leads to widespread organ involvement and systemic manifestations.

Latent Infection

- HSV has a tendency to undergo latency in neurons:
  - HSV-1—undergoes latency in trigeminal ganglia.
  - HSV-2—undergoes latency in sacral ganglia.
- **Non replicating state:** HSV does not replicate in latent stage except for a small RNA, called **micro-RNA** (encoded by a latency-associated viral gene) which maintains the latent infection and prevents cell death.
- The virus cannot be isolated during latency.

Recurrent Infections

Reactivation of the latent virus can occur following various provocative stimuli, such as fever, axonal injury, physical or emotional stress, and exposure to ultraviolet light.

- **Via the axonal spread**, virus goes back to the peripheral site and further replicates in skin or mucosa producing secondary lesions.
- **Recurrent infections** are less extensive and less severe because of presence of pre-existing host immunity that limits the local viral replication.
- Many recurrences are asymptomatic; but viruses are shed in the secretions.

Clinical Manifestations

Both HSV-1 and 2 have been isolated from nearly all mucocutaneous sites and viscera; however, in general, oral-facial infections are common with HSV-1, whereas HSV-2 frequently causes genital infections and intrauterine infections. The incubation period ranges from 1 to 26 days (median, 6–8 days).

Oral-facial Mucosal Lesions

Oral-facial mucosal lesions are the most common manifestations of HSV.

- Most common affected site is buccal mucosa.

Figs 42.2A and B: A. Vesicular lesions on lips and tongue due to HSV-1 infection; **B.** Periocular vesicular lesions due to HSV-1 infection

Source: Public Health Image Library, A. ID# 12616 (Robert E. Sumpter), B. ID# 6492 (Dr. K.L. Hermann)/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Most frequent primary lesions are gingivostomatitis and pharyngitis.
- Most frequent recurrent lesion is herpes labialis (painful vesicles near lips) (Figs 42.2A and B).
- Other lesions produced are—ulcerative stomatitis and tonsillitis.
- Many cases are asymptomatic but can predispose to secondary bacterial infection.

Nervous System

- **Encephalitis:** HSV is the most common cause (10–20%) of acute sporadic viral encephalitis, most frequently involving temporal lobe. HSV-1 is more common (95%) than HSV-2.
  - Children get primary infection: HSV is acquired exogenously and invades CNS via the olfactory bulb.
  - Adults get recurrent infections due to reactivation of HSV in trigeminal nerve.
- **Meningitis:** HSV can cause recurrent lymphocytic meningitis called Mollaret's meningitis.
- **Other manifestations:**
  - Autonomous nervous system involvement (sacral region).
  - Transverse myelitis.
  - Guillain-Barré syndrome.
  - Peripheral nervous system involvement (e.g. Bell's palsy).

Cutaneous Lesions

HSV usually infects through abraded skin and causes various lesions.

- **Herpetic whitlow:** Lesions present on the fingers of dentists and hospital personnel.
- **Febrile blisters:** Fever due to any other cause can provocate HSV to cause recurrent blisters.
- **Herpes gladiatorum:** Mucocutaneous lesions present on the body of wrestlers.

- Skin lesions are often severe on underlying eczema or burns which permit extensive local viral replication and spread.
- **Eczema herpeticum:** Caused by HSV-1 in patients with chronic eczema. Similar lesions are also produced by vaccinia virus infection; both conditions together are designated as Kaposi's varicelliform eruptions.
- **Erythema multiforme:** HSV is the most common to be associated with this condition. Herpes antigens have been detected in the immune complexes found in serum or skin biopsies.

Ocular Lesions

HSV-1 is more common than HSV-2 to infect eyes.

- Severe conjunctivitis is the most common manifestation.
- Recurrent lesions develop into **dendritic ulcers** of cornea or vesicles on the eyelids.
- **Corneal blindness:** Involvement of corneal stroma may cause opacity and blindness. HSV-1 infections are second only to trauma as a cause of corneal blindness.

Genital Lesions

HSV-2 is more common than HSV-1 to cause primary as well as recurrent genital lesions.

- Genital lesions are described as bilateral, painful, multiple, tiny vesicular ulcers.
- This may be associated with fever and inguinal lymphadenopathy.

Visceral and Disseminated Herpes

- **Risk factors:** Immunocompromized patients, underlying malnutrition or AIDS, pregnant women and transplant recipients are at a higher risk of developing viremia and disseminated infection.
- **Common manifestations include:** Pneumonitis, tracheobronchitis and hepatitis.

Neonatal Herpes

HSV is one of the common causes of congenital infections, along with the other TORCH agents (Chapter 57).

- **Transmission:** Newborns acquire HSV infection most commonly during birth from the maternal genital tract. However, transmission can also occur *in utero* or after birth.
- **Risk** of developing neonatal herpes is maximum (10 times more) if the mother recently acquires the virus (primary infection) than those who present with recurrent infection.
- **HSV-2** is more common to cause neonatal herpes (75% of total cases) than HSV-1.
- **Clinical features:** Babies are almost always symptomatic and present in one of the three forms:
  - Local lesions involving skin, eye and mouth.
  - Encephalitis: It is associated with higher mortality and if survived, then babies are left with permanent neurological impairment.
  - Disseminated disease involving multiple organs, including the CNS-neonates are at highest risk of disseminated visceral infections.

Epidemiology

Herpes simplex viruses are worldwide in distribution. No animal reservoirs or vectors are involved with the human viruses. HSV-1 and 2 differ in their epidemiological pattern.

Epidemiological Pattern of HSV-1

- **Transmission:** HSV-1 infection is more common and is transmitted by contact with infected secretions (saliva).
- Primary infection occurs early in life and is either asymptomatic or remains confined to oropharyngeal disease.
- **Age:** Children are commonly affected.
- **Adults:** Antibodies develop in 70–90% of adults, but they fail to eliminate the virus from the body. Most adults become carriers throughout the life, occasionally get transient recurrent attacks.

Epidemiological Pattern of HSV-2

- HSV-2 is transmitted by sexual or vertical routes.
- Primary infection occurs in adult life. Antibodies develop only in 20% of people particularly among black women than men and whites.
- HSV-2 tends to recur more often than HSV-1, irrespective of the site of infection.

LABORATORY DIAGNOSIS — Herpes simplex virus

- Cytopathology (Tzanck preparation) by Wright's or Giemsa stain-detects inclusion bodies (Lipschultz body) and formation of multinucleated giant cells
- Virus isolation by:
  - Conventional cell lines—detects diffuse rounding and ballooning of cell lines
  - Shell vial culture—detects antigens in cell line by IF
- Viral antigen detection in specimen by direct IF
- HSV DNA detection by PCR
- Antibody detection by ELISA or other formats

Laboratory Diagnosis

The sensitivity of all the methods to diagnose HSV infection depends on the type of specimen, as well as the type of infection. The sensitivity is more for vesicular lesions and primary infection than for ulcerative lesions and recurrent infections.

Cytopathology

Scrapings obtained from the base of the lesion can be stained with Wright's or Giemsa (Tzanck preparation), or

Papanicolaou stain. Sensitivity of staining is low (<30% for mucosal swabs). It cannot differentiate between HSV-1, HSV-2, and varicella-zoster virus; as all of them produce similar but characteristic cytopathological changes such as:

- Production of Cowdry type A intranuclear inclusion bodies (Lipschultz body).
- Formation of multinucleated giant cells (Fig. 42.3A).
- Ballooning of infected cells, margination of chromatin.

Virus Isolation

It remains the most definitive tool for HSV diagnosis. Growth inside the cell lines can be detected in 2–4 days by:

- **Characteristic cytopathic effect:** Diffuse rounding and ballooning of the infected cells.
- Viral antigen detection by neutralization test or immunofluorescence staining with specific antiserum.
- Shell vial technique can be followed to decrease the detection time to <24 hours.

Viral Antigen Detection by Immunofluorescence

Viral antigen detection by direct IF is also a sensitive and specific assay. It can differentiateHSV-1 from HSV-2.

HSV DNA Detection by PCR

Polymerase chain reaction (PCR) is the most sensitive test for detecting HSV infections and can be used to differentiate between HSV-1 and HSV-2.

Antibody Detection

Antibodies appear in 4–7 days after the infection and peak in 2–4 weeks. IgM appears first and is replaced by IgG, which persists for life.

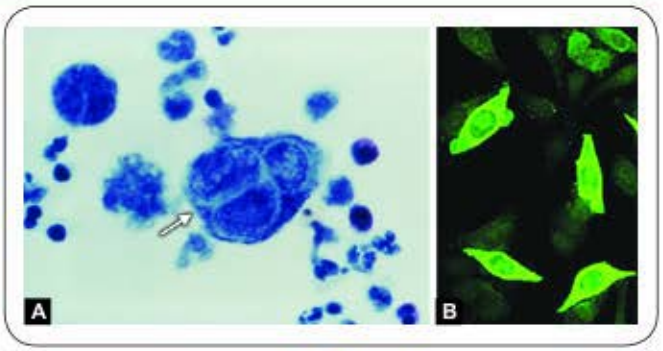
- Most available tests usually detect IgG or total antibodies, hence cannot differentiate between recent and past infections. Seroconversion or a rise in titer is more meaningful.
- Serologic assays based on the type-specific antigens can differentiate between HSV-1 and HSV-2.
- Both ELISA and indirect IF formats are available (Fig. 42.3B).

TREATMENT **Herpes simplex virus**

Several specific antiviral drugs are effective for HSV infections. Acyclovir is the drug of choice. It acts by inhibiting viral DNA polymerase.

- **For mucocutaneous infections:** Acyclovir and its congeners famciclovir and valacyclovir have been the mainstay of treatment.
- **Ocular infection:** Topical idoxuridine, trifluorothymidine, topical vidarabine, and cidofovir are used.
- **For HSV encephalitis and neonatal herpes,** IV acyclovir is the treatment of choice.

Acyclovir resistance has been reported among few HSV strains which have altered substrate specificity for phosphorylating acyclovir. Foscarnet is the drug of choice to treat such cases.



Figs 42.3A and B: A. Tzanck smear of a tissue scraping showing multinucleated giant cell (Tzanck cell) in the center (arrow showing); **B.** Indirect IF for HSV1/2 antibody detection

Source: A. Public Health Image Library, ID# 14428/Centers for Disease Control and Prevention (CDC), Atlanta; B. Euroimmun (*with permission*)

Prevention

General measures can be taken such as:

- Use of condom to prevent genital herpes.
- Neonatal herpes can be prevented by prior administration of acyclovir to mothers during third trimester of pregnancy or delivery by elective caesarean section.
- No vaccine is currently licensed. Several vaccine trials are going on, such as recombinant HSV-2 glycoprotein vaccine.

VARICELLA-ZOSTER VIRUS

Varicella-zoster virus (VZV) produces vesicular eruptions (rashes) on the skin and mucous membranes in the form of two clinical entities:

1. **Chickenpox:** It is characterized by generalized diffuse bilateral vesicular rashes which occur following primary infection, usually affecting children.
2. **Zoster or shingles:** It occurs following reactivation of latent VZV, present in the trigeminal ganglia that occurs mainly in adult life. Vesicular rashes are unilateral and segmental (confined to the skin innervated by a single sensory ganglion).

Chickenpox

Pathogenesis

- **Portal of entry:** VZV enters through the upper respiratory mucosa or the conjunctiva.
- **Spread:** It replicates in the regional lymph nodes → spills over and enters the blood stream (primary viremia) → spreads to the liver and spleen, and multiplies → again enters bloodstream (secondary viremia) → VZV present in the infected mononuclear cells are transported to:

Fig. 42.4: Vesicular rashes in chickenpox

Source: Public Health Image Library, ID# /5409/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Skin:** Virus replication in the epithelial cells leads to development of typical rashes. Swelling of epithelial cells, ballooning degeneration, and accumulation of tissue fluids result in the formation of vesicles.
- **Respiratory tract:** VZV is shed in the respiratory secretions of the infected individuals leading to the transmission of infection to other individuals.
- **Neurons:** VZV gains access to neurons of trigeminal ganglia and undergoes latency.

Clinical Manifestations

- Incubation period is about 10–21 days (2–3 weeks).
- Typical description of chickenpox rashes:
  - Rashes are vesicular (Fig. 42.4).
  - Centripetal in distribution-Usually start on the face and trunk, spread rapidly to involve flexor surfaces.
  - Bilateral and diffuse in distribution.
  - **Rashes appear in multiple crops:** Lesions in various stages of evolution, such as maculopapules, vesicles, and scabs can be found in one area at the same time.
  - Fever appears with each crop of rashes.
- Chickenpox is a disease of childhood.
- When occurs in adults, it is more severe with bullous and hemorrhagic rashes.

Complications

Complications are more common in adults and in immunocompromized individuals.

- **Most common infectious complication is:** Secondary bacterial infection of the skin.
- **Most common extracutaneous complication is:** CNS involvement (cerebellar ataxia, encephalitis and aseptic meningitis), usually occurs in children.
- **Most serious complication is:** Varicella pneumonia, which develops more commonly in adults (up to 20% of cases) than in children and is particularly severe in pregnant women.
- **Reye's syndrome** can occur secondary to VZV infection. It is characterized by fatty degeneration of liver following salicylate (aspirin) intake.
- **Other complications are:** Myocarditis, nephritis, corneal lesion and arthritis

Chickenpox in Pregnancy

Chickenpox in pregnancy can affect both mother and the fetus.

- **Mothers** are at high risk of developing varicella pneumonia
- **Fetal or congenital varicella syndrome:** VZV is highly teratogenic. Risk is maximum when mother acquires a primary infection during pregnancy.
  - **First half of pregnancy:** Fetus remains mostly asymptomatic.
  - **Second half of pregnancy:** Congenital malformation in fetus is more frequent, characterized by **cicatricial skin lesions, limb hypoplasia** and **microcephaly.**
- **Infection near delivery:**
  - If mother gets infection > 5 days before delivery—then baby is mostly asymptomatic due to protective maternal antibody.
  - If mother gets infection **5 days before to 2 days after** the delivery—maternal antibodies would not have produced in such a short time. This leads to dissemination of virus in the baby to cause **neonatal varicella** (a severe form of chickenpox with mortality rate exceeding 30%).

Epidemiology

Chickenpox is a highly contagious disease.

- **Period of infectivity:** Child is infectious from 2 days before the onset of rash to 5 days thereafter, until the vesicles are crusted.
- One attack gives lifelong immunity.
- **Reservoir:** Humans are the only known reservoir host.
- **Source of infection:** Patients are the only source, there are no carriers.
- Secondary attack rate is about 70–90%.

Zoster or Shingles

Zoster usually occurs due to reactivation of latent VZV in old age (> 60 years of age), in immunocompromized individuals or occasionally in healthy adults.

- It usually starts with severe pain in the area of skin or mucosa supplied by one or more groups of sensory nerves and ganglia.
- **Rashes:** They are unilateral and segmental, confined to the area of skin supplied by the affected nerves.
- **Most common nerve involved** is ophthalmic branch of trigeminal nerve. Head, neck and trunk are the most common affected sites.

Complications of Zoster

- **Post-herpetic neuralgia** (pain at the local site lasting for months): It is the most common complication in elderly patients.
- **Zoster ophthalmicus:** Unilateral painful crops of skin rashes surrounding the eye.
- **Ramsay Hunt syndrome** develops when geniculate ganglion of facial nerve is involved. It is characterized by tetrad of facial nerve palsy plus vesicle on tympanic membrane, external auditory meatus and the tongue.
- **Visceral disease**, especially pneumonia can occur which claims for the most common cause of death (<1%) in zoster patients.

Laboratory Diagnosis

- **Cytopathology:** Giemsa staining of the scrapings from the ulcer base (Tzanck smear) reveals cytopathological changes similar to that of HSV infection, such as formation of multinucleated giant cells.
- **Virus isolation:** Virus isolation in various cell lines can also produce HSV-like cytopathic effects such as diffuse rounding and ballooning of infected cells.
- **VZV-specific methods:**
  - Specific antigen detection by direct immunofluorescence staining.
  - PCR detecting VZV-specific genes.

TREATMENT **Varicella-zoster virus**

Acyclovir is the drug of choice. It can prevent the complications of chickenpox and can also halt the progression of zoster in adults, but cannot prevent post-herpetic neuralgia.

Vaccine

Live attenuated vaccine using **Oka strain** of VZV is available.

- It is given to children after 1 year of age; 2 doses, first dose is given at 12–15 months and second at 4–6 years.
- In seronegative adults; 2 doses given at 1-month gap.
- Transmission of the vaccine virus can occasionally cause mild rashes in the recipient.
- Protectivity: The vaccine is > 80% effective in preventing chickenpox in children but less so in adults (70%). However, it is 95% effective in preventing severe disease.

VZIG (Varicella-zoster Immunoglobulin)

- It is recommended for post exposure prophylaxis. It is given within 96 hours (preferably 72 hours) of exposure.
- It is also indicated for neonates born to mothers suffering from chickenpox if the onset of chickenpox in mother is between <5 days before delivery till 48 hours after delivery. VZIG is not indicated for the neonate if the mother has zoster.

CYTOMEGALOVIRUS

Cytomegalovirus (CMV) is the largest virus in Herpesviridae family. It is so named because it causes massive enlargement of infected host cells.

Properties of CMV are similar to any other herpesvirus described earlier with some minor differences.

- CMV belongs to β-subfamily.
- Its dsDNA is the largest among herpesviruses, which consists of 240 kbp nucleotides.
- **Host specificity:** Cytomegaloviruses are strictly species-specific. Human CMV does not infect animals. Similarly, a number of animal CMVs exist, which do not infect humans.
- **Cell-type specificity**
  - In vivo, CMV infects kidney and salivary glands; where it undergoes latency.
  - In vitro, CMV replicates only in human fibroblast cell line and produces a characteristic cytopathic effect (CPE) described as **Owl's eye** appearance (Fig. 42.5).
- **Cell-to-cell spread:** CMV is almost always closely associated with the cells and spread primarily cell-to-cell, so that very little virus may be cell-free.

Clinical Manifestations

CMV causes an array of clinical syndromes such as congenital and perinatal infections, CMV mononucleosis in adults and severe infection in immunocompromized and transplant recipients.

Congenital CMV Infection

CMV is probably the most common intrauterine infection associated with congenital defects.

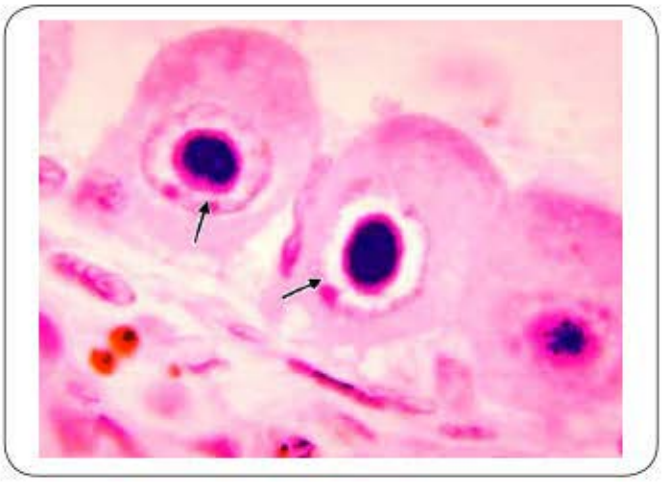


Fig. 42.5: Histopathology of kidney shows cytomegalic host cell containing characteristic Owl's eye inclusion (arrows showing)

Source: Public Health Image Library, ID# /1155 Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- About 1% of infants born are infected with CMV.
- Cytomegalic inclusion disease develops in about 5% of the infected fetus. The remaining are although asymptomatic at birth, 5–25% of them may develop significant psychomotor, hearing, ocular, or dental defects within 2 years.
- **Congenital defects include:**
  - Most common defects are petechiae, hepatosplenomegaly, and jaundice (60–80% of cases).
  - Less common defects include-microcephaly, cerebral calcifications, intrauterine growth retardation, and prematurity (30–50% of cases).
  - Occasional defects are inguinal hernias and chorioretinitis.
- **Risk is maximum** if the infection occurs in early pregnancy and if the mother is primarily infected during pregnancy (one third of the primarily infected mothers transmit the virus to fetus in contrast to 1% of reactivated mothers).
- Mortality rate is very high (20%).

Perinatal CMV Infection

- Transmission to the newborn occurs either during:
  - Delivery—through infected birth canal or
  - Postnatal—through infected breast milk/secretions from mother.
- Most of the infected infants remain asymptomatic, but shed virus in urine from 8–12 weeks of age, up to several years.
- Few infants, especially premature babies develop interstitial pneumonitis.

Immunocompetent Adults

In healthy adults, CMV produces an infection following blood transfusion called **mononucleosis-like syndrome**. This condition is similar to infectious mononucleosis caused by EBV (described later in this chapter) (Table 42.3):

TABLE 42.3: Comparison of infectious mononucleosis and mononucleosis-like syndrome

Features	Infectious mononucleosis	Mononucleosis-like syndrome
Agent	Epstein-Barr virus (EBV)	CMV (20–50%) HHV-6 *Toxoplasma* *Ehrlichia* HIV
Atypical lymphocytosis	Seen	Seen
Clinical symptoms	Fever, myalgia, Hepatosplenomegaly, Exudative pharyngitis, Cervical lymphadenopathy, Rashes following ampicillin therapy	Similar presentation, except that exudative pharyngitis, cervical lymphadenopathy are absent
Heterophile antibodies	Elevated (detected by a Paul Bunnell test)	Negative
Specific antibodies	Antibodies to specific EBV antigens are elevated	Antibodies to CMV or other agents may be elevated.

In the Immunocompromized Host

CMV produces markedly severe infection in immunosuppressed individuals; most of which are due to reactivation of their own latent viruses.

- **In AIDS patients** with CD4 T cell count <50/μL —CMV may cause chorioretinitis, gastroenteritis, dementia and other disseminated CMV infection.
- **Organ transplant recipients:** CMV is probably the most common viral infection that occurs in transplant recipients. Infection occurs usually between 1 and 4 months following transplantation and presents in various forms such as:
  - Bilateral interstitial pneumonia is the most common form, seen in 15–20% of bone marrow transplant recipients.
  - Febrile leukopenia is seen among solid organ transplant recipients.
  - Obliterative bronchiolitis in lung transplants.
  - Graft atherosclerosis in heart transplants.
  - Rejection of renal allografts.

Epidemiology

- **Transmission:** Close person-to-person contact is required for transmission (unlike HSV). Various modes of transmission include:
  - Oral and respiratory spread is the predominant mode.
  - Transplacental route (transmission from mother to fetus).
  - Blood transfusion: Risk of transmission is about 0.1–10% per blood unit transfused.
  - Organ transplantation.
  - Sexual contact (in young adults).
- **Reservoir:** Humans are the only known host for CMV.
- **Source:** Virus may be shed in urine, saliva, semen, breast milk, and cervical secretions, and is carried in circulating white blood cells.
- **Endemic:** CMV is endemic worldwide, present throughout the year without any seasonal variation.
- **Risk factors** such as low socioeconomic status and poor personal hygiene facilitate the infection.
- **Prevalence** is high in underdeveloped nations with 90% of people being seropositive in contrast to 40–70% seropositivity in developed nations.

LABORATORY DIAGNOSIS — Cytomegalovirus

- Cytopathology—detects inclusion bodies with owl's eye appearance
- Virus isolation:
  - Human fibroblasts cell line culture—detects CPE after 2–3 weeks
  - Shell vial culture—detects viral antigens in infected cell lines by IF (1-2days)
- Antibody detection—by ELISA and rapid test formats
- Antigen detection such as pp65 antigen
- Molecular methods—PCR and real-time PCR

Laboratory Diagnosis

Detection of Inclusion Bodies

In urine, CMV produces characteristic perinuclear cytoplasmic inclusions in addition to the usual intranuclear inclusions seen in other herpesviruses (Owl's eye appearance) (Fig. 42.5).

Virus Isolation

CMV can be isolated from throat washings and urine.

- Human fibroblasts are the most ideal cell lines, specific for CMV.
- **Cytopathic effect:** After 2–3 weeks of incubation, the following CPE may be observed in the infected cell line:
  - Typical CMV inclusions (as described above).
  - Multinucleated giant cells are seen.
  - Enlargement of infected host cells.
- **Shell vial technique** can be followed for early growth detection (1–2 days).
  - It involves centrifugation of cell culture (mixed with the specimen) to enhance the cell contact and viral replication followed by detection of early CMV antigen in the infected cells by direct fluorescence technique.
  - It is very useful in CMV mononucleosis where viral load is low and CPE takes several weeks to appear.

Antibody Detection

Various formats such as ELISA and rapid tests are available for detecting serum antibodies.

- IgM antibodies are indicative of active infection, but appear only after 4 weeks of primary infection.
- IgG antibodies persist for life and suggest either past infection or recurrent infection. Fourfold rise of IgG indicates recurrent infection.
- Antibodies are often undetectable in immunocompromized patients.
- Antibody detection cannot distinguish strain differences among the clinical isolates.

Antigen Detection

CMV-specific **pp65 antigen** can be detected in peripheral-blood leukocytes by using specific monoclonal antibody. It is highly specific and reliable method.

Molecular Methods

Molecular methods such as PCR can be used to detect specific CMV DNA in blood or body fluids such as CSF.

- PCR assays are rapid, highly sensitive, specific and have replaced the gold standard culture technique in most laboratories.
- Real time PCR can quantitate the viral load, hence it is the method of choice to monitor the treatment response.

TREATMENT — Cytomegalovirus

CMV does not respond to acyclovir. The following drugs are used for treatment of CMV infections.

- **Ganciclovir:** It is the drug of choice for cytomegalic inclusion disease or in neonates or for severe CMV infections such as retinitis or transplant infections.
  - It is given by intravenous route.
  - Mechanism of action: It is converted by viral phosphotransferase encoded by CMV UL97 gene to form ganciclovir triphosphate that inhibits CMV DNA polymerase.
- **Valganciclovir:** It is a pro-drug of ganciclovir that can be given orally.
- **Foscarnet:** It inhibits CMV DNA polymerase, without undergoing phosphorylation. Hence, it is effective against most ganciclovir-resistant isolates.
- **Cidofovir:** It is also given alternative to ganciclovir, but is nephrotoxic.
- **CMV immunoglobulin:** It is given along with ganciclovir for the treatment of CMV infections in bone marrow transplant recipients.

Prophylaxis

- Both ganciclovir and valganciclovir have been used successfully for prophylaxis and pre-emptive therapy in transplant recipients.
- CMV immunoglobulin has shown to be effective in preventing congenital infection when given to mother during pregnancy.

EPSTEIN-BARR VIRUS

Epstein-Barr Virus (EBV) is a member of γ sub-family of Herpesviridae that causes infectious mononucleosis and is also associated with several human tumors, including nasopharyngeal carcinoma, Burkitt's lymphoma, Hodgkin's disease, and B cell lymphoma.

Antigens of EBV

EBV antigens are divided into three classes:

- **Latent phase antigens:** They are synthesized during the period of latency, e.g.
  - EBV nuclear antigen (EBNA): It has six subtypes.
  - Latent membrane protein (LMP): It has two subtypes.
- **Early antigens:** They are non-structural proteins which help in viral replication.
- **Late antigens:** They are the structural proteins that form viral capsid and envelope.

Pathogenesis

Primary Infection

EBV is transmitted by oropharyngeal contact through infected salivary secretions.

- **EBV receptors:** EBV binds to specific receptors present on B cell (CD21 or CR2) which are also receptors for C3b component of complement. Such receptors are also present on pharyngeal epithelial cells.
- **Primary infection** occurs in the oropharynx. EBV replicates in epithelial cells or surface B lymphocytes of the pharynx and salivary glands.
- **Following entry** into the B cells, EBV directly enters into latent phase without completing the viral replication.
- Though, majority of the infected cells are eliminated, a small number of infected cells (one in 10^5–10^6 B cells) may persist for lifetime. Virus spreads from the oropharynx to other sites of the body and is capable of undergoing reactivation later.
- **Viral shedding** continues in oropharyngeal secretions at low levels for weeks to months and serves as source of infection.
- In children, most primary infections are subclinical, but young adults often develop a condition called as acute infectious mononucleosis.
  - Infected B cells become *immortalized* by the virus and synthesize large number of variety of immunoglobulins (polyclonal), many of those are autoantibodies (e.g. heterophile antibody to sheep RBC antigen)
  - In response to this, the bystander CD8 T lymphocytes are stimulated and appear atypical.

Mechanism of Oncogenesis of EBV

Persistent EBV infection can induce malignant transformation of infected B cells and epithelial cells by expressing latent EBV antigens such as LMP and EBNA.

- **LMP-1** (latent membrane protein-1) is the most important viral oncogene.
  - It is coated on the surface of infected cells and behaves as growth factor receptor (e.g. CD40) thus promoting proliferation of infected cells via nuclear factor κβ (NF-κβ) and *JAK/SAT* pathways.
  - It also activates anti apoptotic protein Bcl-2 and thereby prevents host cell apoptosis.
- **Viral EBNA-2** (EBV nuclear antigen-2) activates host cell *cyclin-D*, thus promotes cell proliferation.

Role of Host Immune Response

- Oncogenecity is kept under control by host immune response by producing anti LMP-1 antibodies.
- Hence, oncogenecity is markedly enhanced in immunosuppressed individuals.
- In immunocompetent individuals, B cells can still undergo malignant transformation in the presence of another pre-existing mutation, (8;14), that in turn activates the growth promoting MYC oncogene. This is typically observed in Burkitt's lymphoma affecting African children.

Clinical Manifestations

Infectious Mononucleosis

It is also called kissing disease (transmitted through salivary contact) or glandular disease.

- Age: Young adults of developed countries are usually affected.
- It is characterized by:
  - Headache, fever, malaise
  - Pharyngitis
  - Cervical lymphadenopathy
  - Hepatosplenomegaly
  - Rashes following ampicillin therapy
  - Atypical lymphocytosis (CD8 T cells)
  - Autoantibodies reactive to sheep RBC antigens (detected by Paul Bunnell test).

EBV-associated Malignancies

EBV is associated with several malignancies:

- **Burkitt's lymphoma** (tumor of the jaw seen in children and young adults): EBV is associated with 90% of African and 20% of non-African cases of Burkitt's lymphoma.
  - Most of the cases have pre-existing mutation [t(8;14)].
  - Falciparum malaria may impair host CMI and stimulates the EBV-infected B cells.
- **Nasopharyngeal Carcinoma:** It is seen among *Chinese* people who have history of intake of *salted fish* (nitrosamine) and herbal snuff (phorbol ester).
- **Hodgkin's lymphoma** (especially the mixed-cellularity type): EBV DNA is found in Reed-Sternberg cells, in at least 50% of cases of Hodgkin's lymphoma.
- **NHL (Non-Hodgkin's lymphoma):** All central nervous system non-Hodgkin's lymphomas and 50% of systemic non-Hodgkin's lymphomas are EBV positive.

Other Conditions Associated with EBV

- **Lymphoproliferative disorder** seen among immunodeficient patients, e.g. Duncan syndrome which is an X-linked recessive disease affecting young boys.
- **Hairy cell leukoplakia:** Wart-like growth of epithelial cells of the tongue developed in some HIV-infected patients and transplant recipients (Fig. 42.6).
- Chronic fatigue syndrome.

Epidemiology

EBV is worldwide in distribution.

- **Age:** EBV infections are most common in early childhood, with a second peak during late adolescence. However, infectious mononucleosis is common among young adults of developed countries.

Fig. 42.6: Oral hairy leukoplakia of the tongue

Source: Public Health Image Library, ID# 6059/Centers for Disease Control and Prevention (CDC), Atlanta *(with permission)*

- **Prevalence:** EBV is common in all parts of the world, with > 90% of adults being seropositive and develop antibodies to EBV.
- **Transmission:**
  - Intimate and prolonged oral contact is required for effective transmission. EBV is spread by direct contact with oral secretions, e.g. salivary contact during kissing.
  - Other modes are blood transfusion and following bone marrow transplantation.
- **Source:** Asymptomatic seropositive individuals shed the virus in oropharyngeal secretions. Shedding is more in immunocompromized patients.

LABORATORY DIAGNOSIS — Epstein-Barr virus

- **Antibody detection:**
  - Nonspecific heterophile antibody detection:
    - Paul-Bunnell test
    - Differential absorption test
    - Monospot test
  - EBV specific antibody detection—ELISA and indirect IF assay detecting antibody to viral capsid antigen, EBNA and early antigen
- **Molecular methods:**
  - Detects EBV DNA (by PCR)
  - Quantifies EBV DNA (by real-time PCR)
  - EBER RNA (by RT-PCR)
- **EBV antigen:** By direct IF assay
- **Virus isolation:** Not routinely preformed

Laboratory Diagnosis

Antibody Detection

Heterophile Agglutination Test

- **Paul-Bunnell test:** It is a tube agglutination test that uses sheep RBCs to detect heterophile antibodies in patient's serum.
- **Procedure:** Serial dilutions of inactivated (56°C for 30 mimutes) patient's serum are mixed with equal volumes of 1% sheep RBCs, and then the tubes are incubated at 37°C for four hours.
- **Result:** Agglutination titre of >256 is considered as significant.
- **False positive:** Heterophile antibodies are non-specific, may also be present following serum therapy or even in some normal individuals; hence confirmation is must.
- **Differential absorption test** is done for confirmation. Patient's serum is first made to react with guinea pig kidney cells and ox red cells, following which Paul-Bunnell test is repeated (Table 42.4).
- **Monospot test** is modified heterophile agglutination test available commercially.
  - It is a simple *slide agglutination test* that uses horse RBCs instead of sheep RBCs.
  - Test serum is prior treated with guinea pig kidney and ox red cells.
  - It has largely replaced the differential absorption test, and has excellent sensitivity (75%) and specificity (90%).
- Heterophile antibodies appear early (40% in first week and 80-90% in third week of illness), then disappear within 3 months.
- Heterophile antibodies are not detectable in children <5 years, in elderly or in patients with atypical symptoms.

EBV-specific Antibody Detection

Various formats such as ELISA and indirect immunofluorescence techniques are available to detect specific EBV antibodies. These tests have become more popular and are almost replacing the traditional heterophile antibody tests.

- **Antibody to viral capsid antigen** (VCA):
  - IgM type: Indicates current infection.
  - IgG type: Is a marker of past infection and indicates immunity.
- **Antibodies to early antigen (EA):** It also indicate current viral infection. They are elevated in patients with Burkitt's lymphoma or nasopharyngeal carcinoma.
  - EA-D antibody (antibody to early antigen that occurs in diffuse pattern in nucleus and cytoplasm of the infected cells) is elevated in acute infection and Burkitt's lymphoma.
  - EA-R antibody (antibody to early antigen restricted to the cytoplasm) is elevated in nasopharyngeal carcinoma.
- **Antibodies to EBNA** (Epstein-Barr nuclear antigen) reveal past infection, but four foldrise of titer may suggest current infection.

TABLE 42.4: Paul-Bunnell test and its confirmation by differential absorption test

Features	Paul-Bunnell test (performed first)	Treated with		Paul-Bunnell test (repeated)
		Guinea pig kidney cells	Ox red cells	
Infectious mononucleosis	Positive	Not absorbed	Absorbed	Serum prior treated with guinea pig kidney cells- test is positive Serum prior treated with ox red cells- Negative
Antibody after serum therapy	Positive	Absorbed	Absorbed	Negative for both sera
Normal serum	Positive	Absorbed	Not absorbed	Serum prior treated with ox red cells- test is positive Serum prior treated with guinea pig kidney cells–test is negative

Other Tests

- **Detection of EBV DNA** (by PCR), **EBER RNA** (EBV encoded small RNAs, by reverse transcriptase PCR), or **EBV antigens** (by direct-IF technique) have been useful for detecting the virus in various malignancies and in infectious mononucleosis.
- **Real-time PCR** quantifying EBV DNA load in blood is extremely useful to monitor the treatment response in patients with lymphoproliferative disease.
- **Virus isolation:** It is laborious, time-consuming (6–8 weeks) and highly sophisticated, hence not routinely performed. EBV can be isolated from saliva, blood, or lymphoid tissue. It causes immortalization of normal human B cells, obtained from cord blood.

TREATMENT **Epstein-Barr virus**

- **Supportive measures** such as analgesics are used in the treatment of infectious mononucleosis.
- **Acyclovir** is useful in the treatment of oral hairy leukoplakia, though relapse is common. It reduces EBV shedding from the oropharynx but it has no effect on the immortalized B cells, hence it is not effective for infectious mononucleosis and other malignancies.
- **Antibody to CD20** (rituximab) has been effective in some cases.

Prevention

The isolation of patients with infectious mononucleosis is not needed as temporary contact does not transmit the infection. No vaccine is currently available. A vaccine trial using EBV glycoprotein was found to be ineffective.

LESS COMMON HERPESVIRUSES

Human Herpesvirus-6

HHV-6 infects the T cells by binding to CD46 receptor. It has two variants 6A and 6B.

- **Transmission** is through infected oral secretions.
- **Sixth disease:** In children, HHV-6 (usually the 6B variant) causes sixth disease, also called as exanthem subitum or roseola infantum. It is characterized by high grade fever and skin rashes.
- In older age groups, HHV-6 has been associated with mononucleosis-like syndrome.

Human Herpesvirus 7 (HHV-7)

HHV-7 also shows tropism for T cells, transmitted by oral secretions, mainly in children.

- It shares 30–50% DNA homology with HHV-6.
- It has been associated with fever, seizures, respiratory or gastrointestinal signs, and pityriasis rosea.

Human Herpesvirus 8 (HHV-8)

HHV-8 was first discovered in 1994 in patients with Kaposi's sarcoma, hence also called Kaposi's sarcoma-associated herpesvirus (KSHV).

- **Pathogenesis:**
  - HHV-8 belongs to γ subfamily of herpesviruses and infects the B cells.
  - HHV-8 genome possesses several oncogenes that regulate certain host cell functions such as proliferation and apoptosis.
- **Epidemiology:**
  - **In high prevalence area:** HHV-8 is endemic in Africa where it is transmitted by oral secretion.
  - **In low prevalence areas** such as North America, Asia, northern Europe, it affects adults, transmitted by sexual route (homosexual men).
  - Other less common mode of transmission include-organ transplantation, injection drug abuse, and blood transfusion
- **Disease association:** In immunocompromized individuals (e.g. HIV-infected people), HHV-8 is associated with:
  - Kaposi's sarcoma (Fig. 42.7).
  - Primary effusion lymphoma (body cavity-based lymphomas).
  - Castleman's disease (lymphoproliferative disorder of B cells).
  - In immunocompetent host, HHV-8 produces fever and rash.
- **Diagnosis:** PCR detecting DNA is the most confirmatory assay. Isolation is difficult. Antibody detection assays are available in various formats such as indirect-IF, Western blot, and ELISA.

Fig. 42.7: Kaposi's sarcoma of the hard palate secondary to AIDS infection (arrow showing)

Source: Public Health Image Library, ID# 6070/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Human herpesvirus 8**

HHV-8 infections respond well to foscarnet, ganciclovir, and cidofovir. Effective antiretroviral therapy for HIV-infected individuals can reduce the risk of Kaposi's sarcoma in HHV-8 infected people.

Herpes Simian B Virus

Herpes simian B virus (formerly Cercopithecine herpesvirus-1, *Herpesvirus simiae or* B virus) is a zoonotic simplex virus infecting macaque monkeys.

- **Transmission:** Human infection is rare, occurs by (1) zoonotic spread by monkey bite (most common), or (2) rarely by respiratory route.
- It is highly pathogenic for humans, causes acute ascending myelitis and encephalomyelitis with a high mortality rate (60%).

EXPECTED QUESTIONS

I. Essay:

1. A 7-year-old boy had developed multiple painful vesicles over the lips and buccal mucosa. His parents revealed that two children of his school had a similar presentation few days back. Scraping taken from the lesion demonstrated presence of multinucleated giant cell (Tzanck cell).
   a. What is the most probable diagnosis?
   b. List the other agents causing this type of infection?
   c. How is this infection diagnosed in the laboratory?
2. Describe the pathogenesis and laboratory diagnosis of cytomegalovirus infection.

II. Write short notes on:

1. Infectious mononucleosis
2. Kaposi's sarcoma
3. Chickenpox

III. Multiple Choice Questions (MCQs):

1. A Tzanck smear of a scraping obtained from a vesicle on the skin demonstrates multinucleated giant cells. Which of the following viruses is associated with such finding:
   a. Herpes simplex type 1 virus
   b. Variola major
   c. Coxsackie virus
   d. Molluscum contagiosum

2. Which of the following viruses causes a mononucleosis-like syndrome, and also a common cause of congenital infection?
   a. Epstein-Barr virus
   b. Human herpesvirus-6
   c. Cytomegalovirus
   d. Varicella-zoster virus

3. Which of the following tumors is not caused by Epstein-Barr virus?
   a. Post-transplant lymphomas
   b. Hodgkin's disease
   c. Burkitt's lymphoma
   d. Kaposi's sarcoma

4. A 25-year-old female has developed fever, sore throat, and lymphadenopathy accompanied with atypical lymphocytosis and an increase in sheep cell agglutinins. The diagnosis is most likely:
   a. Infectious hepatitis
   b. Infectious mononucleosis
   c. Chickenpox
   d. Herpes simplex infection

5. A 48-year-old woman develops fever and focal neurological signs. MRI shows a left temporal lobe lesion. Most appropriate test that can be used to confirm the diagnosis of HSV encephalitis in this patient is:
   a. Brain biopsy
   b. Tzanck smear
   c. PCR assay for viral DNA in CSF
   d. Serum IgM antibody detection

Answers

1. a **2.** c **3.** d **4.** b **5.** c

CHAPTER 43

Other DNA Viruses

This chapter covers DNA viruses (other than Herpesviridae and Hepadnaviridae) such as:

- Parvoviridae
- Papillomaviridae and polyomaviridae
- Poxviridae
- Adenoviridae
- Bacteriophages

PARVOVIRIDAE

PARVOVIRUSES

Morphology

Parvoviruses are the simplest animal viruses infecting humans, responsible for a common childhood exanthema called as erythema infectiosum (fifth disease).

- They are the smallest viruses (18–26 nm size).
- Non-enveloped with icosahedral symmetry.
- Possess linear single-stranded DNA, comprising of about 5000 nucleotides (the only DNA virus to have ssDNA).
- Capsid is made up of 32 capsomeres.
- They depend upon the host cell enzymes for replication.

Classification

Parvoviridae family has two sub-families—Parvovirinae (infect vertebrates) and Densovirinae (infect insects).

- Parvovirinae contains three genera—*Parvovirus*, *Erythrovirus* and *Dependovirus*.
- The most pathogenic human parvovirus i.e. Parvovirus B19 belongs to the genus *Erythrovirus*.

PARVOVIRUS B19

Pathogenesis

- **Transmission:** Parvovirus B19 exclusively infects humans, most commonly by the respiratory route, followed by blood transfusion and transplacental route.
- **Infects precursors of red blood cells (RBCs):** Parvovirus B19 has a special tropism for erythroid progenitor cells present in adult bone marrow and fetal liver as it binds to blood group P antigen as receptors; which are present on the red blood cell (RBC) surface.
- **Virus induced cytotoxicity:** Results in red cell destruction and inhibition of erythropoiesis, which is profound in the presence of underlying immunosuppression and hemolytic anemia.

Clinical Manifestations

Erythema Infectiosum

- **Fifth disease:** In children, the disease is called as fifth disease; characterized by rashes on face described as **slapped cheek** appearance (Fig. 43.1).
- Adult women present with symmetrical polyarthropathy which usually involves the hand joints and knee. Rashes may or may not be present.

Transient Aplastic Crisis

It can occur in infected patients with underlying hemolytic anemia-leads to severe acute anemia.

Fig. 43.1: Fifth disease or rashes with slapped cheek appearance

Source: Wikipedia/ Andrew Kerr (*with permission*)

TABLE 43.1: Clinical manifestations and laboratory diagnosis of parvoviral infections

Syndrome	Host or Condition	Clinical Feature	Antibody	Real time PCR
Erythema infectiosum	Children (fifth disease)	Rashes with slapped cheek appearance	IgM (+ve) IgG (+ve)	$>10^3$ DNA copies/mL
	Adults	Polyarthropathy		
Transient aplastic crisis	Underlying hemolytic anemia	Severe acute anemia	IgM (-/+) IgG (-/+)	Initially $>10^{12}$ DNA copies/mL, but rapidly decreases later
Pure red cell aplasia	Underlying immunosuppression	Chronic anemia	IgM (-/+) IgG (-/+)	$>10^6$ DNA copies/mL
Hydrops fetalis	Fetus	Fatal anemia	IgM (-/+) IgG (+ve)	PCR is positive (amniotic fluid) Quantitation is not applicable

Pure Red Cell Aplasia

It can occur in those with underlying immunosuppression due to persistent B19 infections, resulting in chronic anemia.

Non-immune Hydrops Fetalis

It can occur in fetus which results in fatal anemia and fetal death. Transplacental transmission occurs in 30% of cases and maximum risk is in the second trimester (Table 43.1).

Laboratory Diagnosis

Molecular Methods

The most sensitive assay for diagnosis is polymerase chain reaction (PCR), which detects viral DNA from serum, tissue or respiratory secretions (Table 43.1).

- **Real time PCR** is used for quantification. During acute infections, viral load in the blood may reach 10^{12} DNA copies/mL.
- **Genotyping:** Parvovirus B19 has three genotypes but antigenically has single serotype. Genotype 1 is the most common one found in most parts of the world whereas genotype 3 is predominant in Western Africa.

Antibody Detection

- IgM antibody appears early, indicates recent infection and remains elevated for 2–3 months.
- IgG antibody appears late. IgG against conformational epitopes of parvovirus persists for years, but that against linear epitopes decline within months of infection Antibody may or may not be found in immunodeficient patients.

Immunohistochemistry has been used to detect viral antigens in fetal tissues and bone marrow. Parvovirus is very difficult to grow in culture.

TREATMENT **Parvovirus**

- No antiviral drug is available.
- Treatment is symptomatic.
- Immunoglobulins containing neutralizing antibodies to human parvovirus are available commercially.

OTHER PARVOVIRUSES THAT INFECT HUMANS

- **Human bocaviruses:** They have been isolated from cases with respiratory infection and gastroenteritis in children but their pathogenic role remains unclear.
- **Human dependoviruses:** They are also called as adeno-associated viruses; as they are defective and depend on adenovirus for replication. They are non pathogenic to man.

PAPILLOMAVIRIDAE AND POLYOMAVIRIDAE

Formerly, the papillomaviruses and polyomaviruses were together grouped under Papovaviridae family, but now they are separated as two different families (Table 43. 2).

- **Family Papillomaviridae:** This family has 16 genera, out of which Human papillomavirus infects man.
- **Family Polyomaviridae:** This family has several genera infecting animals. Human infections are associated with John Cunningham (JC) virus, BK virus and SV40 virus (Simian vacuolating virus 40) (Table 43.2).

HUMAN PAPILLOMAVIRUS

Human papillomavirus (HPV) has selective tropism for epithelium of skin and mucous membranes and produces an array of infections ranging from benign warts, to malignant neoplasia of cervix.

Morphology

Papillomaviruses are non-enveloped, measure 50–55 nm in size, have icosahedral capsids composed of 72 capsomeres. It contains a double-stranded circular DNA genome of 7900–8000 base pairs.

Viral Genome

Viral genome consists of an early (E) region, a late (L) region, and a noncoding regulatory region.

TABLE 43.2: Differences between Polyomaviridae and Papillomaviridae

Characteristic	Polyomaviridae	Papillomaviridae
Structure	45 nm in size, icosahedral symmetry, no envelope	55 nm in size, icosahedral symmetry, no envelope
DNA	▪ Circular, dsDNA ▪ Comprises of 5 kbp of nucleotides ▪ Both the DNA strands code for proteins.	▪ Circular, dsDNA ▪ Comprises of 8 kbp of nucleotides ▪ Coding information is present on one DNA strand
Oncogenic potential	▪ Transforms cells frequently in vitro, but rarely in vivo (natural infections)	▪ It can produce tumors in natural hosts ▪ In vitro, rarely transforms cells
Target tissue	Internal organs	Epithelium (skin and mucosa)
Viruses infecting humans and disease produced	▪ **JC virus:** Causes Progressive Multifocal Leukoencephalopathy (PML) ▪ **BK virus:** Causes nephropathy in transplant recipients. It differs from JC virus, by its ability to grow in a wide range of cell lines and is less oncogenic. (JC and BK viruses are named after the initials of the patients in whom they were described first.) ▪ **Merkel cell virus:** Causes Merkel cell carcinoma of skin ▪ **SV40 virus** (Simian vacuolating 40 virus): It is non- pathogen to man	Human papillomaviruses (>100 types) cause: ▪ Warts (skin warts and genital warts) ▪ Epidermodysplasia verruciformis ▪ Cervical carcinoma and cervical intraepithelial neoplasia (CIN) ▪ Laryngeal papillomas and carcinoma

- **Early region genes (E1-E7):** They code for early non-structural proteins. The E1 and E2 proteins modulate viral DNA replication. Products of early genes E6 and E7 have oncogenic potential by following ways-
  - *E6 protein* facilitates the degradation of the p53 tumor-suppressor protein
  - *E7 protein* binds to the retinoblastoma gene product and related proteins.
- **Late region genes (L1 and L2):** They code for structural proteins such as capsid
  - L1—codes for major capsid proteins
  - L2—codes for minor capsid proteins
- **Types:** More than 100 types of HPV are recognized based on DNA sequences of L1 region. Types differ from each other at least by more than 10% in the sequence of their L1 genes.

Pathogenesis

Human papillomaviruses typically infect skin (squamous epithelium) and mucous membranes and produce various benign and malignant lesions (Table 43.3).

Benign Warts

- Common warts (verruca vulgaris)—seen among young children.
- Flat warts (verruca plana)—are common in children.
- Plantar warts (verruca plantaris)—widely prevalent among adolescents and young adults.
- Anogenital warts (condyloma acuminatum): It is a sexually transmitted disease seen among adults (Fig. 43.2).

TABLE 43.3: Clinical features of human papillomavirus (HPV) and the types responsible for various types of lesions

Clinical Lesion	Oncogenic Potential	HPV Types
Plantar warts	Benign	1
Common skin warts	Benign	2, 4, 27, 57
Epidermodysplasia verruciformis	Mostly benign, Rarely progress to malignancy	5, 8, 9, 12, 17
Anogenital warts Laryngeal papillomas Intraepithelial neoplasia	Low malignant potential	6, 11
Palmar warts seen in butchers	Low malignant potential	7
Carcinomas of cervix and other genital mucosa/ larynx/ esophagus	High malignant potential	16, 18, 30, 31, 33 and 45

Epidermodysplasia Verruciformis

It is a rare autosomal recessive benign condition, has propensity to progress to squamous cell malignancy particularly in sun-exposed areas. Malignant transformation is common when infected with unique HPV types 5 and 8 that do not cause any other disease.

Cervix Lesions

- CIN (cervical intraepithelial neoplasia)—is a benign condition, associated with low risk HPV types 6 and 11.
- Carcinoma cervix (squamous cell)—is associated with high risk HPV types such as 16, 18, 30, 31, 33, and 45.

Figs 43.2A and B: Condyloma acuminatum. **A.** Penis; **B.** Vagina

Source: Public Health Image Library, A. ID# 3724, B. ID# 4097 /Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- High risk serotypes are associated with squamous cell carcinoma involving other genital regions such as penis, anus, vagina and vulva.

Head and Neck Lesions

- Benign lesions such as recurrent laryngeal papillomas in children are associated with low risk types 6 and 11.
- Malignant lesions such as laryngeal and esophageal carcinomas (associated with high risk types 16 and 18).

Pityriasis Versicolor Like Lesions

These type of lesions can be seen in immunosuppressed patients, particularly those who have undergone organ transplantation.

Laboratory Diagnosis

- **Molecular methods:** PCR or the hybrid capture assay can be used to detect HPV DNA and to identify specific virus types.
- Most lesions are visible to the naked eye. Solutions of **5% acetic acid** can be applied to improve visibility.
- **Cytologic evidence** of HPV infection is detected by:
  - Papanicolaou smears prepared from cervical or anal scrapings.
  - Histopathological staining of biopsies.
- **Antibody** detection is not much useful.

TREATMENT **Human papillomavirus**

- **Removal of the lesions:** Frequently used procedures for removal of lesions include cryosurgery, electrodesiccation, surgical excision and laser therapy.
- **Topical preparations** of podophyllum, interferon or imiquimod (interferon inducer) can be used for genital warts.
- Recurrence is common.

Prevention (HPV Vaccine)

Recently developed HPV vaccines have shown dramatic reduction in rates of all HPV infections including cervical cancers. It is recommended to adolescent and young adult females.

- Subunit vaccine consists of virus-like particles composed of HPV L1 proteins which are produced in yeast by DNA recombinant technology.
- Both quadrivalent and bivalent vaccines are licensed.
  - **Quadrivalent vaccine:** Includes serotype 6, 11, 16 and 18 (Gardasil, Merck).
  - **Bivalent vaccine** includes only the high risk serotype 16 and 18 (Cervarix, GlaxoSmithKline).

Barrier methods of contraception can block sexual transmission, thus prevent anogenital HPV infections.

ADENOVIRIDAE

Adenoviridae family consists of two genera:

- *Aviadenovirus:* Infects birds
- *Mastadenovirus:* Infects mammals including humans

Human adenoviruses are further serotyped into 51 distinct antigenic types which are divided into six groups (I to VI) based on the following properties:

- Ability to agglutinate RBCs from either monkeys or rats
- Oncogenic potential in animals (rats) or cell lines (they are non-malignant to humans)
- Guanine-plus-cytosine (G+C) content of DNA

Group I adenoviruses include serotypes 12, 18 and 31. They have maximum oncogenic potential, but are lowest in G+C content. It is also the only group that does not agglutinate monkey or rat RBCs.

ADENOVIRUS

Morphology

Adenoviruses have the following properties:

- They are non-enveloped, 70–90 nm in size, possess 252 capsomeres.
- Icosahedral symmetry with fiber proteins projecting from each vertex (unique property): This gives a typical **space vehicle shaped** appearance (Fig. 43.3).
- They contain a linear dsDNA.

Pathogenesis and Clinical Manifestations

Adenoviruses infect and replicate in the epithelial cells of the respiratory tract, eye, gastrointestinal tract, urinary bladder and liver. Though one-third of the serotypes can cause human diseases, **type 1–7** are the most common types worldwide. Single serotype may cause different manifestations and conversely, more than one type may cause the same clinical illness.

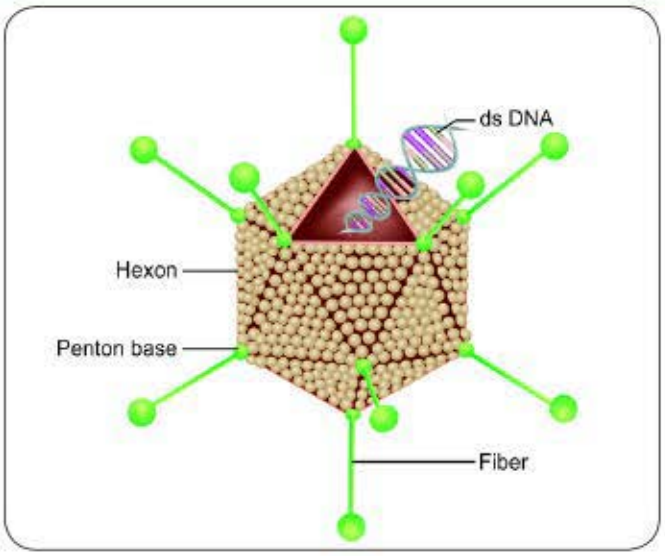

Fig. 43.3: Adenovirus (schematic diagram)

- **Respiratory diseases**
  - Upper respiratory tract infection in children—mainly caused by serotypes 1, 2, 3 and 5.
  - **Pneumonia:** Adenoviruses particularly types 3, 7, and 21 are responsible for about 10–20% of pneumonia in childhood.
  - Acute respiratory disease syndrome outbreaks among military recruit—are commonly associated with type 4 and 7.
- **Ocular infections:**
  - **Pharyngoconjunctival fever:** It tends to occur in outbreaks, at children's summer camps (also called swimming pool conjunctivitis), and is associated with types 3 and 7.
  - **Epidemic keratoconjunctivitis** or **shipyard eye:** It occurs mainly in adults and is highly contagious, caused by types 8, 19 and 37.
- **Infantile gastroenteritis:** Serotype 40 and 41 may account for 5–15% of cases of viral gastroenteritis in young children.
- **Acute hemorrhagic cystitis** in children, especially in boys- caused by serotypes 11 and 2.
- **Immunocompromised** patients are at higher risk of developing serious pneumonia.
- **Transplant recipients** may develop pneumonia, hepatitis, nephritis, colitis, encephalitis and hemorrhagic cystitis. Types 34 and 35 are isolated commonly from transplant recipients.

Laboratory Diagnosis

- **Specimen collection:** Depending on the manifestations, various specimens such as throat swab, conjunctival swab, stool or urine may be collected.
- **Virus isolation:** Primary human embryonic kidney cell line and A 549 cell line are the most susceptible cell lines. Others such as HEp-2, HeLa, and KB cell lines can also be used.
  - ***Viral growth*** can be detected by:
    - Characteristic cytopathic effect: Rounding and grape-like clustering of swollen cells.
    - Antigen detection by direct-IF test.
  - ***Reporting:*** Reporting should be done cautiously when adenovirus is recovered from throat or stool as they can persist for long duration in the gut and in adenoids and shed intermittently in the setting of other infections.
  - ***Shell vial technique*** can be performed prior to cell culture to enhance viral replication so that detection time can be reduced.
  - ***Explant culture:*** Adenoviruses (especially group-C) can grow on adenoid explants, however it is no longer in use now.
- **Serotyping:** Type specific antigens can be identified by hemagglutination test and neutralization test. PCR can also be done to detect genes coding for type-specific antigens.
- **Direct-IF test:** It can be employed to detect adenoviral antigens from clinical samples such as throat or conjunctival secretions by using fluorescent tagged anti-hexon antibody.
- **Fastidious enteric serotypes** such as type 40 and 41 from stool: They can be detected by electron microscopy or by antigen detection by ELISA.
- **PCR assays** are available targeting both group specific and type specific genes. PCR is rapid and more sensitive than conventional culture.
- **Serum antibody detection:** It can be done by various tests such as CFT, neutralization test, ELISA, or rarely hemagglutination inhibition test (HAI) for few hemagglutinating serotypes.

Treatment and Control

There is no specific antiviral drug available. Only symptomatic treatment is given.

General Preventive Measures

- Effective hand washing.
- Use of paper towels is better than cloth towels for hand drying which easily get dirty.
- Sodium hypochlorite to disinfect environmental surfaces.
- Chlorination of swimming pools and waste water should be followed to prevent waterborne conjunctivitis or gastroenteritis.
- Strict asepsis during eye examinations.

Live Adenovirus Vaccine

Live adenovirus vaccine containing types 4 and 7 has been used in military recruits.

- It was available as gelatin coated capsules and given orally.
- It was highly effective, but not in use since 1999 due to manufacturer issues. There are plans to develop this vaccines again.

Adenoviruses used for Gene Therapy

Adenoviruses can also be used as live-virus vectors for the delivery of vaccine antigens and for gene therapy.

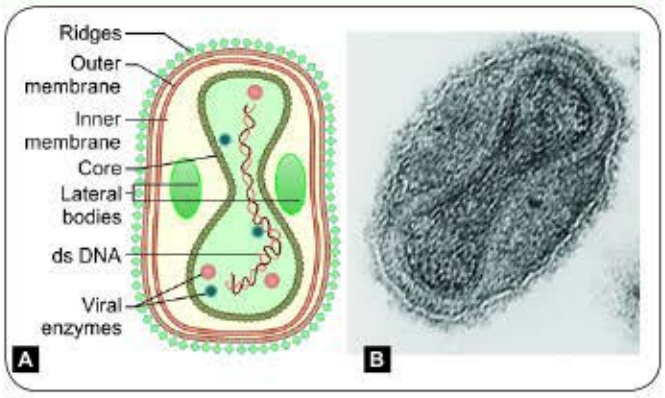
POXVIRIDAE

POXVIRUS

Morphology

Poxviruses are the largest (400 nm in length × 230 nm in diameter) among all the viruses, large enough to be seen under light microscope.

- Most complex viruses; their structure does not fit into either icosahedral or helical symmetry.
- Brick-shaped or ellipsoid.
- Envelope: Externally, there is an envelope, made up of two lipoprotein membranes (outer and inner) with ridges arising from the outer membrane. The envelope encloses a core and two structures of unknown function called lateral bodies (Figs 43.4A and B).



Figs 43.4A and B: A. Smallpox virus (schematic diagram); **B.** Smallpox virus (electron micrograph)

Source: B. ID# 1849 Dr. Fred Murphy, Sylvia Whitfield/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Core or the nuclecapsid is biconcave dumbbell shaped, surrounded by a corewall.
- Capsid is 12 nm thick, made up of more than 1000 capsomers and encloses single linear dsDNA and many enzymes including transcriptases.
- It is the only DNA virus that replicates in the cytoplasm.

Classification

Poxviruses are grouped into eight genera (Table 43.4). Species that cause human infections fall under four genera. Important members include:

TABLE 43.4: Poxviruses and associated diseases in humans

Genus	Species	Host Reservoir	Distribution	Human Disease
Orthopoxvirus	Variola	Humans	Eradicated	Smallpox (eradicated)
	Vaccinia	Humans	–	Localized skin lesions; Used for smallpox vaccination
	Monkeypox	Rodents and monkeys	Africa	Rare, smallpox-like lesions, Systemic disease
	Cowpox	Cows	Europe	Rare; localized skin lesions, occasionally systemic
	Buffalopox	Water buffalo	Indian subcontinent	Rare; localized skin lesions
	Cantagalo and Araçatuba	Cattle	South America	Rare; localized skin lesions
Parapoxvirus	Orf	Sheep and goats	Worldwide	Rare; localized skin lesions called contagious pustular dermatitis
	Pseudocowpox (Paravaccinia)	Cattle	Worldwide	Rare; localized lesions called milker's nodule
	Bovine papular stomatitis	Cattle	Worldwide	Rare; localized skin lesions
	Deerpox	Deer	Deer herds	Local pox like lesions
	Sealpox	Seals	Seal colonies	Local pox like lesions
Molluscipoxvirus	Molluscum contagiosum	Humans	Worldwide	Many benign skin nodules
Yatapoxvirus	Tanapox	Monkeys	Africa	Rare; localized skin lesion
	Yabapox	Monkeys	Unkown	Very rare and accidental; Localized skin tumors

- **Variola:** It was the causative agent of **smallpox**, the first disease to be eradicated from the world.
- **Vaccinia:** It was used before as a vaccine for smallpox.
- **Molluscum contagiosum virus:** It causes warty lesions called as molluscum contagiosum.

SMALLPOX VIRUS (VARIOLA)

Smallpox was the first disease to be eradicated from the world. It was characterized by highly contagious severe exanthema (rashes).

Smallpox Time Line

- Last natural case of variola major was seen in a Bangladeshi women in Assam in May 1975.
- Last natural case of variola minor was seen in Merca, Somalia, 26th October 1977.
- **Eradication** was declared by WHO nearly after three years of last case, i.e. on 8th May 1980.
- **Laboratory spread:** There was a small outbreak in Birmingham (1978), due to accidental spread of the virus from the virus laboratory following which stocks from most laboratories have been destroyed.
- **Maintenance:** Currently, only two laboratories still hold stocks of smallpox virus.
  - CDC (Centers for Disease Control and Prevention) Atlanta (USA).
  - Center for Research on Virology and Biotechnology, Koltsova (Russia).
- **Agent of bioterrorism:** As vaccination was stopped following eradication, people borne after 1980 are not immunized. Hence smallpox virus can be a potential agent of bioterrorism.

Reasons that Made Eradication Successful

- Variola was an exclusively human pathogen, no animal reservoir.
- Source: Patients were the only source, there were no carriers
- Case detection was easy-due to characteristic appearance of rashes (Table 43.5).
- Subclinical cases were not transmitting the disease.
- Global smallpox eradication programme was launched in 1967 by WHO (World health organization). With a strong international cooperation and intense effort; disease was wiped out nearly after 10 years.
- Highly effective live vaccinia vaccine
  - Freeze dried form was used (↑ stability).
  - Multiple puncture technique was followed to administer the vaccine by using a bifurcated needle, which was found to be simple, effective and economical.

Brief Description of Manifestations

- Portal of entry of the virus was via the mucous membranes of the upper respiratory tract.

TABLE 43.5: Differences between smallpox and chickenpox

Smallpox	Chickenpox
Incubation period: 12 days (7–17 days)	**Incubation period:** 15 days (10–21 days)
Rash: Palm, sole and extensor surface	**Rash:** Axilla and flexor surface
Rash: Deep seated and appear in single stage, evolution is slow, centrifugal distribution	**Rash:** Superficial and pleomorphic (appear in crops) evolution is rapid, dew drop rashes, centripetal distribution
Fever subsides with appearance of rash	Fever rises with each crop of rash

- Incubation period: 12 days (7–17 days).
- **Description of Rashes:** Smallpox rashes were unique in appearance and could easily be differentiated from that of chickenpox (Table 43.5).
  - Rashes were deep seated and all rashes in an area appeared in one stage, evolution was slow (Fig. 43.5).
  - Centrifugal distribution- palm and sole and extensor surface were affected first.
  - Fever subsided with appearance of rash.

Laboratory Diagnosis

- Direct detection in scrapings from rashes.
  - Intracytoplasmic inclusion bodies (Paschen bodies).
  - Electron microscopy: Brick-shaped appearance with biconcave DNA core.
- Egg inoculation: Characteristic pock formation is seen on the chorioallantoic membrane (CAM) of a chick embryo (Fig. 43.6).

Fig. 43.5: Smallpox rashes over the face

Source: Public Health Image Library, ID# 3/Centers for Disease Control and Prevention (CDC), Atlanta/Cheryl Tyron (*with permission*)

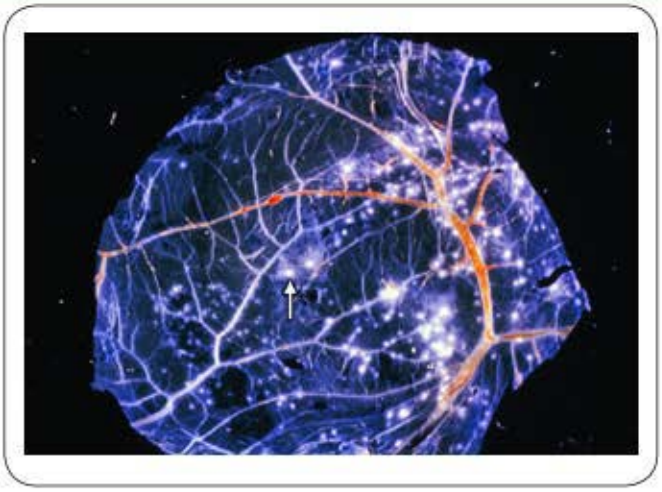


Fig. 43.6: Pocks of smallpox virus on the chorioallantoic membrane of a chick embryo

Source: Public Health Image Library, ID# 3274/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Smallpox virus (variola)**

Cases used to be treated in the past with—
- Vaccinia Immunoglobulins
- Antiviral drugs such as methisazone and cidofovir.

Vaccination

- **Live vaccinia vaccine** was highly effective.
  - It was given as single dose between 1 and 2 years of age.
  - As un-attenuated live virus was used, adverse reactions were common; such as mild vaccinia induced rashes.
- **Cowpox vaccine** discovered by Edward Jenner (the father of vaccination) was in use before vaccinia vaccine was available.
- **Variolation** was the first attempt of providing artificial immunity against smallpox. It was in use even before cowpox vaccine was available. Healthy people were inoculated with the skin scraping of a smallpox patient.

VACCINIA VIRUS

Vaccinia cross-reacts with variola and the antibodies produced against vaccinia are protective for variola. The antigenic cross reactivity was so much that vaccinia was able to eradicate variola globally.

However, vaccinia differs from variola in many ways as follows:

- It is non-pathogenic to humans or produces milder skin lesions.
- Produces an inclusion body called Guarnieri body (variola produces Paschen body).
- On CAM, vaccinia virus produces larger and hemorrhagic and necrotic pock lesions than variola.
- **Ceiling temperature:** It is the highest temperature beyond which the pock formation is inhibited on CAM. It is higher for vaccinia virus (41°C) than for variola virus (38°C).
- Vaccinia but not variola can produce plaques on chick embryo tissue cultures.

MOLLUSCUM CONTAGIOSUM VIRUS

Molluscum contagiosum virus is an obligate human poxvirus that produces characteristic skin lesions.

Clinical Manifestations

- **Lesions:** It produces pink pearly wart-like lesions (2–5 mm size), umbilicated, with a characteristic dimple at the center (Fig. 43.7A). Lesions are characterized by:
  - Lack of associated inflammation and necrosis
  - Found singly or in clusters
  - Distribution: Lesions are found anywhere on the body except on the palms and soles. Genital lesions are seen in adults.
- **Transmission:**
  - Children are commonly affected, acquire infection by direct and indirect contact (e.g. by barbers, common use of towels, swimming pools).
  - Rarely sexual transmission has been reported in young adults.
- **Self-limiting:** Lesions disappear in 3–4 months. There are no systemic complications, but sometimes, lesions may persist for 3–5 years.
- **In HIV-infected patients:** Disease is more generalized, severe and persistent.

Laboratory Diagnosis

- **Molluscum bodies** are the intracytoplasmic eosinophilic inclusions seen in skin scrapings stained with histopathological stains (Fig. 43.7B).
- Electron microscopy and PCR can be used for confirmation.
- **Not cultivable:** It cannot be propagated in tissue culture, egg or in animals.

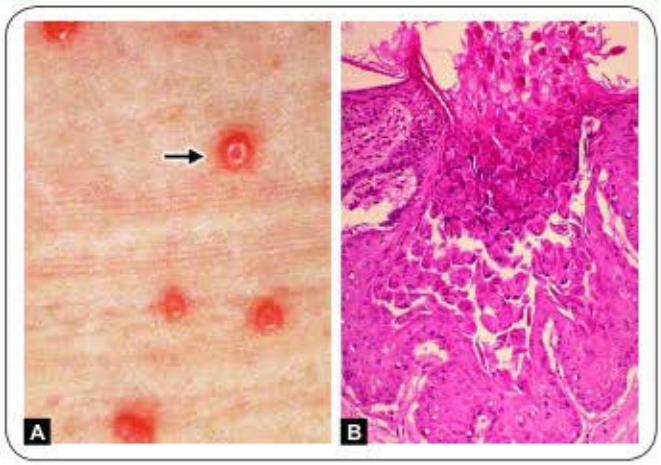
TREATMENT **Molluscum contagiosum**

Surgical removal of the lesions by ablation is the only way of treatment. Cidofovir has shown to have some efficacy. As this virus does not cross-react with any other poxviruses, smallpox vaccine is not protective.

OTHER POXVIRUSES OF HUMAN IMPORTANCE

Monkeypox Virus

- **Reservoir:** Rodents are the primary reservoirs followed by monkeys.



Figs 43.7A and B: A. Molluscum contagiosum lesions on skin; **B.** Histopathology of skin showing molluscum bodies

Source: A. CDC/ L. Sperling, MD, Walter Reed Army Medical Center; B. Public Health Image Library, ID# 860/Centers for Disease Control and Prevention (CDC), Atlanta/ Dr. Edwin P. Ewing, Jr (*with permission*)

- **Distribution:** Cases typically occur in Africa.
- **Transmission:** It is by direct contact with infected animals. Human-to-human propagation is rare.
- **Manifestation:** It is characterized by a vesicular rash similar to those of smallpox but milder. Systemic illness like fever and lymphadenopathy may be seen.
- The first outbreak occurred in USA, 2003 where more than 70 cases were reported. Transmission was linked to contact with pet prairie dogs who acquired the infection from rodents.
- Smallpox vaccination can protect against monkeypox infection.

Orf Virus

This virus affects sheep and goats. Human infections are rare; characterized by localized skin lesions, called as contagious pustular dermatitis or mouth sore.

Pseudocowpox (Paravaccinia Virus)

This virus affects cattle, can rarely infect milk handlers to produce nodular skin lesions called **milker's nodule**.

Cowpox and Buffalopox Virus

This virus can cause rare zoonotic infections in humans, characterized by pox-like lesions and mild systemic illness.

Tanapox Virus

This virus was named after its place of discovery (Tana river, Kenya). It causes nodular lesion on the exposed area after contact with infected monkeys.

BACTERIOPHAGE

Bacteriophages are the viruses that infect bacteria. It was first described by Twort and d'Herelle (1917).

MORPHOLOGY

Bacteriophages are typically tadpole-shaped possessing a hexagonal head and a tail attached with tail fibers (Fig. 43.8A).

- **Head** is hexagonal in shape, 28 nm to 100 nm in size and consists of a tightly packed nucleic acid core (containing a dsDNA) enclosed by a capsid protein coat.
- **Tail** is composed of a hollow core surrounded by a contractile sheath ending in a base plate from which six tail fibers arise.
- Altered morphology may be seen in some phages:
  - Shape-spherical or filamentous instead of hexagonal.
  - Nucleic acid—may contain ssDNA or RNA instead of dsDNA.

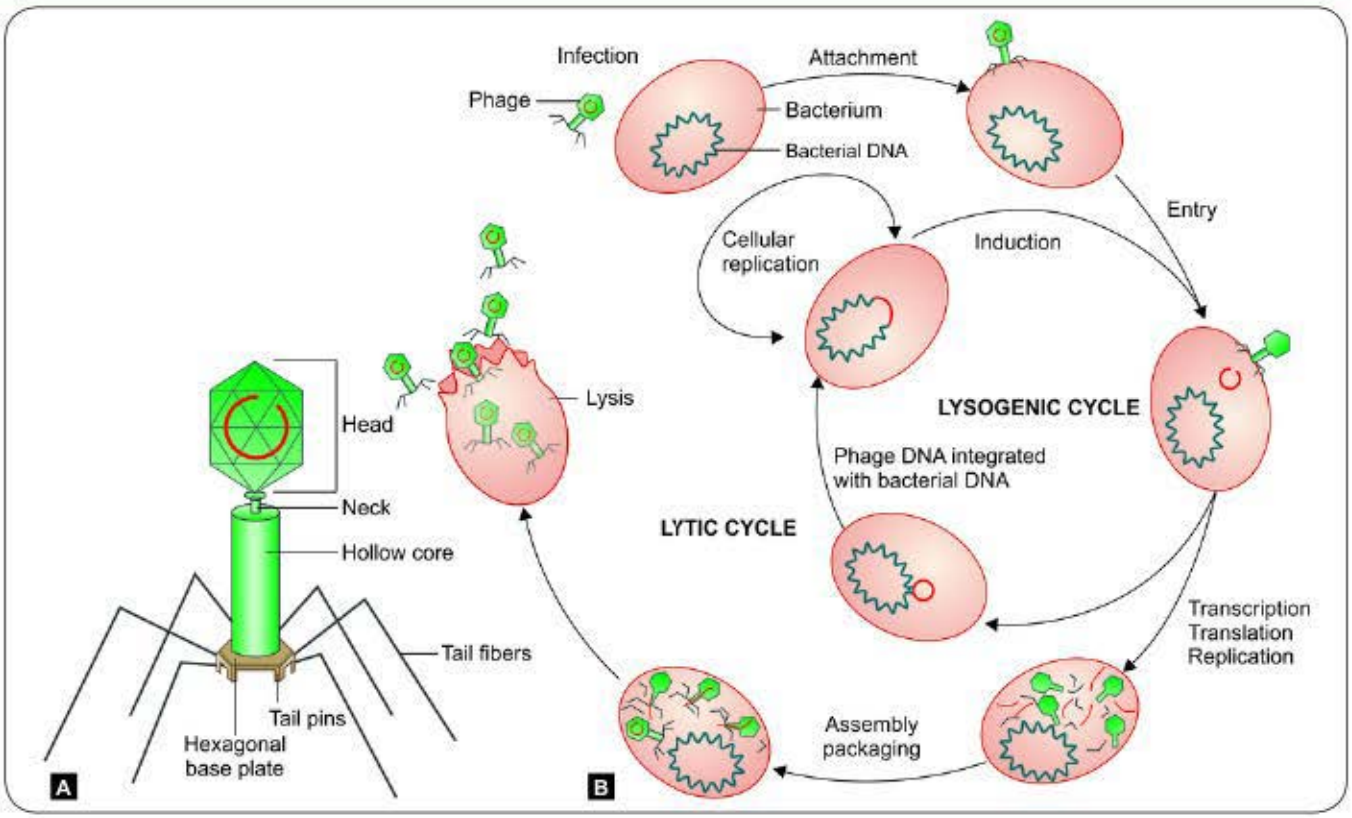
LIFE CYCLE

Bacteriophages exhibit two different types of life cycles-virulent or lytic cycle and temperate or lysogenic cycle.

Lytic Cycle or (seen in Virulent Phages)

It resembles with the replication of other DNA viruses; consists of the following steps (Figs 43.8B).

- **Adsorption:** The phages come into contact with bacterial cells by random collision and attach to specific receptors on bacterial cell wall by means of tail fibers.
  - Adsorption is an essential step to initiate the life cycle.
  - Transfection: Experimentally, bacteria may be infected by direct injection of naked phages (nucleic acid without capsid).
- **Penetration:** Phage acts as piston or a syringe, injects the dsDNA through the hollow core which is helped by the contractile sheath present in tail region.
  - Lysozyme present on tail tip makes a hole on the bacterial cell wall.
  - The empty phages remain outside, attached to bacterial cell wall as 'ghosts', hence there is no uncoating step needed, as seen with other viruses.
- **Biosynthesis:** Phage components such as dsDNA and capsid proteins are synthesized. Bacterial metabolism remains inhibited during the entire process.
- **Maturation and assembly:** Phage DNA, head and tail proteins are assembled to form infective daughter virions.
- **Release** of the daughter phages occurs by lysis of the bacterial cell which is mediated by phage enzymes.
- **Duration of eclipse phase** is about 15–30 minutes. It is the interval between entry of phage DNA and the appearance of first infectious phage particle inside the host cell. During this period, phages are not detected.



Figs 43.8A and B: A. Morphology of bacteriophage; **B.** Life cycle of a bacteriophage (Lytic and lysogenic cycles)

Lysogenic Cycle or (seen in Temperate Phages)

After the entry into bacteria, the temperate phage DNA gets integrated into the bacterial chromosome (Fig. 43.8B).

- The integrated phage genome is called the **prophage**.
- The bacterium that carries a prophage is known as a **lysogenic bacterium**.
- **Lysogeny:** The prophage behaves like a segment of the host chromosome and replicates synchronously with it. This phenomenon is called lysogeny.
- **Lysogenic conversion:** During the integrated state, the phage DNA confers certain new properties to the bacteria (e.g. provides gene for toxin synthesis).
- **Super-infection immunity:** A lysogenic bacterium is resistant to reinfection by the same or related phages.
- **Lysogenic to lytic interconversion:** Temperate phages remain integrated into the bacterial chromosome. But when they want to come out, they get excised from bacterial chromosome, then transform to lytic phages, multiply in the cytoplasm and are released by lysis.

Significance/Uses of Bacteriophages

Phage Typing

The virulent phages can be used for further classifying the bacteria beyond the species level.

- This helps in epidemiological investigations during outbreak to know the relatedness between the strains of the same species.
- Procedure: It is explained in detail in Chapter 21.
- Phage typing is employed for typing the following bacteria.
  - *Staphylococcus aureus*
  - Vi antigen typing of *Salmonella* Typhi
  - *Vibrio cholerae* (Basu Mukherjee phage typing)
  - *Brucella* (Tbilisi phage typing)
  - *Corynebacterium diphtheriae*

Phage Assay

- When virulent phages are spread over a lawn culture of a susceptible bacterium, areas of clearing or lysis called **plaques** develop surrounding the growth of each phage.
- A single phage is capable of producing one plaque. Plaque assay can be employed to estimate the number of viable phages in a preparation.

Used in Treatment (Phage Therapy)

- Lytic phages can kill the bacteria, hence may be used for treatment of bacterial infection.

- Studies are under trial for using lytic phages to treat various bacterial infections such as post-burn infections and wound infections.

Used in Diagnosis

Mycobacteriophages are used for the identification of *Mycobacterium tuberculosis*.

Used as a Cloning Vector

Bacteriophages have been used as cloning vectors in recombinant DNA technology.

Transduction

Temperate phages can act as vehicles in transferring genes from one bacterium to another.

- This may be an important method to transfer drug resistant genes between bacteria
- Example: In *Staphylococcus aureus*, the plasmids coding for β lactamases are transferred between the strains by transduction.

Code for Toxins

The phage genomes code for the following bacterial toxins:

- Diphtheria toxin
- Cholera toxin
- Verocytotoxin of EHEC (Enterohemorrhagic *E. coli*)
- Botulinum toxin C and D
- Streptococcal pyrogenic exotoxin A and C.

Alter Antigenic Property of Bacteria

The temperate phages of some salmonellae can modify the antigenic properties of the somatic O antigen. e.g., *Salmonella* Anatum changes to *Salmonella* Newington after acquiring its bacteriophage which alters the antigenic property of O antigen.

EXPECTED QUESTIONS

I. Write short notes on:

1. Fifth disease
3. Smallpox eradication
3. Manifestations produced by Adenovirus
4. HPV vaccine
5. Uses of bacteriophages

II. Multiple Choice Questions (MCQs)

1. All of the following are clinical manifestations of Parvovirus B19 infection except:
   a. Erythema infectiosum
   b. Transient aplastic crisis
   c. Condyloma acuminata
   d. Hydrops fetalis

2. All of the following are clinical manifestations of HPV except:
   a. Plantar and palmar warts
   b. Epidermodysplasia verruciformis
   c. Carcinoma of cervix
   d. Slapped cheek appearance

3. Which of the following adenovirus serotypes causes epidemic keratoconjunctivitis?
   a. Serotypes 3 and 7
   b. Serotypes 8, 19, and 37
   c. Serotypes 40 and 41
   d. Serotypes 11 and 21

4. All the following statements are true for the poxvirus except:
   a. It is a large brick-shaped virus
   b. The genome consists of a large ds linear DNA
   c. Replication cycle of the virus occurs in the nucleus of the host cell
   d. It is large enough to be seen under light microscopy

5. Phage typing is employed for typing of following bacteria except:
   a. *Staphylococcus aureus*
   b. *Vibrio cholerae*
   c. *Streptococcus*
   d. *Brucella*

CHAPTER 44

Myxoviruses and Rubella Virus

Chapter Preview

- Orthomyxoviridae
  - Influenza virus
- Paramyxoviridae
  - Parainfluenza virus
  - Mumps virus
  - Measles virus
  - Nipah virus and Hendra virus
  - Respiratory syncytial virus
  - Metapneumovirus
- Rubella virus

Myxoviruses are a group of viruses that bind to mucin receptors on the surface of RBCs (*myxo* in Greek meaning 'mucin'); resulting in clumping of RBCs together to cause hemagglutination.

CLASSIFICATION

Myxoviruses are divided into two families—(1) Orthomyxoviridae and (2) Paramyxoviridae. Both differ from each other in various aspects (Table 44.1); the most important difference is the presence of segmented RNA in Orthomyxoviridae family.

TABLE 44.1: Differences between Orthomyxoviridae and Paramyxoviridae

Properties	Orthomyxoviridae	Paramyxoviridae
Size	80–120 nm	100-300 nm
Shape	Spherical; Rarely filamentous	Pleomorphic
Nucleic acid	▪ Negative sense ssRNA, ▪ Segmented; eight pieces	▪ Negative sense ssRNA ▪ Un-segmented; single piece
Genetic recombination	Seen	Not seen
Antigenic variation	Seen	Not seen
Site for RNA Replication	Nucleus	Cytoplasm
Important human pathogens	Influenza virus	▪ Parainfluenza virus ▪ Mumps virus ▪ Measles virus ▪ Respiratory syncytial virus ▪ Metapneumovirus

Abbreviations: ss, single stranded; RNA, ribonucleic acid

ORTHOMYXOVIRIDAE

Influenza viruses are the members of Orthomyxoviridae family. They are one of the major causes of morbidity and mortality and have been responsible for several epidemics and pandemics of respiratory diseases in the last two centuries.

INFLUENZA VIRUSES

Influenza viruses consist of thee genera—influenza A, B, and C.

Morphology (Fig. 44.1)

Spherical: Influenza viruses are spherical in shape, 80–120 nm in size.

- **Helical symmetry:** It comprises of a helical nucleocapsid (9nm), surrounded by an envelope.
- **Viral RNA** comprises of **multiple segments** of (-ve) sense ss stranded RNA. Each segment codes for a specific viral protein (Table 44.2) having a specific function.
  - Influenza A and B contain **eight segments** of RNA.
  - Influenza C contains seven segments of RNA. The segment coding for neuraminidase is absent.
- **Site of replication:** RNA replication occurs typically in the nucleus(in contrast to most other RNA viruses which replicate in the cytoplasm).
- **Viral proteins:** Influenza virus contains eight structural proteins (PB1, PB2, PA, NP, HA, NA, M1 and M2) and two non-structural proteins (NS1 and NS2) (Table 44.2).
  - **PB1, PB2, and PA** are the polymerase proteins responsible for RNA transcription and replication.
  - **Nucleoprotein (NP)** is the major capsid protein, associated with viral RNA to form a ribonucleoprotein (RNP) or nucleocapsid with a helical symmetry.

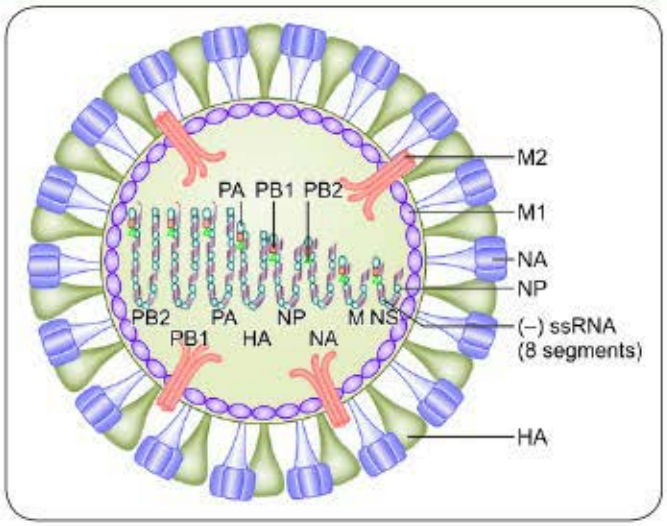

Fig. 44.1: Influenza virus (schematic diagram)

TABLE 44.2: Influenza virus RNA segments and coded proteins

RNA segments	Coded protein(s)	Function of proteins
Segment-1	PB2	RNA Transcription and replication
Segment-2	PB1	
Segment-3	PA	
Segment-4	HA (hemagglutinin)	Binds to receptors of RBC to cause hemagglutination.
Segment-5	NP (nucleoprotein)	Associates with RNA to form helical nucleocapsid
Segment-6	NA (neuraminidase)	Replaces HA from RBCs to cause elution (reversal of hemagglutination)
Segment-7	M1 and M2	M1-forms a shell underneath the envelope M2-forms ion channels
Segment-8	NS1 and NS2	NS1-is interferon antagonist and inhibits pre-mRNA splicing NS2-is nuclear export factor

- **Matrix proteins: M1 protein** is the major viral protein (40% of total protein). It forms a shell (protein layer) underneath the envelope. **M2 proteins** form ion channels in the envelope, help in transport of molecules.
- **Non-structural proteins: NS1** is an interferon antagonist and inhibits pre-mRNA splicing. **NS2** helps in export of molecules across the nucleus.
- **Hemagglutinin (HA) and Neuraminidase (NA)** are the glycoproteins inserted into the lipid envelope.

- **Envelope:** Envelope is lipoprotein in nature. Lipid part is derived from the host cell membrane. Proteins or the peplomers are virus coded, 10 nm long glycoproteins that are inserted into the lipid envelope. Two peplomers are present:
  1. **Hemagglutinin (HA):** It is triangular shaped peplomer, binds to mucin or sialic acid receptors on RBCs, resulting in clumping of RBCs to cause **hemagglutination.** It also binds to the same receptors on the respiratory epithelial cells, thus facilitating viral entry.
  2. **Neuraminidase (NA):** It is mushroom-shaped peplomer, present in fewer number than HA. It is a sialidase enzyme that degrades the sialic acid receptors on RBCs; thus helps in:
     - It displaces HA from RBCs resulting in reversal of hemagglutination called **elution**.
     - It facilitates release of virus particles from infected cell surfaces during budding process by preventing self-aggregation of virions to the host cells.
     - NA helps the virus to pass through the mucin layer in the respiratory tract to reach the target epithelial cells.

Antigenic Subtypes and Nomenclature

- **Three genera:** Based on RNP and M proteins, influenza viruses are divided into three genera: A, B and C.
- **Subtypes:** Based on HA and NA antigens,
  - Influenza A has distinct 16 H subtypes (H1 to H16) and 9 N subtypes (N1-N9).
    - Most of the sub types infect animals and birds, but occasionally undergo genetic changes and infect humans to cause major epidemics and pandemics.
    - Example—Four HA (H1, H2, H3 and H5) and two NA (N1 and N2) subtypes have been recovered from humans.
  - Influenza B and C viruses though have subtypes; but are not designated.
- **The standard nomenclature system for influenza virus:** Any influenza virus isolates should be designated based on the following information: Influenza virus Type/ host (indicated only for non-human origin)/ geographic origin/strain number/year of isolation/(HA NA subtype). For examples:
  - **Human strain:**
    Influenza A/Hong Kong/03/1968 (H3 N2).
  - **Nonhuman strain:**
    Influenza A/swine/Iowa/15/1930 (H1 N1).

Antigenic Variation

Antigenic variation is the unique property of influenza viruses, which is due to the result of antigenic changes occurring in HA and NA peplomers. It is of two types:

1. Antigenic Drift

It is a minor change occurring due to **point mutations** in the HA/NA gene, resulting in alteration of amino acid sequence of the antigenic sites on HA/NA, such that virus can escape recognition by the host's immune system. The new variant must sustain two or more mutations to become epidemiologically significant.

- Seen in both influenza virus type—A and B.
- Results in outbreaks and minor periodic epidemics.
- Antigenic drift occurs more frequently, every 2–3 years.

2. Antigenic Shift

It is an abrupt, major drastic, discontinuous variation in the sequence of a viral surface protein (HA/NA), that occurs due to **genetic reassortment** between genomes of two or more influenza viruses infecting the same host cells, resulting in a new virus strain, unrelated antigenically to the predecessor strains.

- Occurs only in influenza A virus.
- Results in pandemics and major epidemics- e.g. H1N1 pandemics of 2009.
- Antigenic shift occurs less frequently every 10–20 years.

Pathogenesis

- **Transmission:** It is via infected aerosols generated by coughs and sneezes, rarely via contacts, or by fomites. Small-particle aerosols (<10μm) are more efficient in the transmission.
- **Target cell entry:** Viral HA attaches to specific sialic acid receptors on the host cell surface that leads to viral entry. Ciliated columnar epithelial cells are most commonly infected, but it may also infect other cells including alveolar cells, mucous gland cells, and alveolar macrophages.
- **Multiply locally:** Virus replicates in the infected cells and infectious daughter virions spread to the adjacent cells to involve large number of respiratory epithelial cells over several hours.
- **Spread:** Very rarely, virus spreads to the lower respiratory tract or spills over blood stream to involve extra pulmonary sites.
- **Local damage:** Influenza virus infection causes cellular destruction and desquamation of superficial mucosa of the respiratory tract; but it does affect the basal layer of the epithelium.
  - Edema and mononuclear cell infiltrations occur at local site leading to cytokine influx, which accounts for local symptoms.
  - Local damage predisposes to secondary bacterial invasion.

Host Immune Response

Humoral immunity: It is the predominant immunity that provides resistance against influenza infections. Immunity developed is both type and subtype-specific and long lasting.

- Antibodies against HA and NA are protective in nature, as well as are subtype specific.
- Antibodies to HA prevent initiation of infection by inhibiting viral entry; whereas antibodies to NA decrease the severity of the disease and prevent the transmission of virus to contacts.
- Antibodies against other viral proteins are not protective.
- Antibodies against the ribonucleoprotein are type-specific and are useful in typing viral isolates as influenza A or B or C.
- All the three types of influenza viruses (i.e. A, B and C) are antigenically unrelated and there is no cross-protection.
- Immunity may be incomplete, as reinfection with the same virus can occur.
- **Original antigenic sin:** When a previously infected individual gets a repeated infection with a different antigenic variant of influenza virus, antibodies are produced against both the subtypes, but predominant response would be against the original strain, a phenomenon called "original antigenic sin."

Components of both cell mediated immunity (e.g. cytotoxic T cells) and innate immunity (NK cells, interferons) are also important in providing immunity against influenza infections.

Clinical Manifestations

Incubation Period

It is about 18–72 hours, which directly depends upon the inoculum size and the immune status of the host.

Uncomplicated Influenza (Flu Syndrome)

Majority of individuals are either asymptomatic or develop minor upper respiratory symptoms such as chills, headache, and dry cough, followed by high grade fever, myalgia and anorexia. It is a self-limiting condition, indistinguishable from the infections caused by other upper respiratory tract pathogens.

Complications

- **Pneumonia:** Secondary bacterial pneumonia is the most common complication to occur in patients infected with influenza virus. Common agents are staphylococci, pneumococci and *Haemophilus influenzae*. Primary influenza pneumonia is rare but leads to more severe complication.
- **Other pulmonary complications** include worsening of chronic obstructive pulmonary disease, exacerbation of chronic bronchitis and asthma.
- **Reye's syndrome:** It is fatty degeneration of liver with acute encephalopathy occurring in children and adolescents (2 to 16 years of age) following aspirin or salicylate intake. Though the cause is unknown,this condition is often seen following influenza B, varicella-zoster and rarely influenza A viral infections. The mortality rate is high (10–40%).

- **High risk groups:** The following are at increased risk of complications associated with influenza virus infection.
  - Age: children (<2 years) and old age (> 65 years).
  - Pregnancy
  - Underlying chronic lung, cardiac, renal, hepatic, and CNS conditions.
  - Low immunity (HIV infected people).
  - Older children are at high risk of developing croup, sinusitis, otitis media, high-grade fever, and diarrhoea.

LABORATORY DIAGNOSIS — Influenza virus

- **Specimen:** Nasopharyngeal swab, kept at 4°C
- **Isolation of virus:**
  - Inoculation in embryonated eggs and primary monkey kidney cell lines.
  - Growth is detected by hemadsorption, hemagglutination test.
- **Viral antigens** detection by direct IF test.
- **Molecular methods:**
  - RT PCR- detects viral RNA
  - Real time-RT PCR – quantifies viral RNA
- **Antibody detection** by hemagglutination inhibition test, neutralization test and ELISA

Laboratory Diagnosis

Specimen Collection

- **Ideal specimens** are nasopharyngeal swab, nasal aspirate or to less extent throat swab.
- **Swabs** with a synthetic tip (e.g. polyester or Dacron swabs) are best for specimen collection. Cotton or alginate swabs are unsatisfactory.
- **Transport:** Swabs are immediately put inside the viral transport media, kept at 4°C during transport up to 4 days, thereafter at –70°C.

Isolation of Virus

Embryonated eggs and primary monkey kidney cell lines have been the methods of choice for the isolation of influenza viruses. Amniotic cavity of the egg is the preferred site for inoculation as it supports all the three types of influenza virus A, B, C compared to allantoic cavity that supports only influenza A virus.

Detection of Viral Growth in Embyonated egg or Cell Line

- **Hemadsorption test:** It is done to detect the adsorption of RBCs onto the surfaces of infected cell lines that are coated with viral HA antigen; within 3–5 days after inoculation.
- **Hemagglutination:** Detects HA antigens in the culture fluid after 5–7 days of inoculation by adding fowl and guinea pig RBCs.
  - Type A virus: Agglutinates guinea pig RBCs.
  - Type B: Agglutinates both guinea pig and fowl RBCs.
  - Type C: Agglutinates fowl RBCs at 4°C.

Direct Immunofluorescence Test

Viral antigens coated onto epithelial cells can be directly detected in nasal aspirates by using fluorescent tagged antibodies. This is rapid, but less sensitive than viral isolation.

Molecular Methods

- **Reverse transcriptase polymerase chain reaction (RT-PCR)** is the most sensitive, specific and rapid method for influenza diagnosis. It is also type and subtype specific as it detects specific HA and NA genes.
- **Real time-RT PCR** can be used to quantitate the viral load in the clinical sample. Specific real time RT-PCRs have been designed for the diagnosis of avian flu (H5N1) and H1N1 flu infections.

Antibody Detection (Serology)

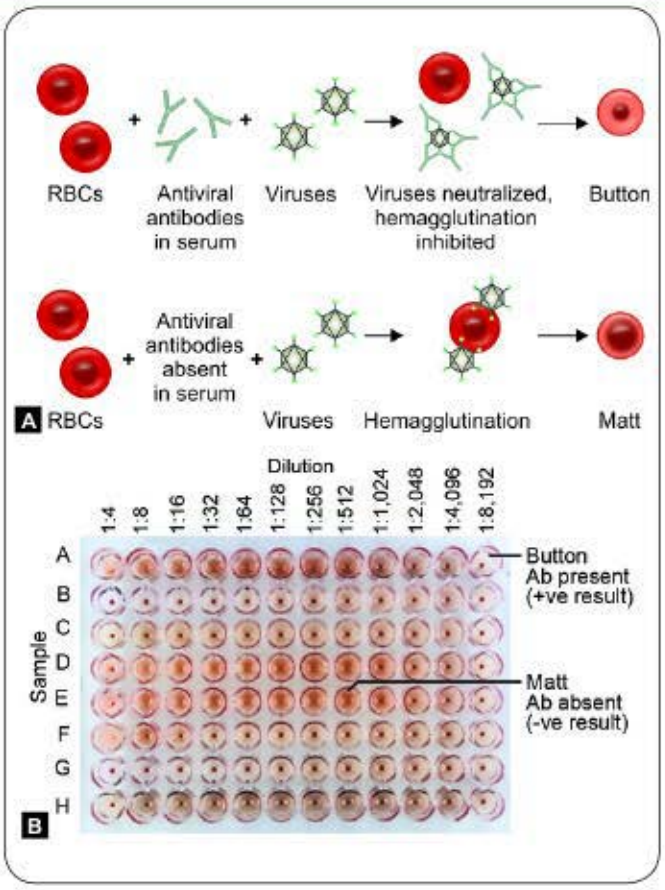
Various assays are available to detect serum antibodies by using specific influenza antigens. Fourfold rise in the antibody titer between acute and convalescent sera is more significant than a single high titer, as antibodies may be present in normal individuals. The tests available are:

- **HAI test (Hemagglutination inhibition):** Serially diluted patient's serum is incubated with influenza antigen and RBCs in a microtiter plate (Figs 44.2A and B).
  - Hemagglutination would be inhibited if the homologous antibody is present in patient's sera against which the antigen is added.
  - So, addition of the correct antigen is crucial for the test to be positive.
  - More so, nonspecific inhibitors; e.g. mucoprotein present in sera must be destroyed before performing the test.
- **Neutralization test:** Though it is the most specific and the best predictor of susceptibility to infection, is time-consuming and difficult to perform.
- **ELISA** is more sensitive than other assays.

TREATMENT — Influenza viruses

Specific antiviral therapy is available for influenza virus infection

- **Neuraminidase inhibitors** (such as zanamivir, oseltamivir, and peramivir) can be administered for influenza A and influenza B infections.
  - It is the drug of choice for A/H1N1 2009 flu, A/H5N1 avian flu and influenza-B.
  - Dosage:
    - Oseltamivir (Tamiflu 75mg tablets)
    - Zanamivir (10 mg, inhalational form)
  - Schedule:
    - For treatment—given twice a day for 5 days
    - For chemoprophylaxis—given once daily. Duration depends on the clinical setting.
- **Matrix protein M2 inhibitor** such as amantadine and rimantadine can be given for some strains of influenza A infection. However, strains of A/H1N1 2009 flu and A/H5N1 avian flu and influenza B virus have developed resistance.



Figs 44.2A and B: Hemagglutination inhibition test

Prophylaxis (Vaccination)

Vaccine strains: Based on WHO recommendations, influenza vaccines are prepared every year.

- **Strains** to be included in the vaccine depend upon the strains isolated in the previous influenza seasons and strains that are anticipated to circulate in the upcoming season.
- **Trivalent form:** Most of the influenza vaccines are cocktails containing one or two type A viruses and a type B influenza virus.
- **Types:** Both inactivated (killed) and live attenuated vaccines are available.

Inactivated Vaccines

Inactivated vaccines are the most widely used vaccines in immunization programmes.

- **Preparation:** The recommended vaccine strains are grown in allantoic cavity of embryonated chick eggs and then harvested, purified, inactivated by formalin or beta propiolactone and then standardized based on hemagglutinin antigen content (15 μg of HA/dose).
- Single dose is administered by intramuscular (IM) or subcutaneous (SC) route.
- **Protective value** of the vaccine is about 50–80% if the vaccine virus and the currently circulating viruses are closely related. Immunity lasts for 6-12 months.
- Mild reactions can occur in 5% of cases.
- **Indication:** Annual inactivated influenza vaccination is recommended for high-risk groups (as mentioned earlier).
- **Contraindication:** Inactivated vaccines should not be administered to people who have allergy to eggs or have history of hypersensitivity to previous dose of vaccine.
- **Inactivated vaccines are of three types:** All are efficacious.
  - **Whole virus (WV) vaccine:** Contains intact, inactivated viruses;
  - **Subvirion (SV) vaccine:** Contains purified virus disrupted with detergents;
  - **Surface antigen** vaccines contain purified HA and NA glycoproteins.

Live Attenuated Cold Adapted Influenza Vaccine

This vaccine is generated by reassortment between currently circulating strains of influenza A and B virus with a **cold-adapted attenuated master strain** which can grow at 33°C (upper respiratory tract) but not at 37°C (lower respiratory tract).

- Such live attenuated strains may cause mild flu like symptoms but never infect lower respiratory tract, hence never cause serious adverse effects.
- It is a trivalent vaccine, administered by intranasal spray.
- **Indication:** Live vaccine is recommended to all healthy persons of 2–49 years age (except in pregnancy), but is not given to high risk groups.

Epidemiology

Influenza outbreaks occur worldwide almost every year, however they differ widely in severity and the extent of spread.

- **Incidence:** It is estimated that annually about 3–5 million cases of severe illness and 2.5–5 lakhs of deaths occur due to influenza epidemics worldwide and is associated with significant economic impact.
- **Seasonality:** Influenza outbreaks are common during winters.The most common seasonal flu strain varies from season to season and from place to place (e.g. H3N2 in Pondicherry in 2014).
- **Epidemiological pattern:** It depends upon the nature of antigenic variation that occurs in the influenza types (as described earlier).

TABLE 44.3: Major influenza outbreaks

Years	Subtype	Extent of Outbreak
1889–1890	H2N8	Severe pandemic
1900–1903	H3N8	Moderate epidemic
1918–1919	H1N1[a] (HswN1) (Spanish flu)	Severe pandemic
1933–1935	H1N1[a] (H0N1)	Mild epidemic
1946–1947	H1N1	Mild epidemic
1957–1958	H2N2 (Asian flu)	Severe pandemic
1968–1969	H3N2 (Hong Kong flu)	Moderate pandemic
1977–1978[b]	H1N1 (Russian flu)	Mild pandemic
2009–2010	H1N1	Pandemic

[a]Hemagglutinins formerly designated as Hsw and H0 are now classified as variants of H1.
[b]From this time until 2008–2009, viruses of the H1N1 and H3N2 subtypes circulated either in alternating years or concurrently.

History of Influenza Outbreaks

Till now several influenza pandemics and major epidemics have occurred worldwide(Table 44.3).

- **Seroarchaeology:** The outbreaks that occurred prior to influenza isolation (influenza isolated first in 1933 using ferrets) were detected later by retrospective serologic survey of individuals alive during those years.
- **The severe most pandemic** (Spanish flu) recorded so far was the swine flu strain H1N1 in 1918–1919, where >50 million people died, mostly due to secondary bacterial pneumonia. This strain was not a reassortant, but believed to be derived entirely from an avian strain that had adapted to human conditions and pigs acted as a mixing vessel.
- This was followed by series of several epidemics and pandemics as mentioned in Table 44.3.

Sialic Acid Receptors

Sialic acid receptors found on the host cell surfaces are specific for HA antigens of influenza which in turn determines the different host specificities of influenza virus.

- **α 2–6 sialic acid receptors** are specific for human influenza strains and are found abundantly on human upper respiratory tract epithelium, but not on lower respiratory tract. This explains why most human flu strains cause mild upper respiratory tract infections but not pneumonia.
- **α 2–3 sialic acid receptors** are specific for avian influenza strains and are found abundantly on bird's intestinal epithelium.
  - In humans, they are present in very few numbers on upper respiratory tract, and also on some epithelial cells in the lower tract.
  - This explains why avian flu strains cannot easily infect humans and need close contact. However, once infected, they can infect lower respiratory tract and cause pneumonia.

Contd...

Contd...

Why pigs are the most common mixing vessels?

- Both α 2–3 and α 2–6 sialic acid receptors are found on the same respiratory epithelial cells of pigs and swine flu strains have specificity for both the receptor types.
- Hence pigs can be infected simultaneously by human, swine and avian strains, thus serving as a mixing vessel.
- Reassortment between the segments of various strains can take place inside the same swine cell.

Avian Flu

Birds are the primary reservoir for influenza viruses.

- All influenza subtypes (16H types and 9N types) are found in birds and some of the subtypes can be transmitted to mammals (e.g.; H1, H2, H3, and H5 to humans; H1 and H3 to swine; and H3 and H7 to horses).
- Usually the avian flu strains are highly virulent as they possess **PB1F2** protein, which targets host mitochondria and induces apoptosis.

Avian Flu Infection in Birds

- Bird flu strains are highly lethal to chickens and turkeys (but avirulent to ducks) and are the major cause of economic loss in poultry causing severe mortality in chickens.
- Unlike in mammals, avian flu multiplies in intestinal tracts of birds and shed through feces into water (avian flu is a water borne disease in birds).
- The influenza viruses do not undergo antigenic variation in birds, because of the short life span of birds.

Avian Flu Infection in Humans

It is believed that, to date, all human pandemic strains have originated by reassortment between avian and human influenza viruses and the mixing has occurred in pigs.
A/H5N1 is the most common avian flu strain that has been endemic in the world for the past 15 years.

- **Origin:** It was first reported from Hong Kong in 1997 and has spread to various countries including India within few years.
- **Transmission** to man occurs only from birds, and requires close respiratory contact.
- **Less morbidity:** As there is no human-human transmission, morbidity is less. Only 500 cases were reported between 1977 to 2010 from Asia and Middle East.
- **More mortality:** The avian flu strains are highly virulent (due to presence of PB1F2 protein) and mortality rate is >60%.
- **Clinical feature:** H5N1 avian flu strains are associated with higher rates of pneumonia (>50%) and extra pulmonary manifestations such as diarrhoea and CNS involvement.

Other avian flu strains that can cause human infections are:

- A/H7N7(Netherlands)
- A/H9N2 (Hong Kong)
- A/H7N9 (caused an outbreak in China, 2013)

Laboratory Diagnosis

Avian flu strains can be identified by real time reverse transcriptase PCR detecting specific HA and NA genes.

TREATMENT	Avian flu
Drug of choice is oseltamivir (Tamiflu)	

A/H1N1 2009 Flu

It has caused the most recent pandemic of influenza, emerged in California in March 2009 and rapidly spread to the entire world including India over the next few months. WHO declared the pandemics in 11th June 2009.

Epidemiology

- **Origin:** H1N1 2009 flu originated by genetic reassortment of four strains (1 human strain + 2 swine strains + 1 avian strain) and the mixing had occurred in pigs (Fig. 44.3).
- Though people commonly use the word 'swine flu' to describe H1N1 2009 flu, but this is not the correct terminology as it is a **reassortant of four strains.**
- **Transmission:** It can be transmitted from human to human, which has accounted for its rapid spread.
- However, it is less virulent (as it lacks the *PB1 F2* protein)
- Therefore in contrast to H5N1, the H1N1 2009 flu has caused more morbidity but less mortality.
- Currently, **World** is in the post pandemic period except in India and New Zealand where still local intense transmission is on-going.

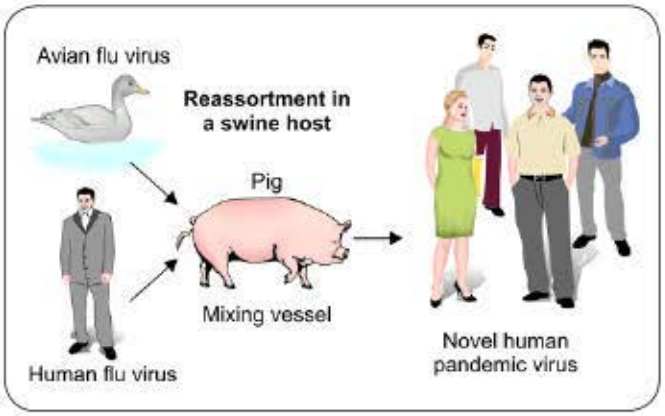


Fig. 44.3: Evolution of pandemic influenza virus

H1N1 in India

Since 2009 about 53,943 cases and 3,315 deaths due to H1N1 were reported from India, out of which in 2013 alone nearly 708 cases with 132 deaths have occurred.

However, a threatening outbreak of H1N1 started again in early 2015 affecting 33,761 people with 2035 deaths (up to March 30th 2015). The worst hit states are Rajasthan, Gujarat, Maharashtra and Madhya Pradesh.

Clinical Features

- **Uncomplicated influenza:** Most of the cases present with mild upper respiratory tract illness and diarrhoea.
- **Complicated/severe influenza** can occur very rarely in high risk groups, is characterized by features such as secondary bacterial pneumonia, dehydration, CNS involvement, and multi organ failure.

Lab Diagnosis

Real time reverse transcriptase PCR can detect and quantify the specific HA and NA genes.

TREATMENT	A/H1N1 2009 flu
▪ Drug of choice is neuraminidase inhibitors– • Oseltamivir (Tamiflu) tablet—75 mg twice a day for 5 days • Zanamivir (inhalational forms) ▪ H1N1 flu is resistant to amantadine	

Prevention

General preventive measures include

- Avoid contact with infected people
- Stay at home if you are sick
- Contain your coughs and sneezes-by using mask (special N95 mask for health care workers)
- Wash your hands thoroughly and frequently Vaccine

Vaccine: Both killed injectable and live nasal spray vaccines are available for A/H1N12009 flu.

PARAMYXOVIRIDAE

Paramyxoviridae contains of a group of viruses,which are transmitted via the respiratory route following which:

- They may cause localized respiratory infection in children (e.g. respiratory syncytial virus and the parainfluenza viruses) or;
- They may disseminate throughout the body to cause highly contagious diseases of childhood such as mumps (parotid enlargement) and measles (rashes).

Rubella virus is though not a paramyxovirus, because of its clinical and epidemiological resemblance to measles virus; it has been discussed in this chapter.

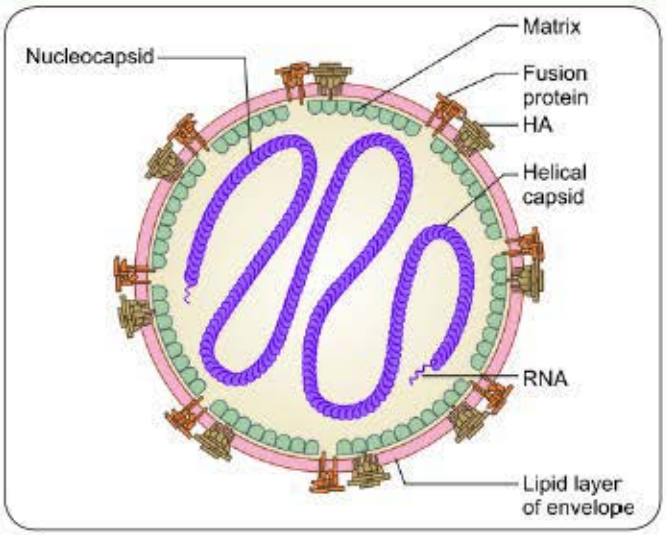

Fig. 44.4: Measles virus (schematic diagram)

MORPHOLOGY AND CLASSIFICATION

Paramyxoviruses resemble orthomyxoviruses in morphology, but are larger and more pleomorphic (Fig. 44.4).

- **Size:** Vary from 100–300 nm, rarely upto 800 nm. Long filaments and giant forms may be rarely seen rarely.
- Possess a **helical nucleocapsid** of 18 nm size.
- **RNA:** Contains a ss RNA which is linear, non-segmented and negative-sense.
- **Contains six structural proteins** which form capsid, polymerase, matrix protein (that underlies the viral envelope) and envelope glycoproteins.
- **Envelope:** The nucleocapsid is surrounded by a host derived lipid envelope in which the following virus-coded peplomers (glycoproteins) are inserted (see box below).

Glycoproteins of paramyxoviruses

- **F-glycoproteins** are present in all paramyxoviruses and mediate membrane fusion. They also have hemolysin activity (except in pneumoviruses).
- **Larger glycoproteins** help in attachment to the host cells. They may be either H or HN or G types.
  - HN glycoproteins have both hemagglutinin and neuraminidase activities e.g. in parainfluenza and mumps viruses.
  - H glycoproteins have only hemagglutinin activity- e.g. in measles
  - G glycoproteins do not have hemagglutinin and neuraminidase activities, but help in attachment- e.g. in respiratory syncytial virus.

Paramyxoviridae family is divided into two subfamilies and seven genera, out of which six contain human pathogens (Table 44.4).

PARAINFLUENZA VIRUSES

Human parainfluenza viruses are one of the major causes of lower respiratory tract disease in young children. It has five serotypes:

- Types 1 and 3 belong to the genus *Respirovirus*
- Types 2, 4 a and 4b belong to the genus *Rubulavirus*

Pathogenesis and Clinical Manifestations

- Transmission is by respiratory route (by direct salivary contact or by large-droplet aerosols)
- The incubation period appears to be 5–6 days.
- Virus multiplies locally and causes various respiratory manifestations such as:

TABLE 44.4 Characteristics of family Paramyxoviridae

Subfamilies	Paramyxovirinae				Pneumovirinae	
Genera	*Respirovirus*	*Rubulavirus*	*Morbillivirus*	*Henipavirus*	*Pneumovirus*	*Metapneumovirus*
Human viruses	Parainfluenza 1, 3	Mumps, Parainfluenza 2, 4a, 4b	Measles	Hendra, Nipah (Zoonotic)	Respiratory syncytial virus	Human metapneumovirus
Nucleocapsid	18 nm	18 nm	18 nm	*	13 nm	13 nm
Large Glycoproteins	HN type	HN type	H type	G type	G type	G type
Hemagglutinin	+	+	+	–	–	–
Neuraminidase	+	+	–	–	–	–
Fusion protein	+	+	+	+	+	+
Hemolysin	+	+	+	*	–	–
Inclusions	Cytoplasm	Cytoplasm	Cytoplasm and Nucleus	*	Cytoplasm	*

* Not yet identified

Abbreviations: HN, have both hemagglutinin and neuraminidase activities; H, have only hemagglutinin activity; G, do not have both hemagglutinin and neuraminidase activities.

- Mild common cold syndrome like rhinitis and pharyngitis are the most common presentation, seen with all serotypes.
- Croup (laryngotracheobronchitis):
  - Occurs in 2–3% of cases
  - Typically seen with type 1 and 2.
  - Involves children (between 6 to 18 months)
- Pneumonia or bronchiolitis:
  - Occurs very rarely
  - Seen especially with serotype 3
  - Involves infants below 6 months
- Otitis media is the most common complication of parainfluenza virus infection

- Reinfections are common, but less severe. There is no cross protection between the serotypes.
- Immunocompromised people are susceptible to severe infections. In older children and adults, disease is milder.

Epidemiology

Parainfluenza viruses are worldwide in distribution.

- Type 3 is the most prevalent serotype. It exists as endemic throughout the year with annual epidemics occur during spring.
- Types 1 and 2 infections are less common and seasonal, and tend to cause epidemics during the rainfall or winter, cyclically every alternate-year.
- Type 4a and 4b cause much milder illness and these serotypes are the most difficult to be isolated.
- Parainfluenza viruses are important cause of outbreaks in pediatric wards, day care centers and in schools.

Laboratory Diagnosis

- **Antigen detection:** Viral antigens in the infected exfoliated epithelial cells of the nasopharynx can be detected by direct-IF test by using specific monoclonal antibodies. It is rapid, but less sensitive than viral isolation.
- **Viral isolation:**
  - **Specimens** such as nasal washes, bronchoalveolar lavage fluid and lung tissue can be used. Specimen should be inoculated as early as possible to obtain best results.
  - **Primary monkey kidney cell line** is most sensitive and alternatively, a continous monkey kidney cell line-LLC-MK2 can be used.
  - They produce little or no cytopathic effect.
  - Viral growth can be detected by performing hemadsorption using guinea pig erythrocytes or antigen detection by direct-IF tests.
  - Shell vial technique is followed to enhance viral replication.
- **Serum antibodies** can be measured by neutralization test, hemagglutination inhibition test or ELISA. Presence of IgM or fourfold rise of IgG titer is indicative of active infection.
- **Reverse transcriptase PCR** assays are highly specific and sensitive but available only in limited settings.

Animal Parainfluenza Viruses

Certain animal parainfluenza viruses are related to the human strains.

- Sendai virus of mice is a subtype of human parainfluenza virus type 1.
- SV5, a common contaminant of primary monkey kidney cell lines, is related to parainfluenza virus type 2.
- Shipping fever virus of cattle and sheep (SF4) is a subtype of parainfluenza virus type 3.

Avian Parainfluenza Viruses (Newcastle Disease Virus or NDV)

NDV (also called Ranikhet virus in India) produces pneumoencephalitis in young chickens and mild flu like illness in older birds.

Human infection is rare and occupational; characterized by mild self-limiting conjunctivitis that may occur in workers handling infected birds.

MUMPS VIRUS

Mumps virus is the most common cause of parotid gland enlargement in children. In severe cases, it can also cause orchitis and aseptic meningitis.

Pathogenesis

- **Transmission** is through the respiratory route via droplets, saliva, and fomites.
- **Primary replication** occurs in the nasal mucosa or upper respiratory mucosa → infects mononuclear cells and regional lymph nodes → spills over to blood stream resulting in viremia → dissemination.
- **Target sites:** Mumps virus has a special affinity for glandular epithelium. The classic sites include the salivary glands, testes, pancreas, ovaries, mammary glands and central nervous system.

Clinical Manifestation

- **Incubation period** is about 19 days (range, 7–23 days).
- **Inapparent infection:** Up to half of the infected people are either asymptomatic or present with non-specific symptoms such as fever, myalgia and anorexia. This is more common in adults than in children.
- **Bilateral parotitis:** Acute non-suppurative parotid gland enlargement is the most common specific manifestation, present in 70–90% of the cases (Fig. 44.5).

Fig. 44.5: Parotitis in a mumps virus infected patient (arrow showing)

Source: Public Health Image Library, ID# 1861/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Rarely, parotitis may be unilateral
- In some cases, other salivary glands may also be involved.

- **Epididymo-orchitis** is the next most common manifestation of mumps, developing in 15-30% of cases in postpubertal males. Orchitis is unilateral in most of the cases, hence infertility following mumps orchitis is rare.
- **Aseptic meningitis** occurs in less than 10% of cases, with a male predominance. It is self-limiting condition except the deafness (due to cranial nerve palsy) which may be permanent.
- **Oophoritis** occurs in about 5% of women.
- **Pancreatitis** occurs in 4% of infections and may lead to diabetes.
- **Atypical mumps:** Parotitis may be absent in 10% of cases and patients are directly presented with aseptic meningitis.

Epidemiology

Mumps is endemic worldwide, sporadic cases occurring throughout the year, with a peak in cases typically in winter and spring. Epidemics occur every 3–5 years; typically associated with unvaccinated people living in overcrowded areas.

- **Period of communicability:** Patients are infectious from 1 week before to 1 week after the onset of symptoms.
  - Most contagious period is within 1–2 days before the onset of symptoms.
  - Infective material: Mumps virus is shed in saliva, respiratory droplets, and urine.
- **Source:** Cases (both clinical and subclinical cases) are the source of infection.
  - There is no carrier state.
  - Subclinical cases (30–40% of all cases) are responsible for maintaining the cycle of infection.
- **Reservoir:** Humans are the only reservoir of infection.
- **Incidence:** In most part of the world, the annual incidence of mumps is about 100-1,000 cases per 10,000 populations. However, cases are much reduced after the start of immunization, except for the 2006 outbreak of USA which had witnessed over 5700 cases.
- **Age:** Children of **5–9 years** age are most commonly affected; however, no age is exempt if there is no previous immunity. Disease tends to be more severe in adults.
- **Immunity:** One attack (either by vaccine or infection) gives lifelong immunity.
- Secondary attack rate is high (86%).

LABORATORY DIAGNOSIS	Mumps virus

- **Specimen:** Buccal or oral swab
- **Antigen detection** by direct IF test
- **Viral isolation**
  - Primary monkey kidney cell lines
  - Shell vial technique
- **Serum antibodies** by ELISA, neutralization test, hemagglutination inhibition test
- **RT PCR:** detects viral RNA

Laboratory Diagnosis

- **Specimens:** The buccal or oral swab specimens are the most ideal specimens, although mumps can also be detected in saliva, CSF, urine (shed up to two weeks), seminal fluid and rarely blood. Massaging the parotid gland area for 30 seconds prior to swabbing is recommended.
- **Direct viral antigen detection** can be done by using mumps-specific immunofluorescent staining (direct-IF) of clinical specimens
- **Virus isolation:** Monkey kidney cells are the preferred cell lines. Specimens should be inoculated immediately.
  - Viral growth after 1–2 weeks can be detected by demonstration of cytopathic effect (cell rounding and giant cell formation) or hemadsorption.
  - Shell vial technique is followed for rapid detection in 1–2 days.
- **Serum antibodies detection:** ELISA is the most widely used assay. Separate ELISA formats are available for detecting mumps specific IgM and IgG separately. Mumps ELISA is highly specific, does not cross-react with parainfluenza antibodies.
  - Detection of IgM antibodies (present up to 60 days of infection), or a rise in IgG titer indicates active infection.
  - The traditional tests such as neutralization test, hemagglutination inhibition test and complement fixation tests are seldom used now.

- **Reverse-transcription PCR** is available to detect mumps specific RNA. It is highly sensitive and specific.

TREATMENT — Mumps virus

- There is no specific antiviral drug available. Treatment is mostly symptomatic.
- Mumps immunoglobulin is available, but not effective, hence not recommended for treatment or post-exposure prophylaxis.

Prevention (Live Attenuated Vaccine)

- **Vaccine Strain:** Live attenuated Jeryl Lynn strain is the recommended strain used worldwide. Other strains available are RIT 4385, Urabe strain and L-Zagreb strain.
- Mumps vaccine is prepared in chick embryo cell line.
- **Mumps vaccine is available as**
  - Trivalent MMR vaccine (live attenuated measles-mumps-rubella vaccine) or
  - Quadrivalent MMR-V vaccine (contains additional live attenuated varicella vaccine).
  - Monovalent mumps vaccine (not commonly used)
- **Schedule:** Two doses of MMR is given by IM route at 1 year and 4–6 year (before starting of school).
- **Efficacy** is about 90% after the second dose. Neutralizing antibodies appear in 95% of the recipients. Duration of long term immunity is unknown.

MEASLES (RUBEOLA) VIRUS

Measles is an acute, highly contagious childhood disease, characterized by fever and respiratory symptoms, followed by typical maculopapular rash (Fig. 44.4).

Pathogenesis

- **Transmission** occurs predominantly via the respiratory route either by—
  - Droplets inhalation over short distances (common)
  - Small-particle aerosols that remain suspended especially in schools, hospitals, and enclosed public places in the air for longer period (less common).
- **Spread:** The virus multiplies locally in the respiratory tract; then spreads to the regional lymph nodes → enters into the bloodstream in infected monocytes (primary viremia) → further multiplies in reticuloendothelial system → spills over into blood (secondary viremia) → disseminates to various sites.
- **Target sites:** The virus is predominantly seeded in the epithelial surfaces of the body, including the skin, respiratory tract, and conjunctiva.

Clinical Manifestations

Incubation period is about 10 days which may be shorter in infants and longer (up to 3 weeks) in adults. Disease can be divided into three stages.

1. Prodromal Stage

This stage lasts for 4 days (i.e. from 10th to 14th day of infection) and is characterized by manifestations such as:

- **Fever** is the first manifestation, occurs on day 1 (i.e. on 10^{th} day of infection).
- **Koplik's spots** are pathognomonic of measles, appear after two days following fever (i.e. on 12^{th} day of infection) and are characterized by:
  - White to bluish spot (1mm size) surrounded by an erythema.
  - Appear first on buccal mucosa near second lower molars (Fig. 44.6A).
  - Rapidly spread to involve the entire buccal mucosa and then fade with the onset of rash.
- **Non-specific symptoms** may be present such as cough, coryza, nasal discharge, redness of eye, diarrhea or vomiting.

Figs 44.6A to C: **A.** Koplik spot in buccal mucosa (measles) (arrow showing); **B.** Measles rashes (on face); **C.** Multinucleated giant cell of measles infected cell lines (arrow showing)

Source: A. Public Health Image Library, ID# 6111, B. ID# 17980, C. ID# 859/Centers for Disease Control and Prevention (CDC), Atlanta *(with permission)*

2. Eruptive Stage

Maculopapular dusky red rashes appear after 4 days of fever (i.e. on 14th day of infection).

- Rashes typically appear first **behind the ears** → then spread to face, arm, trunk and legs → then fade in the same order after 4 days of onset (Fig. 44.6B).
- Rashes are typically absent in HIV infected people.

Fever (10th day) → Koplik's spot (12th day) → rash(14th day)

3. Post Measles Stage

It is characterized by weight loss and weakness. There may be failure to recover and gradual deterioration into chronic illness.

Complications

Secondary Bacterial Infections

Following measles, there is profound immune suppression and fall of cell mediated immunity which in turn predisposes to various secondary bacterial infections.

- Otitis media and bronchopneumonia are most common.
- Recurrence of fever or failure of fever to subside with the rash.
- Worsening of underlying tuberculosis with a false positive Mantoux test.

Complications Due to Measles Virus Itself

- Giant-cell pneumonitis (Hecht's pneumonia) in immunocompromised children, and HIV infected people.
- Acute laryngotracheobronchitis (croup).
- Diarrhoea, leads to malnutrition including vitamin A deficiency.

Central Nervous System Complications

CNS complications are rare, but most severe.

- **Post-measles encephalomyelitis:** It develops within 2 weeks of onset of rash. It represents an autoimmune response against the myelin basic protein. Its occurrence is about 1 in 1000 cases, affecting mainly older children and adults.
- **Measles inclusion body encephalitis** occurs months after rashes, typically affecting people with defective cell-mediated immunity (CMI).
- **Subacute sclerosing panencephalitis (SSPE):** It is a slowly progressive disease characterized by seizures and progressive deterioration of cognitive and motor functions.
  - SSPE belongs to group C slow virus infection, caused by a defective measles virus.
  - Occurrence is 1 in 300,000 measles cases
  - Age: SSPE typically develops if the primary measles virus infection occurs in children less than 2 years of age.
  - SSPE usually develops after 7–13 years after primary measles infection. It is fatal within 1–3 years of onset with mortality rate of 10-20%.
  - High titer antibody to measles virus in CSF is diagnostic.

LABORATORY DIAGNOSIS	Measles virus

- **Specimen:** Nasopharyngeal swab
- **Antigen detection:** By using anti-nucleoprotein antibodies.
- **Virus isolation:**
  - Monkey or human kidney cells or Vero/ hSLAM cell line-produces CPE as multinucleated giant cells (Warthin-Finkeldey cells).
  - Shell vial culture
- **Antibody detection:** Against nucleoprotein antigen by ELISA or neutralization tests.
- **Reverse-transcription PCR**-detects viral RNA.

Laboratory Diagnosis

Specimens

Nasopharyngeal swab, conjunctival swab, blood, respiratory secretions, and urine are the ideal specimens. Synthetic swabs are recommended.

Antigen Detection

Measles antigens in the infected cells can be detected directly by using anti-nucleoprotein antibodies.

Virus Isolation

- **Cell lines:** Monkey or human kidney cells or a lymphoblastoid cell line (B95-a) are optimal cell lines used for isolation of measles virus. Vero/hSLAM cell line is the CDC recommended cell line. This is a Vero cell line coated with measles specific hSLAM receptors (human signalling lymphocytic activation molecule).
- Cytopathic effect may be observed after 7–10 days of inoculation into cell lines characterized by-multinucleated giant cells (**Warthin-Finkeldey cells**) containing both intranuclear and intracytoplasmic inclusion bodies (Fig. 44.6C).
- Shell vial culture (centrifugation of culture followed by immunofluorescence detection of measles antigens in the inoculated cultures) is recommended for early detection in 2–3 days.

Antibody Detection

- Detection of measles-specific IgM antibody in serum or oral fluid or four fold rise of IgG antibody titer between acute and convalescent-phase sera is taken as significant.

- Demonstration of high titre measles antibody in the CSF is diagnostic of SSPE.
- ELISA is the most recommended test that uses recombinant measles nucleoprotein (NP) antigen. IgM antibodies are detected by capture ELISA whereas IgG antibodies are detected by indirect ELISA.
- In past, other tests such as neutralization test, hemagglutination inhibition test and complement fixation tests were used.
- Neutralization tests are sensitive and specific, and the results are highly correlated with protective immunity; however, require maintenance of virus in cell lines and thus are expensive and labour intensive.

Reverse-transcription PCR

RT-PCR specific for measles RNA detection is available.

- It is extremely sensitive and specific,
- It may also permit characterization of measles virus genotypes for molecular epidemiologic studies.
- It can distinguish wild-type from vaccine virus strains.
- RNA can be detected in specimens up to 10–14 days post rashes, in contrast to virus isolation, which often becomes negative after 3 days of rash.

Measles genotypes

There are 8 clades of measles which are further grouped into 23 recognized genotypes (WHO).
Globally, genotype B3 is the most common, where as in India, D8 is common.

TREATMENT **Measles virus**

- There is no specific antiviral therapy available for measles.
- Treatment is symptomatic and consists of general supportive measures.
- Vitamin A has been effective in reducing the morbidity and mortality due to measles.

Live Attenuated Measles Vaccine

- **Strains:** Most attenuated strains that are in use currently are derived from the original Edmonston strain isolated in 1954, which includes:
  - Schwartz strain (currently serves as the standard in much of the world).
  - Edmonston-Zagreb strain.
  - Moraten strain.
- Vaccine is prepared in chick embryo cell line.
- **Reconstitution:** Vaccine is available in lyophilized form and it has to be reconstituted with distilled water and then should be used within 4 hours.
- Vaccine is thermolabile, hence it must be stored at –20°C.
- One dose (0.5 mL) containing more than 1000 infective viral units is administered subcutaneously.
- **Indication:** Under national immunization schedule of India, measles vaccine is given at 9 months (because maternal antibody disappears by this time) along with vitamin-A supplements.
- However, it can be given at 6 months during measles outbreak, in that case a second dose should be given at 9 month.
- **Combined vaccines:** Measles vaccine is available in combined form with mumps and rubella vaccine (MMR vaccine) and with varicella (MMR-V vaccine).
- **Side effects include:**
  - Mild measles like illness may develop in 15–20% of vaccinees. There is no spread of the vaccine virus in the community.
  - Toxic shock syndrome (due to contamination of vial with *S. aureus* toxins).
- **Contacts:** Susceptible contacts over 9–12 months may be protected against measles if the measles vaccine is given within 3 days of exposure. This is because incubation period of measles induced by the vaccine strain is about 7 days, compared to 10 days for the naturally occurring measles.
  - Measles immunoglobulin (Ig) can also be given within 3 days, at a WHO recommended dose of 0.25 mg/kg of body weight.
  - However, both vaccine and Ig should not be given together. At least 8–12 weeks of gap must be maintained.

Epidemiology

Measles is endemic throughout the world with epidemics which recur regularly every 2–3 years, typically in late winter and early spring.

- **Source:** Cases are the only source of infection. Carriers are not known to occur. In-apparent or sub-clinical infections are rare.
- **Reservoir:** Humans are the only reservoir of infection. There is no animal reservoir.
- **Infective material:** Virus is shed in the secretions of nose, throat and respiratory tract of cases of measles, especially during the prodromal stage and early stage of rash.
- **Period of communicability:** Patients are infectious from four days before to four days after the onset of rash. Patients are highly contagious, isolation is recommended from the onset of prodromal stage until third day of rash.
- **Secondary attack rate** is very high (> 90%).
- **Age:** Measles is a childhood disease
  - Children (6 months to 3 years) are the most susceptible group in developing countries.

- Older children (> 5 years) are commonly affected in developed countries or in vaccinated population.

- **Immunity:** No age is immune if there is no previous immunity.
  - There is single serotype hence one attack (vaccine or infection) gives lifelong immunity.
  - Infants are protected up to 6 months due to pre-existing maternal antibodies.
- **Epidemic** of measles occurs if proportion of susceptible children exceeds 40%.Though disease burden has much decreased after the vaccine was made available, measles is still a leading cause of death of young children in many developing countries.
- **Worldwide,** an estimated 20 million people get measles and 122,000 people die from the disease each year-that equals about 330 deaths every day or about 14 deaths every hour.
- **Outbreaks in 2014** had occurred in Philippines and Vietnam affecting more than 50,000 and 10,000 suspected cases respectively.

Measles eradication

Measles is amenable to eradication. With the efficient and widespread immunization programme, it is possible to eradicate measles from the world.

WHO measles elimination strategy: "Catch up, Keep up and Follow up" the immunization programme.

- **Catch-up campaign** is a one-time effort to vaccinate all children between 9 months up to 10 years irrespective of their prior immunization status .The aim is to rapidly reduce the susceptible population in the community.
- **Follow-up campaigns** are done every 2–4 years following catch-up campaigns to vaccinate all children of > 9 months age who have born after the last catch-up campaign.
- **Keep up** the on going national immunization programme.

NIPAH VIRUS AND HENDRA VIRUS

They are zoonotic paramyxoviruses. Hendra virus was first isolated in 1994 in Hendra (Australia) and Nipah virus was discovered in 1999 in Malaysia.

- **Reservoir:** Fruit bats (flying foxes) are the natural host for both Nipah and Hendra viruses.
- **Geographical distribution:** Hendra virus infections are confined to horses in Australia, whereas Nipah viruses cause infection of pigs in Malaysia.
- **Transmission:**
  - Hendra virus is transmitted by exposure to infected body fluids and excretions of horses.
  - Nipah virus is transmitted by close contact with infected pigs.
- **Clinical manifestations:** Both the viruses are rare causes of encephalitis in humans.
- **Risk factors:** Ecologic changes, including land use and animal husbandry practices, are probably the reasons for the emergence of infection.
- Both viruses are of public health concerns because of their high mortality, wide host range, and ability to jump species barriers.
- They are also prone to cause laboratory acquired infections and are classified as biosafety level 4 pathogens.

RESPIRATORY SYNCYTIAL VIRUS

Respiratory syncytial virus (RSV) is a major respiratory pathogen of young children and is the most common cause of lower respiratory disease (bronchiolitis and pneumonia) in infants.

Pathogenesis

- **Transmission:** RSV is spread by (i) direct contact (contaminated fingers or fomites and by self-inoculation onto the conjunctiva or anterior nares or (ii) by large droplets inhalation.
- **Spread:** RSV replicates locally in the epithelial cells of the nasopharynx and may spread to the lower respiratory tract to cause bronchiolitis and pneumonia.
- **Pathology:** Lymphocytes in large numbers migrate to the site of infection and secrete several cytokines which cause the following changes:
  - Peribronchiolar infiltration of inflammatory cells.
  - Submucosal edema
  - Necrosis of the bronchiolar epithelium and
  - Formation of plugs consisting of mucus, cellular debris, and fibrin which occlude the smaller bronchioles.

Clinical Manifestations

RSV causes a wide spectrum of respiratory illnesses

- **Incubation period** is about 3–5 days.
- **Infants:** RSV is the most common cause of lower respiratory tract infection below 1 year of age, causing bronchiolitis, pneumonia, and tracheobronchitis in 25–40% of infected infants.
- **Symptoms:** It begins with running nose, fever and accompanied by cough, wheezing and dyspnea.
  - Chest X-ray shows peri-bronchial thickening, diffuse interstitial infiltration and occasionally lobar consolidation.
  - Infection is severe in premature infants and underlying congenital cardiac disease, bronchopulmonary dysplasia, nephrotic syndrome, or immunosuppression.
- **Adults:** RSV produces influenza-like upper respiratory symptoms such as common cold, running nose, sore throat, and cough. Infections are common in overcrowded communities (military recruits).
  - Lower respiratory tract infections can occasionally occur among transplant recipients or immunocompromised adults or elderly nursing-home residents

  - RSV can cause exacerbation and worsening of asthma or COPD (chronic obstructive lung disease).
- **Recurrent infection** is common in both children and adults, but is much milder (common cold).

Laboratory Diagnosis

Antigen Detection

Direct identification of viral antigens in clinical samples is rapid and sensitive. Two methods are commonly used; both use monoclonal antibodies specific for RSV.

- Direct immunofluorescence test detecting antigens on exfoliated cells or
- ELISA detecting antigens in nasopharyngeal secretions.

Virus Isolation

HeLa and HEp-2 are the most sensitive cell lines for RSV isolation. As RSV is extremely labile, freezing should be avoided and specimens should be processed immediately.

- A characteristic cytopathic effect, **syncytium formation** (multinucleated giant cell)-appears after 10 days. Hence it is named as syncytial virus.
- **Shell vial technique** is done to enhance the viral replication, which helps in early growth detection within 1–2 days.
- Sensitivities of virus isolation or antigen detection are excellent in children (80–95%), but low in adults.

Reverse Transcriptase-PCR

RT-PCR amplifying viral RNA has shown higher sensitivity and specificity, particularly in adults.

Antibody Detection

Various formats such as Immunofluorescence, ELISA, and neutralization tests are available for antibody detection.

- Antibodies are often found in older children and adults but may not be elevated in children <4 months of age.
- Serum antibodies are of less diagnostic importance; rather they are the markers of prevalence of infection (epidemiological significance).

Epidemiology

Infection with RSV occurs worldwide.

- **Seasonality:** Annual epidemics tend to occur following rainfall, in winter and spring and last up to 5 months. Infection is not seen in summer.
- **Age:** RSV is a leading respiratory pathogen in children. Infants between ages of 6 weeks to 6 months of age are commonly affected, with peak incidence at 2 months.
- **Prevalence:** About 70% of infants are infected by 1 year of age and almost all by 2 years of age.
- **Subgroups:** RSV can be typed into two subgroups; Subgroup A infections appear to cause more severe illness than subgroup B.

TREATMENT **Respiratory syncytial virus**

Unlike other respiratory viruses, specific antiviral drug is available for the treatment of RSV.

- **Ribavirin** is the drug of choice.
  - It is indicated for severe infections in infants. However its beneficial effect to older children and adult is doubtful.
  - It is administered as aerosols for 3–6 days. Oral ribavirin is not recommended.
- Supportive care is also needed such as removal of secretions, administration of oxygen, bronchodilators and ventilatory support.
- Immunoglobulin with high titers of antibody to RSV was used in the past, but was found ineffective and hence it is not recommended currently.

HUMAN METAPNEUMOVIRUS

Human metapneumovirus was first reported in 2001, though the avian strains were prevalent since 1970s.

- They cause both upper and lower respiratory tract illnesses similar to those caused by RSV but less severe and tend to affect slightly older children.
- It may be the second most common cause (next to RSV) of lower respiratory infection in young children.
- They also cause respiratory disease in adults with underlying hematologic malignancies.
- **Diagnosis:** RT-PCR is available to amplify the RNA extracted from respiratory specimens. Specific antigens in nasopharyngeal secretions can be detected by direct-IF test.

RUBELLA

Rubella is not a myxovirus, but it has been discussed in this chapter because it produces a childhood exanthema similar to that of measles (hence rubella is also known as **German measles**). However, unlike measles, it is highly teratogenic; can cause congenital rubella syndrome.

MORPHOLOGY

Rubella belongs to Togaviridae family, and is the only member under genus *Rubivirus*.

- It is enveloped, single-stranded RNA virus measuring 50–70 nm in size.
- Its envelope contains a lipid layer from which two types of spike-like glycoproteins (E1 and E2) are projected.
- There is only one serotype and humans are its only known reservoir.

TYPES OF RUBELLA INFECTIONS

Rubella may present as postnatal infection or congenital infection.

Postnatal Rubella

Postnatal rubella may occur during neonatal age, childhood, and adult life.

Transmission

Rubella virus spreads from person to person by respiratory droplets via upper respiratory mucosa.

Spread

Rubella virus replicates locally in the nasopharynx, and then spreads to the lymph nodes. Subsequently, viremia develops after 7–9 days, and lasts until 14th day by which time both antibody and rashes appear almost simultaneously suggesting an immunologic basis for the appearance of rash.

Clinical Manifestations

- Incubation period is about 14 days (range, 12–23 days).
- Subclinical infection may be seen in 20–50% of cases.
- Rashes are often the first manifestations in children, but in older children and adults, 1 to 5-day prodrome often precedes the rash which includes low-grade fever, malaise, and upper respiratory symptoms.
- **Rashes** are generalized and maculopapular in nature, start on the face, extend to trunk and extremities, and disappear in 3 days (Fig. 44.7A).
- **Lymphadenopathy** (occipital and postauricular) is the most striking feature.
- **Forchheimer spots** may be seen in some cases. They are pin-head sized petechiae; develop on the soft palate and uvula; usually start with the onset of rash.

Complications

Arthralgia and arthritis are common in adults, particularly in women. Thrombocytopenia and encephalitis are rarely encountered.

Figs 44.7A and B: A. Child with rubella rash; **B.** Cataract seen in congenital rubella infection (arrows showing)

LABORATORY DIAGNOSIS — Rubella virus

- **Specimen:** Nasopharyngeal or throat swabs
- **Virus Isolation:**
  - In monkey or rabbit origin cell lines and then growth detected by viral interference
  - Shell vial technique
- **Antibody detection:** By HAI or ELISA

Laboratory Diagnosis

Isolation of Virus

- **Ideal specimen:** Nasopharyngeal or throat swabs taken 6 days before and after onset of rash.
- **Ideal cell line:** Monkey or rabbit origin cell lines may be used.
- Rubella is a non-cytopathic virus. Traditionally, it can be identified by demonstrating viral interference property by co-infecting the cell line with cytopathic echovirus
- It can also be identified more rapidly in cell line by shell vial technique.

Serology (Antibody Detection)

Hemagglutination inhibition test (HAI) is most widely used standard antibody detection test for rubella infection. However, it cannot differentiate recent and past infection and serum needs to be pretreated to remove nonspecific inhibitors before testing.

ELISA is the preferred method of rubella diagnosis in modern days because serum pre-treatment is not required and it detects both IgM and IgG separately.

- IgM appears on 15th day of infection and lasts for 2-3 weeks.
- IgG appears late and persists for life and indicates past infection or post vaccination.
- Reinfections may occur rarely and should be diagnosed by a fourfold rise of IgG.

Congenital Rubella Syndrome

The most serious consequence of rubella virus infection is Congenital Rubella Syndrome. Rubella is highly teratogenic and is included in the list of the agents causing congenital infection known as 'TORCH complex [***T**oxoplasma*, **O**thers (e.g. varicella, agent of syphilis), **R**ubella virus, **C**ytomegalovirus and **H**erpes simplex virus].

Transmission

- Both the risk of transmission to fetus and severity of congenital infection are maximum if the mother acquires the virus during first trimester of pregnancy.
- Risk after 5th month of pregnancy is almost negligible (90% risk at 11 weeks vs 20% risk at 20 weeks of gestation).

Clinical Manifestations

Permanent Congenital Defects

- **Classical triad consists of:**
  - **Ear defect:** Sensory neural deafness (most common defect of congenital rubella syndrome).
  - **Ocular defects:** Salt-and-pepper retinopathy is the most common ocular defect followed by cataract (Fig. 44.7B).
  - **Cardiac defect:** Patent ductus arteriosus (PDA) is the most common cardiac defect followed by pulmonary artery stenosis and ventricular septal defect.
- **CNS defects** such as—microcephaly, mental retardation, motor delay and autism.

Transient Congenital Changes

The transient changes such as hepatosplenomegaly, bone lesion, intrauterine growth retardation (IUGR) and thrombocytopenia with petechiae (**Blueberry muffin syndrome**) may be seen.

Outcome in the fetus may be miscarriage, fetal death, or premature birth with congenital defects.

Laboratory Diagnosis

- IgM antibodies do not cross placenta; their presence in a neonate is diagnostic of congenital rubella infection.
- IgG antibodies cannot differentiate between maternal transfer and a true congenital infection. However, IgG antibodies persisting in baby's serum beyond the expected time of disappearance of maternal IgG can also be used as a criterion to diagnose congenital rubella infection.
- Isolation of virus can be done especially from the throat swab, to lesser extent from urine (excreted up to 1 year). and CSF. It is more likely to be positive in the first six months after the birth.
- Reverse transcriptase PCR to detect viral RNA.

EPIDEMIOLOGY

- **Source:** The cases are the only source of infection. There is no known carrier state.
- **Duration of protection:** Once infected, the person acquires lifelong immunity
- **In India,** still 40% females of reproductive age group are susceptible to rubella infection.
- **Period of communicability** of rubella is about 1 week before to 1 week after the appearance of rash.
- **Transmission** occurs via—respiratory droplet, transplacental and rarely via contact, and sexual modes.
- **Occurrence:** Rubella occurs worldwide and throughout the year with a peak in the spring. Epidemics occur every 6–8 years, with explosive pandemics every 20–25 years.
- **The largest recent rubella epidemic** (post natal) occurred globally in 1962–1965. However; with the onset of vaccine use, the epidemics are less encountered now a days.
- **Congenital rubella** remains an important public health problem globally.

TREATMENT **Rubella**

Rubella is a mild, self-limited illness and no specific treatment is available.

VACCINATION

RA 27/3 is a live attenuated vaccine for rubella, prepared from human diploid fibroblast cell line.

- It is available singly or in combination with vaccines of mumps and measles (MMR vaccine).
- **Schedule:** Single dose (0.5 mL) of vaccine is administered subcutaneously.
- Following vaccination, seroconversion occurs in 90% of recipients and immunity persists for 14–16 years or probably lifelong.
- **Indication:** In India, rubella vaccine is indicated in all women of reproductive age (first priority group) followed by all children (1–14 years).
- **Precautions:**
  - Vaccine is contraindicated in pregnancy.
  - As it is teratogenic, pregnancy should be avoided at least for 4 weeks (28 days) following vaccination.
  - Infants below 1 year should not be vaccinated due to possible interference from persisting maternal antibody.

EXPECTED QUESTIONS

I. Essay:

1. In early 2015, a 62-year-old debilitated man from Rajasthan presented with symptoms of severe upper respiratory tract infection. He had a history of exposure to a patient having similar condition. Throat swab collected was sent to the reference laboratory for real time PCR which revealed that causative agent could be a segmented RNA virus.
   a. What is the most probable etiological diagnosis and the mechanism of emergence of this particular strain of the virus?
   b. Describe the pathogenesis, mode of transmission and laboratory diagnosis of the causative agent?
   c. Add a note on the epidemiological impact of the recent 2015 epidemic in India produced by the causative agent.
   d. What are the preventive measures available for this condition?
2. Describe the pathogenesis and laboratory diagnosis of measles virus infection.

II. Write short notes on:

a. Mumps
b. H1N1 2009 pandemic flu
c. Avian flu
d. Congenital rubella syndrome

III. Multiple Choice Questions (MCQs):

1. The type-specific antigen (A, B, or C) of influenza viruses is found on which viral constituent?
   a. Hemagglutinin
   b. Neuraminidase
   c. Nucleocapsid
   d. Lipid in the viral envelope

2. Which of the following statements concerning antigenic drift in influenza viruses is correct?
   a. It results in major antigenic changes
   b. It is exhibited only by influenza A viruses
   c. It is due to frame-shift mutations in viral genes
   d. It occurs frequently than antigenic shift

3. Which of the following statements about congenital rubella syndrome is correct?
   a. Following vaccination, seroconversion occurs in 40% of recipients
   b. Congenital abnormalities occur when a nonimmune pregnant woman is infected at any time during pregnancy
   c. Deafness is a common defect associated with congenital rubella syndrome
   d. Only rare strains of rubella virus are teratogenic

4. Which of the following paramyxoviruses has a surface glycoprotein lacking hemagglutinin activity?
   a. Measles virus
   b. Mumps virus
   c. Parainfluenza virus type 1
   d. Respiratory syncytial virus

CHAPTER 45

Picornaviruses

Chapter Preview

- Classification
- Morphology
- Enteroviruses
  - Poliovirus
  - Coxsackievirus
  - Echovirus
  - Parechovirus
  - Enteroviruses 68–72
- Rhinoviruses

CLASSIFICATION

Picronaviruses belong to the family Picornaviridae; which include two major groups of human pathogens: enteroviruses and rhinoviruses.

Enteroviruses: They are transmitted by feco-oral route.

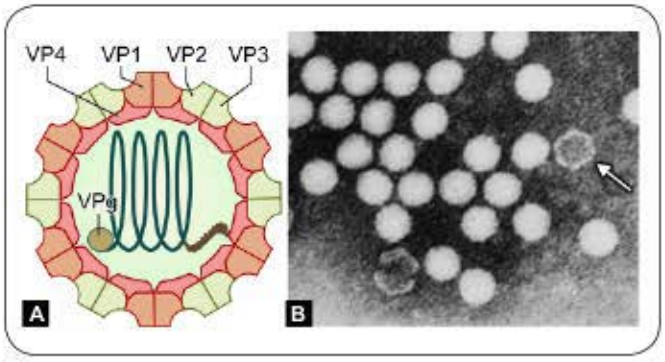
- Though they multiply in the intestine, they do not cause any intestinal manifestations.
- They are associated with various systemic manifestations including *poliomyelitis* (a childhood flaccid paralysis), which is in the verge of eradication globally.
- Enteroviruses comprise of 96 human serotypes:
  - Poliovirus (3 serotypes)
  - Coxsackievirus—Coxsackie A (1–24 serotypes), Coxsackie B (1–6 serotypes)
  - Echovirus (1–33 serotypes)
  - Parechovirus (1–3 serotypes)
  - Enteroviruses 68–72 (serotype 72 is reclassified as Hepatitis A virus).
  - 34 newly identified enteroviruses (beginning with enterovirus 73).

Rhinoviruses: They are transmitted by respiratory route and cause common cold.

MORPHOLOGY

Picornaviruses are simple in structure, very small (28–30 nm size) and nonenveloped.

- They are spherical shaped and have icosahedral symmetry (Figs 45.1A and B).
- Capsid is composed of 60 subunits, each consisting of four viral proteins (VP1-VP4), except parechoviruses (have three proteins).
- Possess single-stranded positive sense linear RNA.
- **Resistance:**
  - Enteroviruses are stable at acidic pH, whereas rhinoviruses are acid-labile.



Figs 45.1A and B: Poliovirus. **A.** Schematic diagram; **B.** Transmission electron micrograph (arrow showing)

Source: B. Public Health Image Library, ID#235/Dr. Joseph J. Esposito, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

  - Heat labile: All enteroviruses and some rhinoviruses are inactivated by heating at 55°C for 30 minutes, which can be prevented by magnesium chloride.

ENTEROVIRUS GROUP

POLIOVIRUSES

Antigenic Types

There are three antigenic types of polioviruses. Immunity (antibody response) is type-specific.

1. **Type-1** (Brunhilde and Mahoney strains): It is the most common serotype to cause epidemics of poliomyelitis. This serotype is responsible for all the natural cases of poliomyelitis occurring gobally at present.
2. **Type-2** (Lansing and MEF-1 strain): It is the most antigenic serotype and hence is the easiest serotype to be eradicated.

- No natural case of poliomyelitis caused by serotype 2 has been reported since 1999.
- However, the vaccine strains can cause poliomyelitis and it is the most common serotype found among the VDPV strains (vaccine derived poliovirus).

3. **Type-3** (Leon and Saukett strain)
   - No natural case caused by serotype-3 has been reported since 2013.
   - However, the vaccine strains have the potential to cause paralytic poliomyelitis.
   - It is considered as the most common serotype to cause VAPP (vaccine-associated paralytic poliomyelitis).

Poliovirus has two antigens: C and D

- The *D antigen* (dense): It is associated with the whole virion and is type-specific. Anti-D antibodies are protective and therefore the potency of the injectable polio vaccine can be measured in terms of D antigen units.
- The *C antigen* (capsid): It is associated with the noninfectious virus and is less specific. Anti-C antibody does not neutralize virus infectivity.

Pathogenesis

- **Transmission:** Polioviruses are transmitted by feco-oral route (most common), followed by respiratory droplets via inhalation or rarely by conjunctival contact.
- **Multiply locally:** It multiples in intestinal epithelial cells, sub mucosal lymphoid tissues, tonsils and Peyer's patches.
- **Receptor:** Viral entry into the host cells is mediated by binding to *CD155* receptors present on the host cell surface.
- **Spread to CNS/spinal cord:**
  - **Hematogenous spread** (most common): Virus spreads to the regional lymph nodes and spills over to the bloodstream (primary viremia). After further multiplying in the reticuloendothelial system, the virus enters the bloodstream again, causing secondary viremia. Then it is carried to the spinal cord and brain.
  - **Neural spread:** Virus may also spread directly through nerves. This occurs especially following tonsillectomy where the virus may spread via glossopharyngeal nerve present in the tonsillar fossa.
- **Site of action:** The final target site for poliovirus is the motor nerve ending i.e. anterior horn cells of the spinal cord which leads to muscle weakness and flaccid paralysis.
- **Neuron degeneration:** Virus-infected neurons undergo degeneration. Earliest change in neuron is the degeneration of **Nissl body** (aggregated ribosomes, normally found in the cytoplasm of neurons).
- Pathological changes are always more extensive than the distribution of paralysis.

Clinical Manifestations

The incubation period is usually 7–14 days. The manifestations may range from asymptomatic stage to the most severe paralytic stage.

- **Inapparent infection:** Following infection, the majority (91–96%) of cases are asymptomatic.
- **Abortive infection:** About 5% of patients develop minor symptoms such as fever, malaise, sore throat, anorexia, myalgia, and headache.
- **Nonparalytic poliomyelitis:** It is seen in 1% of patients, presented as aseptic meningitis.
- **Paralytic poliomyelitis** is the least common form (< 1%) among all the stages:
  - It is characterized by descending asymmetric acute flaccid paralysis (AFP).
  - Proximal muscles are affected earlier than the distal muscles; paralysis starts at hip → proceeds towards extremities; which leads to the characteristic tripod sign (child sits with flexed hip, both arms are extended towards the back for support) (Fig. 45.2).
  - **Sites involved** can be spinal, bulbospinal and bulbar. Accordingly, the nature of paralysis varies (e.g. respiratory insufficiency or dysphagia are common in bulbar involvement).
  - **Biphasic course:** In children, the disease progression is typically biphasic; aseptic meningitis occurs first → recovery → return of fever with paralytic features 1–2 days later.

Figs 45.2A and B: Deformities in poliomyelitis

Source: Public Health Image Library, A. ID# /13211, B. ID#5578, Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Cranial nerves are also involved occasionally.
- However, there is no sensory loss.

- **Risk factors:** Paralytic disease is more common among:
  - Older children and adults.
  - Pregnant women.
  - Following heavy muscular exercise.
  - Persons undergoing trauma at the time of CNS symptoms.
  - Tonsillectomy: It predisposes to bulbar poliomyelitis.
  - IM injections: They increase the risk of paralysis in the involved limb.
- **Postpolio muscle atrophy syndrome:** A recrudescence of paralysis and muscle wasting has been observed in individuals, usually decades (20–40 years) after the episode of paralytic poliomyelitis.

LABORATORY DIAGNOSIS — **Polioviruses**

- Virus isolation in primary monkey kidney cell line from throat swabs, rectal swabs or stool samples—viral growth is detected by CPE, viral antigen or viral gene in cell line.
- Antibody detection—by neutralization test and CFT

Laboratory Diagnosis

Virus Isolation

- **Specimen:** Poliovirus may be recovered from the throat swabs (up to 1 week of illness) and from rectal swabs or stool samples (up to 6–8 weeks). However, long-term excretion has been observed in immunodeficient persons. Virus isolation from CSF or blood is very rare.
- **Transport:** Specimens should be kept frozen during transport to the laboratory.
- **Cell line:** Primary monkey kidney cells are the most recommended cell lines. Virus growth can be identified by various methods.
  - Cytopathogenic effects appear in 3–6 days; described as crenation and degeneration of the entire cell sheet.
  - Antigen detection: Isolated virus can be identified and serotyped by neutralization with specific antiserum.
  - Specific gene detection by polymerase chain reaction (PCR) assays.

Antibody Detection

Rising antibody titer in paired sera collected 1–2 weeks interval is recommended.

- Both neutralizing antibodies (neutralization test) and complement fixing antibodies (complement fixation test) can be detected.
- Only first infection with poliovirus produces strictly type-specific responses.
- Subsequent infections induce antibodies against group-specific antigen common to all the three serotypes.

Vaccine

Both inactivated and live attenuated polio vaccines are available; both have their own unique useful properties as well as drawbacks (Table 45.1).

Injectable Polio Vaccine (IPV, Salk Vaccine)

- **Discovery:** Jonas Salk had prepared IPV in HeLa cells in 1952. It was announced to the world by Dr Thomas Francis in 1955.
- **Cutter incident** (named after the manufacturer): An outbreak of vaccine induced paralytic poliomyelitis had occurred in America (1955) that had killed more than 100 people. It was due to improper inactivation of IPV. Vaccine was modified later, after which it has been completely safe.
- **Preparation:** Virus is grown in **monkey kidney cell line** and inactivated by formalin. Each dose (0.5 ml) of vaccine contains total 80 units of D-antigen of all the three poliovirus serotypes (40 units of type 1, 8 units of type 2, and 32 units of type 3).
- **Schedule:** It is administered by intramuscular route in four doses—1st three doses with 1–2 months gap, 4th booster dose is given 6–12 months after the 3rd dose.
- **Efficacy** of 80–90% is achieved after the full course of vaccination.
- **Advantages:**
  - IPV is much safer than oral polio vaccine (OPV), safer even in immunocompromized people.
  - It does not cause vaccine-associated paralytic polio (VAPP).
  - It is more stable, does not require stringent storage conditions.
- **Disadvantages:**
  - It does not provide herd immunity: Being inactivated vaccine, it cannot spread by feco-oral route.
  - It does not useful during epidemics; as there is no community protectiont. Instead, it can precipitate paralysis.
  - It does not induce mucosal IgA production, hence the local immunity is absent.
  - It is relatively expensive than OPV.

Oral Polio Vaccine (OPV, Sabin Vaccine)

- **Discovery:** OPV was developed by Albert Sabin, Koprowski and Cox who prepared OPV independently almost around the same time (1955).
- **Preparation:** Each dose (0.5 mL) contains type 1 virus (3 lakh), type 2 virus (1 lakh), type 3 virus (3 lakh) of TCID50 (tissue culture infective dose-50).
- **Markers of attenuation:**
  - **Phenotypic markers** were used in the past to confirm attenuation. Vaccine virus will not grow in presence of low levels of bicarbonate, at 40°C, or in

TABLE 45.1: Differences between injectable and oral polio vaccines

Polio vaccine	Salk (injectable)	Sabin (oral)
Preparation	Formalin killed preparation in MKC (Monkey kidney cell line) **Total 80 units of D-antigen of:** ▪ Type 1 (40 units) ▪ Type 2 (8 units) ▪ Type 3 (32 units)	**Each dose contains TCID50 of:** Type 1: 3 lakh, Type 2: 1 lakh, Type 3: 3 lakh, **Markers of attenuation :Vaccine virus :** ▪ **Phenotypic markers:** Vaccine virus will not grow in presence of low levels bicarbonate, at 40°C, or in MKC and is inactivated by specific antisera ▪ **Genotypic markers:** Detects specific genes of attenuated virus
Dose	Four doses: 1st three doses—at 1–2 months gap, 4th booster—after 6–12 months gap	Total five doses: Zero dose—given at birth 1st/2nd /3rd—at 6/10/14weeks of age, Booster: 16–24 months
Safety	Relatively safer than OPV	Safe except in immunocompromised patients, pregnancy, old age
Efficacy	80–90% by full course of IPV Immune response is slower than OPV	90–100% efficacy is achieved even by 1 or 2 doses of OPV Efficacy decreases by: ▪ Interference by other enteroviruses ▪ Diarrheal diseases ▪ Breastfeeding
Economy	Relatively expensive	Economical
Duration of protection	Short, need booster doses periodically	Long-lasting
In epidemics	Can precipitate paralysis	Can be used safely
Herd immunity	Not provided	Provided due to feco-oral spread of vaccine virus
Local immunity	Weakly stimulated	Strongly stimulated (due to IgA antibody)
Can prevent	Only paralysis	Paralysis and intestinal re-infection
Storage condition	Relatively stable Doesn't require stringent condition	Should be stored at (–20°C) Stabilized in $MgCl_2$, pH<7
VAPP and VDPV	Zero chance	Relatively more chance

Abbreviations: OPV, oral polio vaccine; IPV, injectable polio vaccine; VAPP, vaccine-associated poliomyelitis; VDPV, vaccine-derived polioviruses, MKC- monkey kidney cell lines

monkey kidney cell lines and it should be inactivated by specific antisera (McBride's marker).
- **Genotypic markers:** Currently, attenuation is confirmed by detecting specific genes of attenuated virus, which are absent in wild virus.

- **Schedule:** OPV is the vaccine recommended under national immunization schedule of India. It is administered orally (two drops/dose). Total five doses are given.
  - Zero dose: Given at birth
  - 1st/2nd/3rd doses: Given at 6/10/14 weeks
  - Booster dose: Given at 16–24 months of birth
- **Efficacy** is about 90–100%, which is achieved much faster (with one or two doses than IPV).
- **Advantages:**
  - **Herd immunity:** OPV strains being live, can shed in the feces and spread in the community by feco-oral route, hence it can induce herd immunity. It can provide both individual and community protection.
  - OPV is the vaccine of choice during epidemics.
  - **Local immunity:** OPV induces mucosal IgA production, hence provides local or mucosal immunity.
  - Cheaper than IPV
  - Easy to administer (given by oral route).
- **Disadvantages:**
  - **Safety:** OPV is otherwise safe, but it is risky to give in immunocompromised people, pregnancy, and old age.
  - **Stability:** OPV is unstable vaccine, requires stringent conditions such as:
    - Storage at (–20°C),
    - Stabilized in $MgCl_2$,
    - Maintenance of pH <7
  - **Efficacy of OPV decreases by:**
    - **Interference** by other enteroviruses
    - **Diarrhea:** OPV gets washed away in diarrheal stool. However, OPV can be given during diarrhea for community protection, but such a dose should not be counted. After recovery from diarrhea, again a repeat dose should be given.
    - **Breastfeeding:** OPV gets washed away in stool if given immediately before or after breast feeding. Hence, breast feeding should be avoided before or after administration of OPV.
  - OPV can cause vaccine-associated paralytic poliomyelitis (VAPP) and vaccine-derived polioviruses (VDPV) (described below).

VAPP and VDPV

Vaccine-associated Paralytic Poliomyelitis (VAPP)

VAPP denotes all the cases of paralytic poliomyelitis that occur following OPV administration.

- VAPP strains are **OPV-like isolates**, which show limited genetic divergence from their parental OPV strains (<1% divergence).
- VAPP cases are ubiquitous in places where OPV is used extensively.
- VAPP can occur among OPV recipients as well as to their close contacts due to feco-oral spread.
- However, VAPP strains are not capable of circulating in the community and do not cause outbreaks. This is largely because the spread of OPV-related virus is largely limited by high population immunity.
- **VAPP rate:** VAPP occurs approximately at a rate of one case per 2.5 million doses of OPV.
- **VAPP occurs more frequently**
  - Following the first dose of OPV than the subsequent doses.
  - Among people with primary immunodeficiency disorder (↑ risk by 3000 fold).
- **Most common serotype** associated with VAPP is Sabin type 3 (60%) followed by Sabin type 2.

Vaccine-derived polioviruses (VDPVs)

VDPV isolates exhibit a higher level of genetic divergence from their parental OPV strains at VP1 sequence, which helps in their prolonged replication, and transmission.

- The genetic divergence of VDPVs from parental OPV strains is about:
  - More than 1% for Sabin types 1 and 3.
  - More than 0.6% for Sabin type 2.
- Isolates showing genetic divergence lower than this cutoff are considered as **OPV-like isolates**.
- VDPV isolates are indistinguishable from wild polioviruses both clinically (due to regain of neurovirulence) and phenotypically (due to reversal of markers of attenuation).
- Most VDPV isolates belong to Sabin type 2 (90%) followed by type 1. This is because wild type-2 strains are already eradicated and not circulating in the community since 1999.

VDPVs can be categorized into three types:

1. **Circulating VDPVs (cVDPVs):** These strains are capable of person-to-person transmission in the community and can cause outbreaks in areas with low OPV coverage.
   - They pose the same threat to the community as that of wild polioviruses.
   - Most cVDPV isolates have vaccine/non-vaccine recombinant genomes, i.e. genetic recombination occurs between vaccine strains and other enteroviruses that facilitates person to person transmission.
   - Since 2000, cVDPV outbreaks have occurred in 18 countries, with majority (87.1%) of reported cases are associated with **type 2.**
   - In 2013, over 700 strains of VDPVs have been isolated worldwide including India. Nigeria was worst affected, accounting for half of those strains.
2. **Immunodeficiency-associated VDPVs (iVDPVs):** They are isolated from persons with primary immunodeficiency disorder.
   - Such patients do not develop disease, but excrete the iVDPVs for many years.
   - Contacts infected with iVDPV strains are at ↑ risk of developing paralytic poliomyelitis.
   - iVDPVs exhibit greater genetic diversity than cVDPVs-some strains may be diverse by > 10%.
   - The extent of sequence divergence is proportional to the duration of the infection.
   - Unlike cVDPV, infections due to iVDPV cannot be prevented by high OPV coverage.
   - iVDPV strains show heterogeneity within a serotype; leading to mixed virus populations.
3. **Ambiguous VDPVs (aVDPVs):** They are heterogeneous; They are either cVDPVs for which only 1 case isolate had yet been detected, or they may be sewage isolates obtained from developed countries with unknown source (probably iVDPV).

Epidemiology

- **Reservoir:** Man is the only known reservoir. Most cases are subclinical.
- **Clinical-subclinical ratio:** For every clinical case, there may be 1,000 children and 75 adults of subclinical cases.
- There are **no chronic carriers**. However, immunodeficient individuals may excrete the virus for longer periods.
- **Source:** Infective materials such as stool and oropharyngeal secretions are the sources of infection.
- **Age:** Younger children and infants are more susceptible to infection than adults. However in developed countries, there is shift of age; affecting older children.
- **Period of communicability:** Patients are infectious, shedding the virus in the feces from 7–10 days before the onset of symptoms up to 2–3 weeks thereafter, sometimes as long as 3–4 months.

Polio Eradication

Poliomyelitis is now at the verge of eradication. This is attributed to the extensive immunization programme being conducted globally.

Pulse Polio Immunization (PPI) was initiated globally to eradicate poliomyelitis. In India, it was in operation since 1995-96.

- Two rounds of PPI (6 weeks apart) are scheduled every year during the winter season, where all children under the age of five years are vaccinated with OPV irrespective of their OPV vaccination status.

- PPI doses of OPV are considered as extra doses and they do not replace the OPV doses received under the routine national immunization schedule.
- AFP Surveillance: Acute flaccid paralysis surveillance has been conducted to identify all remaining infected areas and to monitor progress towards eradication.

Polio Situation in the World

- **Endemic (PAN) countries:** Currently polio is endemic only in three countries—Pakistan, Afghanistan and Nigeria (abbreviated as PAN countries).
- **Emergency Action Plans** in 2012 have been initiated to boost polio vaccination coverage to levels necessary to stop transmission.
- **Wild poliovirus (wPV) cases:**
  - In 2015, only 27 cases are reported gobally (up to June 2015).
  - In 2014, 359 cases were reported worldwide, Pakistan accounted for the maximum cases (306 cases). However, 19 cases (out of 359) were reported from non-endemic countries such as Somalia, Guinea, Iraq and Cameroon.
- Currently, all natural cases due to wPV are caused by type-1. No natural cases due to Type-2 and 3 have been reported since 1999 and 2013 respectively.
- **India** has been declared polio-free since January 2014, the last natural case was detected three years back (2011).
- **The Global Polio Eradication Initiative (GPEI)** had launched 'Eradication and Endgame Strategic Plan' (2013–2018) aiming to wipeout polio from the entire world by 2018 (see the box below).

Endgame Strategic Plan (2013–2018)

GPEI had initiated an end game strategic plan for polio eradication, which has four objectives.

1. **Interruption of poliovirus transmission**
2. **Strengthening immunization systems** by step wise withdrawal of OPV along with switching over to IPV.
   - Introduction of one dose of IPV by the end of 2015: Third dose of OPV will be withdrawn and replaced by IPV.
   - Withdrawal of Serotype-2: Trivalent OPV will be replaced by Bivalent OPV (serotype 1 and 3) six months after starting IPV (i.e. mid-2016).
   - IPV only: Complete withdrawal of OPV and replacement with only IPV in immunization schedule by 2019.
3. **Implementing containment of polioviruses** and to certify the world as polio-free by end of 2018.
4. **Legacy planning:** The infrastructure, fund, man-power, knowledge and experience that have been created through the global polio eradication programme will be utilized to support other health programmes following postpolio eradication.

COXSACKIEVIRUSES

Coxsackieviruses (named after the place of discovery; Coxsackie village in USA) can be divided into two groups, A and B, based on their pathogenic potentials for suckling mice.

Serotypes: Group A coxsackieviruses are typed into serotypes 1–24 (there is no serotype 23) and group B are typed into serotypes 1–6.

Clinical Manifestations

Coxsackieviruses produce a variety of clinical illnesses in humans associated with different serotypes. The incubation period ranges from 2 to 9 days.

- **Aseptic meningitis:** It is caused by all types of group B coxsackieviruses and by many group-A coxsackieviruses (most commonly A7 and A9).
- **Herpangina:** It is a severe febrile vesicular pharyngitis that is caused by certain group A viruses (type 2–6, 8, 10).
- **Hand-foot-and-mouth disease:** It is characterized by oral and pharyngeal ulcerations and vesicular rashes of the palms and soles which heal without crusting. It is particularly associated with coxsackievirus A16.
- **Pleurodynia** (also known as **Bornholm disease** or epidemic myalgia): It is caused by coxsackie B viruses. It is characterized by fever and abrupt onset of stabbing chest pain.
- **Cardiac:** Myocarditis and pericarditis are caused by coxsackievirus B types 1–5.
- **Respiratory:** Coxsackieviruses A and B have been associated with common colds. Pneumonia may be caused by coxsackieviruses B4 and 5.
- **Acute hemorrhagic conjunctivitis:** It is caused by coxsackie-A24 and enterovirus 70.
  - It is a self-limiting subconjunctival hemorrhage. Incubation period is about 1 day. Complete recovery occurs within 8–10 days.
  - It had caused explosive epidemics among adults, during 1969–71 in Africa and Southeast Asia.
- **Generalized disease of infants:** It is an extremely serious disease involving multiple organs, caused by group B coxsackieviruses.
- **Pancreatitis** leading to juvenile diabetes mellitus is caused by coxsackie B4.

The differences between group A and B coxsackieviruses are given in Table 45.2.

Laboratory Diagnosis

- **Specimen collection** depends on the type of infection. Important specimens include throat swabs, stool and CSF.
- **Isolation of the virus:** Coxsackieviruses can be recovered by:

TABLE 45.2: Differences between group-A and group-B Coxsackieviruses

Group A coxsackieviruses	Group B coxsackieviruses
Suckling mouse intracerebral inoculation	
▪ Flaccid paralysis ▪ Generalized myositis	▪ Spastic paralysis in mice ▪ Focal myositis and necrosis of brown fat
Manifestations	
▪ Aseptic meningitis (A7,A9) ▪ Herpangina (vesicular pharyngitis) ▪ Hand-foot-and-mouth disease (also by enterovirus: 71) ▪ Acute hemorrhagic conjunctivitis: Caused by coxsackie virus-A24 and enterovirus 70	More organ involvement seen ▪ Aseptic meningitis (B1–6) ▪ Pleurodynia (epidemic myalgia or Bornholm disease) ▪ Myocarditis, pericarditis ▪ Hepatitis ▪ Pancreatitis leading to Juvenile diabetes mellitus: Coxsackie B4 ▪ Pneumonia ▪ Generalized disease of infants
Host cell receptor	
Intercellular adhesion molecule 1 (ICAM-1) is a receptor for Coxsackieviruses A13, A18, and A21	CAR (Coxsackievirus and adenovirus receptor) is the receptor for: ▪ All group B coxsackieviruses ▪ Group C adenoviruses

  - Intracerebral inoculation into suckling mice-
    - Coxsackie-A produce flaccid paralysis
    - Coxsackie-B produce spastic paralysis
  - **Inoculating into tissue culture:** Cytopathic effect can be observed within 5–14 days.
- **PCR** is more useful as it is rapid, more sensitive and serotype-specific.
- **Serology** is performed to detect neutralizing antibodies.

OTHER ENTEROVIRUSES

Enteroviruses 68–71

- Enterovirus 68—causes pneumonia.
- Enterovirus 70—causes **acute hemorrhagic conjunctivitis**. It uses CD55 as host cell receptor.
- Enterovirus 71—causes aseptic meningitis, encephalitis, hand-foot-and-mouth disease, herpangina, pulmonary edema and paralysis resembling poliomyelitis.
- Enterovirus 72 is reclassified as hepatitis A virus.

Echoviruses

Echoviruses (enteric cytopathogenic human orphan viruses) infect the human intestine and they can be isolated in certain tissue cultures. They were named 'orphan' viruses because at the time of their discovery, they were not attributed to any disease.

- Echoviruses are further typed into serotypes 1–33 (there are no types—10, 22, 23 or 28), but not all cause human illness.
- They are associated with aseptic meningitis, encephalitis, rashes, common cold, and ocular disease.
- They can cause outbreaks in summer especially among children.
- Association with the disease is confirmed if the virus is isolated from body fluids (such as CSF) and antibodies are found in patient's sera.

Parechoviruses

Parechoviruses have three serotypes:

- Serotype 1 and 2 were previously classified as echoviruses 22 and 23 respectively.
- Their capsid consists of three viral proteins (in contrast to four proteins in most picornaviruses).
- They have been rarely associated with aseptic meningitis, respiratory and neonatal diseases.

RHINOVIRUS GROUP

Rhinoviruses are the most common cause of common cold.

- They use host cell intercellular adhesion molecule-1 (ICAM-1) as receptor.
- More than 100 serotypes have been identified.
- They are similar to enteroviruses in structure and properties except that:
  - Buoyant density in cesium chloride is of 1.40 g/mL (in contrast to 1.34 for enteroviruses).
  - Acid-labile (unstable below pH 6).
  - Transmission is by close respiratory contact via infected secretions.
  - Optimal temperature for growth is 33°C (in contrast to 37°C for enteroviruses).
- **Clinical features:**
  - The incubation period is about 2–4 days.
  - **Common cold syndrome:** Rhinoviral symptoms are similar to that of any other viruses causing common cold syndrome such as coronaviruses, adenoviruses, enteroviruses, parainfluenza viruses, and influenza viruses.
  - Usual symptoms in adults include sneezing, nasal obstruction, nasal discharge, and sore throat, but no fever.
  - Secondary bacterial infection may produce otitis media, sinusitis, bronchitis, or pneumonitis, especially in children.
- Relapse: The average adult gets 1–2 attacks each year.
- Rhinoviruses are infectious only for humans, gibbons, and chimpanzees.
- **Laboratory diagnosis:** Rhinoviruses can be grown in human diploid cell lines such as WI-38 and MRC-5 cell lines. Organ cultures of ferret and human tracheal epithelium may be necessary for some fastidious strains. Most of the strains grow better at 33°C (nasopharynx temperature) but not at 37°C.
- **Treatment** is supportive (i.e. symptomatic treatment).

EXPECTED QUESTIONS

I. Essay:

1. A 9-week-old baby named Sweety presented to the emergency room with weakness in her right leg. On examination, her right leg appeared flaccid and no deep tendon reflex or Babinski can be elicited, although sensation was intact. The tone, movement, sensation, and reflexes of her other limbs were normal. Her immunization records were up-to-date according to the national immunization schedule of India. CSF demonstrates elevated protein with normal glucose levels. Fecal sample was collected and then sent to the referral centre where the poliovirus is identified as a vaccine strain (not the "wild-type" strain) of poliovirus type-1 was isolated.
   a. What is the probable clinical diagnosis of this condition?
   b. Add a note on the laboratory diagnosis for confirming this condition.
   c. Mention the advantages and disadvantages of the vaccines available against the etiological agent.

II. Write short notes on:

a. Polio vaccine
b. Polio eradication
c. Coxsackievirus

III. Multiple Choice Questions (MCQs):

1. Zero dose of OPV is given:
   a. At one month
   b. At birth
   c. When child is having diarrhea
   d. When child is having polio

2. Enterovirus 72 is:
   a. Hepatitis A virus
   b. Hepatitis E virus
   c. Hepatitis B virus
   d. Hepatitis C virus

3. Not true about salk vaccine:
   a. Expensive than OPV
   b. Not useful in epidemics
   c. Contraindicated in low immunity
   d. Booster doses are required

4. The most common viruses that can cause meningo-encephalitis in children are:
   a. Arboviruses
   b. Herpesviruses
   c. Japanese encephalitis virus
   d. Enteroviruses

Answers

1. b **2.** a **3.** c **4.** d

CHAPTER 46

Arboviruses

Chapter Preview

- Introduction and classification
- Togaviridae
  - Fever-arthritis group—chikungunya virus and others
  - Encephalitis group
- Flaviviridae
  - Encephalitis viruses—Japanese B encephalitis virus and others
  - Hemorrhagic group—dengue virus, yellow fever virus and others
  - Tick transmitted flaviviruses—Kyasanur Forest disease virus and others
- Bunyaviridae
- Reoviridae
- Rhabdoviridae

INTRODUCTION

Definition

Arboviruses (arthropod-borne viruses) are diverse group of RNA viruses that are transmitted by blood sucking arthropods (insect vectors) from one vertebrate host to another.

Viruses must multiply inside the insects and establish a lifelong harmless infection in them. Thus, the viruses that are just mechanically transmitted by insects are not included in this group.

Taxonomically Incorrect But Worldwide Accepted Group

The members of arboviruses have diverse physical and chemical properties. Taxonomically also, they belong to different families.

Still, the name 'arbovirus' is internationally accepted as the members under this group are comparable in many ecological and epidemiological factors—such as geographical distribution, mode of transmission (type of insect vector), clinical features and their control measures.

Classification

Members of arboviruses belong to five different families: Togaviridae, Flaviviridae, Bunyaviridae, Reoviridae and Rhabdoviridae.

Individual viruses under each family are named after various features such as:

- **Clinical features:** For example yellow fever is named after its main clinical feature—jaundice.
- **Place of discovery:** For example Kyasanur Forest disease virus.
- **Vector needed for transmission:** For example sandfly fever virus.
- **Peak season:** For example Russian spring-summer encephalitis virus.
- **Multiple features:** Japanese encephalitis virus is named after the place of discovery and clinical feature.

Clinical Manifestations

Arboviruses may also be arbitrarily divided based on the pattern of clinical syndromes they produce.

- Fever and/or rash, and/or arthralgia group
- Encephalitis group
- Hemorrhagic fever group

However, some of them may be associated with more than one clinical syndromes e.g., dengue virus.

Epidemiology

- **Zoonotic:** Several hundred arboviruses exist in the world and all are believed to be endemic in animals. However, only about 100 are human pathogens.
- **Transmission cycle:** Arboviruses are maintained in the nature between animals and their insect vectors.
- **Humans are the accidental hosts** and do not play any role in the maintenance or transmission cycle of the virus, except for urban yellow fever and dengue.
- **Arthropod vector:** Most arboviruses are transmitted by mosquitoes (*Aedes*, *Culex* or *Anopheles*) followed by ticks, and rarely sandfly and other insects (Table 46.1).
- **Climatic variation:** Arboviruses are more prevalent in the tropics than temperate climate, due to abundance of appropriate animals and arthropods in the former.
- **Geographical distribution:** Arboviruses vary greatly in their geographical distribution which in turn depends on the various factors such as climatic condition and

TABLE 46.1: General features of arbovirus

Virus	Manifestation	Distribution	Vector	Reservoir
Family: Togaviridae				
Chikungunya virus	Fever and arthritis	Asia, Africa	*Aedes aegypti*	Monkeys *
O'Nyong-nyong virus	Fever and arthritis	Africa	*Anopheles*	*
Mayaro virus	Fever and arthritis	South America	*Aedes aegypti*	Monkeys
Ross River virus	Epidemic polyarthritis	Australia	*Aedes*	Small animals
Sindbis virus	Arthralgia, and rash	Africa, Europe, Australia	*Culex*	Birds, mammals
Semliki Forest virus	Fever and arthralgia	Africa	*Aedes*	Birds, rodents
Eastern equine encephalitis virus	Encephalitis	Eastern part of North America	*Aedes, Culex*	Birds
Western equine encephalitis virus	Encephalitis	Western part of North America	*Culex tarsalis, Aedes*	Birds
Venezuelan equine encephalitis virus	Encephalitis	South and central America	*Aedes, Culex*	Horses
Family: Flaviviridae				
Japanese B encephalitis virus	Encephalitis	South East Asia	*Culex tritaeniorhynchus*	Pigs, Birds
St. Louis encephalitis virus	Encephalitis	United States	*Culex*	Wild birds
West Nile encephalitis virus	Encephalitis	East Africa (Uganda), Algeria, Romania	*Culex, Aedes, Anopheles*	Birds
Murray Valley encephalitis virus	Encephalitis	America	*Culex annulirostris*	Birds
Rocio virus	Encephalitis	São Paulo, Brazil	*Culex*	*
Russian spring-summer encephalitis virus	Encephalitis	Central Europe, Russia	Tick	Rodents, other mammals, birds
Powassan virus	Encephalitis	America	Tick	Rodents
Louping-ill virus	Encephalitis	Europe	Tick	Sheep
Dengue virus	Hemorrhagic fever	India	*Aedes aegypti*	*
Yellow fever virus	Hemorrhagic fever	West Africa, Central South America	*Aedes aegypti*	Monkeys
Kyasanur Forest disease virus	Hemorrhagic fever	India (Karnataka)	Tick	Monkeys and rats
Omsk hemorrhagic fever virus	Hemorrhagic fever	Russia	Tick	Small mammals
Family: Bunyaviridae				
California encephalitis virus	Encephalitis	USA	*Aedes triseriatus*	Rodents
Oropouche virus	Rash and aseptic meningitis	Central and South America	*Culicoides paraensis*	Not known
Sandfly fever virus	fever and myalgia	Southern Europe, North Africa, India	Sandfly	Small mammals
Rift Valley fever virus	fever and myalgia	Africa	*Aedes*	Sheep, cattle
Crimean Congo hemorrhagic fever virus	Hemorrhagic fever	Africa	Tick	Small mammals
Ganjam virus	*	India	Tick	Small mammals
Family: Reoviridae				
Colorado tick fever virus	Fever, rarely encephalitis	America (mountains)	Tick	Rodents
Orungo virus	Fever	Sub-Saharan Africa	*Aedes*	*
Kemerovo virus	Fever, meningism	Russia	Tick	*
Family: Rhabdoviridae				
Vesicular stomatitis virus	Oral mucosal vesicles	Indiana	Sandfly	*
Chandipura virus	Encephalitis	India	Sandfly	*

* Not yet identified

presence of vector. Viruses that are highly endemic in one place, may not be found in other areas (Table 46.1).

- Yellow fever is highly endemic in West Africa, but not found at all in India in spite of its vector *Aedes aegypti* being widely distributed in India.
- **Encephalitic arboviruses:** Eastern, Western and Venezuelan equine encephalitis viruses are prevalent in North America where as in India, Japanese encephalitis virus is the most common arbovirus causing encephalitis.

- **Arboviruses found in India:** Over 40 arboviruses have been detected in India, of which three are highly endemic and produce several outbreaks every year.
  - **Common:** Dengue, chikungunya, and Japanese B encephalitis viruses are highly endemic in India.
  - **Rare:** Kyasanur Forest disease, West Nile, Sindbis, Crimean Congo hemorrhagic fever, Ganjam, Vellore, Chandipura, Bhanja, Umbre, Sathuperi, Chittoor, Minnal, Venkatapuram, Dhori, Kaisodi and sandfly fever viruses are among the rare arboviruses found in India.

LABORATORY DIAGNOSIS — Arboviral infections

- **Antibody detection:**
  - Older methods: Hemagglutination inhibition test (HAI), complement fixation test (CFT), and neutralization test
  - Newer methods (most widely used assays): ELISA (IgM and IgG specific) and ICT
- **Virus Isolation:**
  - Mosquito inoculation (adult or larval stage of *Toxorhynchites*)
  - Mosquito cell lines, such as C6/36 and AP61
  - Mammalian cell lines (such as vero cell line)
  - Suckling mice (intracerebral inoculation)
- **Detection of antigen:**
  - In blood, e.g. flavivirus specific NS1 antigen by ELISA and ICT
  - In fixed tissues by immunohistochemistry or direct-IF
- **Molecular methods:** RT-PCR and Real time RT-PCR

Laboratory Diagnosis of Arboviral Infection

Antibody Detection

The following tests can be performed to detect the antibodies in patient's serum against different arboviral infections

- **Older methods** (seldom used now):
  - Hemagglutination inhibition test.
  - Complement fixation test.
  - Neutralization test.
- **Newer methods** (most widely used assays):
  - ELISA (IgM and IgG specific).
  - Immunochromatographic test (ICT) based on lateral flow assay: This test can also differentiate IgM and IgG separately.
- **Indicators of active infection include**:
  - IgM detection.
  - Seroconversion of IgG.
  - Four fold rise in titer of IgG in paired sera (collected with 2–3 weeks gap between acute and convalescent phases).
- **Advantages:**
  - Because of their low cost and simplicity to perform, they are the most widely used tool at present for arboviral diagnosis.
  - They are also the best methods used for epidemiological surveillance.
- **Disadvantages:**
  - Antibody detection assays are often non-specific as broad group-reactive antigens are used (e.g. *Flavivirus*).
  - Most of the assays are IgG based; hence cannot differentiate between recent and past infection unless four-fold rise in paired sera is demonstrated.

Virus Isolation

Arboviruses can be isolated from the clinical specimens (blood, cerebrospinal fluid (CSF) or tissue homogenates) by the following methods

- **Adult or larval mosquito inoculation:** This is probably the most sensitive culture technique. Several mosquitoes are used such as *Toxorhynchites* (best), *Aedes aegypti* and *Aedes albopictus* (adult male mosquitoes).
- **Mosquito cell lines**, such as C6/36 and AP61 cell line are used which are moderately sensitive to arboviruses.
- **Mammalian cell lines** such as Vero and LLC-MK2 cell lines) inoculation is least sensitive.
- **Suckling mice (intracerebral inoculation):** It is also least sensitive.

Detection of Viral Growth

Viral antigens can be detected in mosquito head squashes, infected cells, infected cell-culture fluids, or mouse-brain touch preparations by direct immunofluorescence methods using:

- Group-specific (i.e. Flavivirus or togavirus specific) monoclonal antibodies or.
- Serotype-specific (e.g. specific for dengue virus serotypes) monoclonal antibodies.

Detection of Antigen

- **Antigen detection in blood:** Flavivirus specific **NS1 antigen** (non-structural antigen-1) can be detected in blood for the diagnosis of dengue. Both enzyme linked immunosorbant assay (ELISA) and immunochromatography (ICT) formats are available.
- **Antigen detection in fixed tissues:** Group-specific antigens (e.g. Flavivirus antigens) can be detected in peripheral blood leukocytes, liver, lung at autopsy, and less often in the lymph nodes, spleen, bone marrow, etc.
  - **Formats:** Immunohistochemistry, direct immunofluorescence and avidin–biotin enzyme assays have been standardized.
  - However, these tests are not widely available.

Molecular Methods

- **Reverse transcriptase PCR** has been developed to amplify the RNA present in the clinical specimens, specific for various arboviruses.

- **Real time reverse transcriptase PCR** has an added advantage of quantifying the viral load in the blood, hence can be used to monitor the disease progression.
- **Advantages:** Molecular methods have revolutionized the diagnosis of arboviruses.
  - They are highly sensitive, specific and rapid.
  - They can also be serotype-specific (e.g. four dengue serotypes can be detected).
- **Disadvantages**
  - False-positive results: Molecular assays are prone for contamination. Hence, assays should be performed meticulously.
  - Because of the cost factor, these assays are not widely used.

TREATMENT **Arboviral infections**

Treatment is by supportive measures, no specific antiviral drugs are available.

TOGAVIRIDAE

Classification: Family Togaviridae contains two genera

1. *Genus Alphavirus:* Contains about 30 different mosquito transmitted viruses out of which about 13 are human pathogens.
2. *Genus Rubivirus:* Contains rubella virus, which is not arthropod transmitted and is not an arbovirus. Because of its clinical overlapping with measles, it is discussed detail in Chapter 44.

Morphology: Togaviruses have the following properties:

- Spherical, 50–70 nm in diameter
- Nucleocapsid
  - Capsid contains 42 capsomeres.
  - **Genome:** Positive-sense, ssRNA
- **Enveloped virus:** Capsid is surrounded by a lipid envelope that contains two glycoproteins having hemagglutinating activity.
- **Replication:** They replicate in the cytoplasm and release by budding through host cell membranes.
- All togaviruses are **serologically related** to each other.
- Based on clinical manifestations, the pathogenic members of the genus *Alphavirus* can be categorized in to fever-arthritis group and encephalitic groups.

ALPHAVIRUS (FEVER-ARTHRITIS GROUP)

Chikungunya

Chikungunya fever is a re-emerging disease characterized by acute fever with severe arthralgia.

History

The name is derived from the *Makonde* word "kungunyala" meaning "that which bends up or gets folded" in reference to the stooped posture which develops as a result of the severe joint pain that occurs during the course of illness.

Transmission

- **Human Transmission occurs by:**
  - *Aedes* mosquito, primarily *Aedes aegypti* which bites during day time,
  - Rarely, by vertical transmission from mother to fetus or by blood transfusion
- **Transmission cycle:** Chikungunya virus is maintained in the environment through both urban and sylvan transmission cycle.
  - **Urban cycle:** Human beings serve as reservoir during epidemic periods and the transmission occurs between humans and *Aedes aegypti* mosquito.
  - **Sylvatic cycle:** It occurs in African forests, where the virus is maintained between the wild primates e.g. monkeys (which serve as reservoir) and forest species of *Aedes* (such as *A. furcifer, A. taylori* (which serve as vector).

Clinical Manifestations

- Incubation period is about 5 days (3–7 days).
- Most common symptoms are fever and severe joint pain (due to arthritis).
- **Arthritis** is polyarticular, migratory and edematous (joint swelling), predominantly affecting the small joints of wrists and ankles.
- Other symptoms include headache, muscle pain, tenosynovitis or skin rashes.
- Symptoms are often confusing with that of dengue. In general, chikungunya is less severe, less acute and hemorrhages are rare compared to dengue (Table 46.2).
- Most patients recover within a week, except for the joint pain (lasts for months).

TABLE 46.2: Manifestations of chikungunya and dengue

Features	Chikungunya	Dengue
Fever	Common	Common
Polyarthritis	Common	None
Tenosynovitis	Common	None
Rashes appear on	Day 1–4	Day 3–7
Myalgia	Possible	Common
Leukopenia	None	Common
Thrombocytopenia	None	Common
Retro-orbital pain	Rare	Common
Hypotension	Possible	Common
Minor bleeding	Rare	Common

- **High risk group:** This group includes newborns, older adults (≥65 years), and persons with underlying hypertension, diabetes, or heart disease.

Epidemiology

Chikungunya virus was first reported in Africa (Tanzania, 1952), was subsequently introduced into Asia and had caused several outbreaks in various African and Southeast Asian countries (Bangkok and India).

- **India (past):** Several outbreaks were reported during 1963–1973; e.g. Kolkata in 1963 and South India in 1964 (Pondicherry, Chennai-Vellore region) and Barsi in Maharashtra in 1973.
- Since then, it was **clinically quiescent** and no outbreaks were reported between 1973–2005 from most parts of the world, except for the few sporadic cases, which occurred in various places in the world including India (Maharashtra).
- **Re-emergence** (Reunion Outbreak): In 2005, Chikungunya re-emerged in Reunion Island of Indian Ocean and affected 2,58,000 people (almost one-third of country's population).

Reasons for Re-emergence

Re-emergence in 2005 was believed to be due to a novel mutation in the virus and a change in vector.

- **New mutation (E1-A226V):** Chikungunya virus underwent an important mutation. Alanine in the 226 position of E1 glycoprotein gene is replaced by valine.
- **New vector** (*Aedes albopictus*): This mutation led to a shift of vector preference. Mutated virus was found to be 100 times more infective to *A.albopictus* than to *A.aegypti*.

- **Spread:** Following the re-emergence, it has been associated with several outbreaks in India, other Southeast Asian and African countries and has also spread to some areas of America and Europe.
- The most recent epidemic had occurred in Colombia during 2014-15; which witnessed 82,977 clinically confirmed cases by end of 2014.
- **India (at present):** Chikungunya is endemic in several states.
  - **States:** Karnataka, Tamil Nadu, Andhra Pradesh and West Bengal have reported higher number of cases.
  - In 2014, nearly 14,452 cases were reported, much less than the previous years (95,091 cases in 2008).
  - Karnataka accounted for the maximum number of cases in the year 2013 and 2014.

Genotypes

Chikungunya virus has three genotypes—(1) West African, (2) East African and (3) Asian genotypes.

- Most Indian cases before 1973 were due to Asian genotypes.
- However, Reunion outbreak was caused due to a mutated strain which was closely related to an African genotype from Kenya and is responsible for most of the current outbreaks in India as well as in other parts of the world.

Laboratory Diagnosis

Laboratory diagnosis of chikungunya is similar to that of other arboviruses as described before.

- **Viral isolation** (in mosquito cell lines) and real time **RT- PCR** are best for early diagnosis (0–7 days).
- **Serum antibody detection:**
  - IgM appears after 4 days of infection and lasts for 3 months; IgG appears late (after 2 weeks) and lasts for years. So, detection of IgM or a fourfold rise in IgG titer is more significant.
  - **MAC ELISA** is the best format available showing excellent sensitivity and specificity with only little cross reactivity with other alphaviruses and dengue.
  - In India, ELISA kits are supplied by National Institute of Virology (NIV), Pune and National Institute of Communicable Diseases (NICD), Delhi.
  - Several other rapid dipstick tests are also available.
- **Biological markers** like IL-1β and IL-6 are increased and RANTES (Regulated on activation, normal T cell expressed and secreted) levels are decreased in chikungunya virus infection.

Vaccine

Recently, few vaccine trials are ongoing for chikungunya. In one of these trial, a live measles vaccine virus (Schwarz strain) is used as a vector; into the genome of which five structural genes from chikungunya virus have been incorporated.

O'Nyong-nyong (ONN) Virus

ONN virus is closely related to Chikungunya virus both clinically (rashes and arthritis) and antigenically. However, it is transmitted by the *Anopheles* species and infection is confined to Africa.

Mayaro Virus

It also causes a chikungunya like illness and is endemic in tropical South America. *Aedes aegypti* may be involved in human transmission in an urban setting.

Ross River Virus

It has been associated with **epidemic polyarthritis** in Australia and New Guinea.

- It is transmitted by several *Aedes* species such as *Aedes vigilax, A.polynesiensis* and *A.aegypti*.
- Focal cases were reported in India (Pune, 2010).

Sindbis Virus

Sindbis fever is a chikungunya like illness characterized by arthralgia, and rash.

- It is transmitted by *Culex* mosquito, first isolated from Egypt.
- **Geographical distribution:** It has been reported from the rural areas of Africa, Europe and Australia.
- Sindbis fever is called by different names in northern Europe (Pogosta disease in Finland, Karelian fever in Soviet Union, and Ockelbo disease in Sweden).
- In India, though the virus has been isolated, it is not associated with human disease.

Semliki Forest Virus

It was first isolated from *Aedes* mosquitoes in the Semliki Forest, Uganda (1942), and since then it is confined to Africa.

- It can cause lethal encephalitis in rodents. Its pathogenicity to humans is doubtful, rarely produces symptoms such as headache, fever, myalgia and arthralgia. It is transmitted by several mosquitoes.
- Because of its broad host range and efficient replication, it has also been used as a vector for genes encoding various vaccines and anti-cancer agents and as a tool for gene therapy.

ALPHAVIRUS (ENCEPHALITIS GROUP)

Eastern, Western and Venezuelan Equine Encephalitis Viruses

These viruses cause encephalitis in horses and humans.

- Eastern equine encephalitis (EEE) and Western equine encephalitis (WEE) are confined to eastern and western parts of North America respectively.
- **EEE** causes a rare but severe form of encephalitis (around 5 cases/year). Bird-mosquito cycle is maintained by *Culiseta melanura* but other mosquitoes such as *Aedes vexans* are involved in transmission to mammals.
- **WEE** occurs more frequently (around 20 cases/year), particularly involving infants, and is transmitted by *Culex tarsalis*.
- **VEE** (Venezuelan equine encephalitis) is confined to South and Central America. It starts with an influenza -like illness but can cause serious encephalitis in people with low immunity.
  - A larger outbreak of VEE had occurred in Venezuela and Colombia in 1995.
  - The usual vector *Culex taenopius*, which has preference for rodents, which was replaced later by *Aedes taeniorhynchus* due to deforestation. The later is more likely to bite humans and large equines.
  - VEE has been used as biological weapon.
- **Vaccine:** Inactivated vaccines have been developed for EEE and WEE whereas for VEE, there are both live attenuated (known as TC-83) and inactivated vaccine(known as C-84) vaccines available.

FLAVIVIRIDAE (MOSQUITO-TRANSMITTED FLAVIVIRUSES)

ENCEPHALITIS GROUP

Japanese B Encephalitis (JE) Virus

Japanese B encephalitis is the leading cause of viral encephalitis in Asia, including India.

History

JE virus was so named because the disease was first seen in Japan (1871) as "Summer encephalitis epidemics" (however, it is now uncommon in Japan) and named 'B' to distinguish it from encephalitis A (encephalitis lethargica/von Economo disease), which was endemic during that time.

Epidemiology

- **Vector:** JE virus is transmitted by bite of *Culex* mosquito
  - *C. tritaeniorhynchus* is the major vector worldwide including India.
  - *C. vishnui* is the next common vector found in India.
- **Transmission cycle:** JE virus infects several extra human hosts, e.g. animals and birds. Two transmission cycles are predominant.
  - Pigs → *Culex* → Pigs
  - Ardeid birds → *Culex* → Ardeid birds
- **Animal hosts**
  - Pigs have been incriminated as the major vertebrate host for JE. JE virus multiplies exponentially in pigs without causing any manifestation. Pigs are considered as the **amplifier host** for JE.
  - Cattle and buffaloes may also be infected with JE virus; although they are not the natural host. They may act as **mosquito attractants**.
  - Horses are probably the only animal to be symptomatic and develop encephalitis following JE virus infection.
  - Humans are considered as dead end; there is no man → mosquito → man cycle (unlike in dengue).
- **Bird hosts:** Ardeid (wading) birds such as herons, cattle egrets, and ducks can also be involved in the natural cycle of JE virus.
- **Age:** 85% of cases occur in children below 15 years (but infants are not affected) and 10% occur in the elderly.
- **Seasonal variation:** Infection due to JE is common in rainy season which coincides with maximum mosquito activity.
  - Temperate areas (summer-autumn)
  - Tropical areas including India (June-October)

Geographical Distribution

Currently, JE is endemic in Southeast Asian region.

- It is increasingly reported from India, Nepal, Pakistan, Thailand, Vietnam and Malaysia.
- Because of immunization, its incidence has been declining from Japan and Korea.
- It is estimated that nearly 50,000 cases occur every year globally with 10,000 deaths.
- **In India:** JE has been reported since 1955.
  - JE is endemic in 15 states; Uttar Pradesh (Gorakhpur district) accounting for the largest burden followed

by Assam, West Bengal, Bihar, Tamil Nadu and Karnataka.
- Annual incidence ranges between 1714 and 6594 and deaths between 367 and 1665.
- In 2014, nearly 1621 cases of JE were reported from India with 290 deaths.

Clinical Manifestations

JE is the most common cause of epidemic encephalitis.
- **Incubation period** is not exactly known, probably varies from 5–15 days.
- **Subclinical infection is common:** JE typically shows iceberg phenomena.
  - Cases are much less compared to subclinical/in-apparent infection with a ratio of 1:300 to 1:1000.
  - Even during an epidemic, the number of cases are just 1–2 per village.
- **Clinical course** of the disease can be divided into three stages:
  1. **Prodromal stage** is a febrile illness; the onset of which may be either abrupt (1–6 hours), acute (6–24 hours) or more commonly subacute (2–5 days).
  2. **Acute encephalitis stage:** Symptoms include convulsions, behavioral changes, meningeal signs or paralysis.
  3. **Late stage and sequelae:** It is the convalescent stage in which the patient may be recovered fully or retain some neurological deficits permanently. Case fatality ratio is about 20–40%.

Vaccine Prophylaxis for Japanese Encephalitis
- **Live attenuated SA 14-14-2 vaccine:**
  - It is prepared from SA 14-14-2 strain of JE virus.
  - It is cell line derived; primary hamster kidney cells are commonly used.
  - Single dose is given subcutaneously, followed by booster dose after 1 year.
  - It is manufactured in China, but now licensed in India.
  - Under Universal Immunization Programme, it is given to children (1–15 years) targeting 83 endemic districts of four states—UP, Karnataka, West Bengal and Assam.
- **Inactivated vaccine** (Nakayama strain and Beijing strain)
  - Both are mouse brain derived and formalin inactivated.
  - Prepared in Central Research Institute, Kasauli (India).
- **Inactivated vaccine (Beijing P3 strain):** It is a cell line derived vaccine.

Other Mosquito Borne Encephalitis Flaviviruses

West Nile Virus

It was first described in West Nile region of Uganda (Africa).
- Since then, it is being transmitted among wild birds by *Culex* mosquitoes in Africa, Middle East, Europe, Asia and recently in America.
- Febrile illness is the most common manifestation (fever, myalgia with rashes on the trunk) but occasionally it can also cause severe encephalitis.

Murray Valley Encephalitis Viruses

It is endemic in northern Australia and Papua New Guinea. Major mosquito vector is *Culex annulirostris*; responsible for human transmission as well as maintenance of bird-mosquito cycle.

St. Louis Encephalitis Viruses

It is transmitted by mosquito (*Mansonia pseudotitillans*). It is related to Japanese B encephalitis virus. It has caused several outbreaks of encephalitis, mainly affecting the United States.

Rocio Encephalitis Viruses

It was first observed in São Paulo State, in 1975. It had caused several epidemics of meningoencephalitis in coastal communities in southern São Paulo, Brazil, during 1975. Transmission is believed to be by *Culex*.

HEMORRHAGIC FEVER GROUP

Dengue Viruses

Dengue virus is the most common arbovirus found in India. It has four serotypes (DEN-1, to DEN-4). Recently, the fifth serotype (DEN-5) was discovered in 2013 from Bangkok.

Vector

Aedes aegypti is the principal vector followed by *Aedes albopictus*. They bite during the day time.
- *A. aegypti* is a nervous feeder (so, it bites repeatedly to more than one person to complete a blood meal) and resides in domestic places, hence is the most efficient vector.
- *Aedes albopictus* is found in peripheral urban areas. It is an aggressive and concordant feeder i.e. can complete its blood meal in one go; hence is less efficient in transmission.
- *Aedes* becomes infective only when it feeds on viremic patients (generally from a day before to the end of the febrile period i.e. 5 days.).
- Extrinsic incubation period of 8–10 days is needed before *Aedes* to become infective. However, once infected, it remains infective for life.
- *Aedes* can pass the dengue virus to its offsprings by transovarial transmission.
- **Transmission cycle:** Man and *Aedes* are the principal reservoirs. Transmission cycle does not involve other animals.

Pathogenesis

Primary dengue infection occurs when a person is infected with dengue virus for the first time with any one serotype.

Months to years later, a more severe form of dengue illness may appear (called **secondary dengue infection**) due to infection with another second serotype which is different from the first serotype causing primary infection.

Antibody Response Against Dengue Virus

Infection with dengue virus induces the production of both neutralizing and non-neutralizing antibodies.

- The **neutralizing antibodies** are protective in nature. Such antibodies are produced against the infective serotype (which last lifelong) as well as against other serotypes (which last for some time). Hence, protection to infective serotype stays lifelong but cross protection to other serotypes diminishes over few months.
- The **non-neutralizing antibodies** last lifelong and are heterotypic in nature; i.e they are produced against other serotypes but not against the infective serotype.
  - Such antibodies produced following the first serotype infection, can bind to a second serotype; but instead of neutralizing the second serotype , it protects it from host immune system by inhibiting the bystander B cell activation against the second serotype.
  - **ADE:** The above phenomena is called **antibody dependent enhancement (ADE)** which explains the reason behind the severity of secondary dengue infection.
  - Among all the serotypes combinations, ADE is remarkably observed when serotype 1 infection is followed by serotype 2, which also claims to be the most severe form of dengue infection.

Clinical Classifications

The Traditional (1997) WHO Classification

This classification divides dengue into three clinical stages:

1. **Dengue fever (DF):** It is characterized by:
   - Abrupt onset of high fever (also called biphasic fever, break bone fever or saddle back fever)
   - Maculopapular rashes over the chest and upper limbs
   - Severe frontal headache
   - Muscle and joint pains
   - Lymphadenopathy
   - Retro orbital pain
   - Loss of appetite, nausea and vomiting
2. **Dengue hemorrhagic fever (DHF):** It is characterized by:
   - High grade continuous fever
   - Hepatomegaly
   - Thrombocytopenia (platelet count < 1 Lakh/ mm^3)
   - Raised hematocrit (packed cell volume) by 20%
   - Evidence of hemorrhages which can be detected by:
     - Positive tourniquet test (>20 petechial spots per square inch area in cubital fossa.
     - Spontaneous bleeding from skin, nose, mouth and gums.
3. **Dengue shock syndrome (DSS):** Here, all the above criteria of DHF are present, and in addition manifestations of shock are present, such as:
   - Rapid and weak pulse
   - Narrow pulse pressure (< 20 mm Hg) or hypotension
   - Presence of cold and clammy skin
   - Restlessness

2009 WHO Classification

This is the most recently described classification by WHO which grades dengue into two stages based on the severity of infection (Fig. 46.1):

1. Dengue with or without warning signs
2. Severe dengue

Factors Determining the Outcome

- **Infecting serotype:** Type 2 is apparently more dangerous than other serotypes.
- **Sequence of infection:** Serotype 1 followed by serotype 2 seems to be more dangerous and can develop into dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS) more often than others.
- **Age:** Though all age groups are affected equally, children less than 12 years are more prone to develop DHF and DSS.

Geographical Distribution

Global Scenario

Dengue is endemic in more than 100 countries with 2.5 billion people at risk.

- Tropical countries of Southeast Asia and Western pacific are at highest risk.
- About 50 million of dengue cases occur every year worldwide, out of which 5 lakh cases (mostly children) proceed to DHF.

Situation in India

Disease is prevalent throughout India in most of the **urban cities/towns** affecting almost 31 states/Union territories.

- Maximum cases have been reported from Kerala, Tamil Nadu, Karnataka, Orissa, Delhi, Maharashtra and Gujarat.
- Outbreaks in rural areas have also been reported from Haryana, Maharashtra and Karnataka.
- In 2014, nearly 36,484 cases were reported, much less than that of previous years (75,808 cases in 2013). Maharashtra followed by Orissa accounted for maximum cases in 2014.
- All four dengue serotypes have been isolated from India. Serotype prevalence varies between seasons and places, but DEN-1 and DEN-2 are widespread. DEN-5 has not been reported yet.

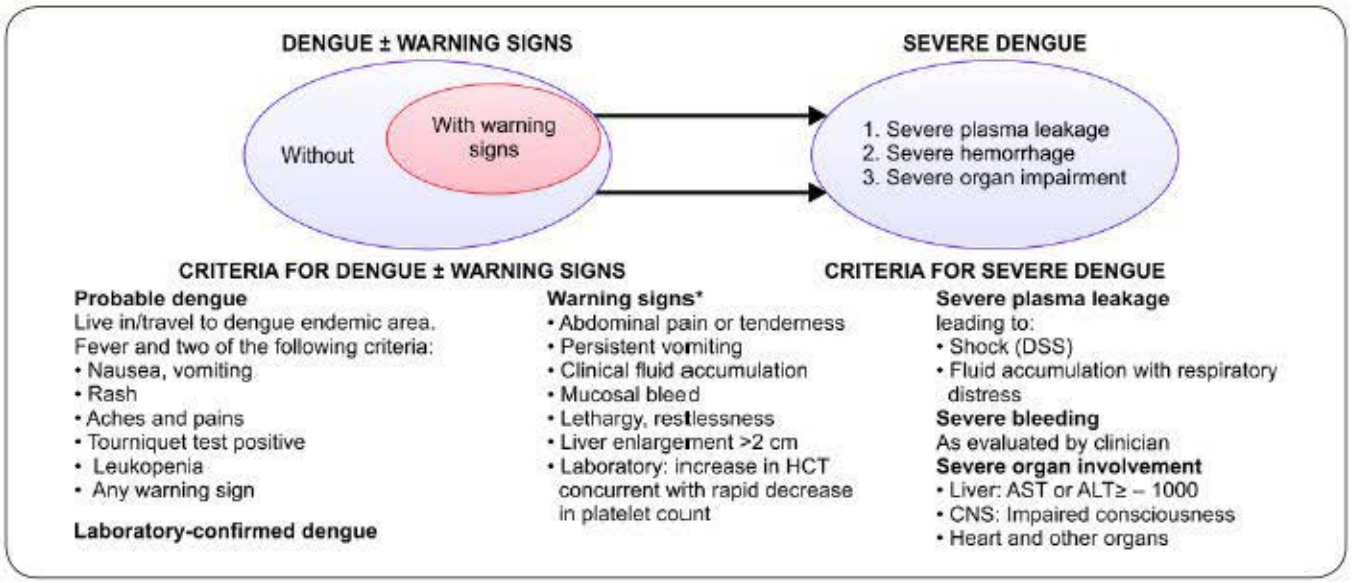


Fig. 46.1: Dengue case classification based on the severity (WHO 2009)

*Requiring strict observation and medical

Abbreviations: HCT, hematocrit; DSS, dengue shock syndrome; AST, aspartate aminotransferase; ALT, alanine aminotransferase; CNS, central nervous system.

Laboratory Diagnosis

The outline of laboratory diagnosis of dengue is similar to that of other arboviruses as described earlier.

NS1 Antigen Detection

ELISA and ICT formats are available for detecting NS1 antigen in serum. They gained recent popularity because of the early detection of the infection.

- NS1 antigen becomes detectable from day 1 of fever and remains positive up to 18 days.
- **Highly specific:** It differentiates between flaviviruses. It can also be specific to different dengue serotypes.

Antibody Detection

- **In primary infection:** Antibody response is slow and of low titer. IgM appears first after 5 days of fever and disappears within 90 days. IgG is detectable at low titer in 14–21 days of illness, and then it slowly increases.
- **In secondary infection:** IgG antibody titers rise rapidly. IgG is often cross reactive with many flaviviruses and may give false positive result after recent infection or vaccination with yellow fever virus or JE. In contrast, IgM titer is significantly low and may be undetectable.
- **In past infection:** Low levels of IgG remain detectable for over 60 years and, in the absence of symptoms, is a useful indicator of past infection.
- **MAC-ELISA** is the most recommended tool available currently for dengue infection. It has a sensitivity and specificity of approximately 90% and 98% respectively. Formats are available for detection of both IgM and IgG separately.
- Rapid tests such as dipstick assays are also available.
- **Other antibody detection assays** used previously are:
  - HAI (Hemagglutination inhibition test)
  - CFT (Complement fixation test)
  - Neutralization tests such as plaque reduction test, neutralization and micro neutralization tests.

Virus Detection

Dengue virus can be detected in blood from 1 day before the onset of symptoms upto 5 days thereafter.

- Virus isolation can be done by inoculation into mosquito cell line or in mouse.
- Detection of specific genes of viral RNA by real time RT-PCR—It is the most sensitive and specific assay, can be used for detection of serotypes and quantification of viral load in blood.

TREATMENT **Dengue**

There is no specific antiviral therapy. Treatment is symptomatic and supportive such as:

- Replacement of plasma losses
- Correction of electrolyte and metabolic disturbances
- Platelet transfusion if needed

Prevention

- **Vaccine:** While no licensed dengue vaccine is available, several vaccines trials are currently being evaluated.

- **Live-attenuated tetravalent vaccine** based on chimeric yellow fever-dengue virus **(CYD-TDV)** has been developed by Sanofi Pasteur Company. It was found to be safe and effective in Phase III clinical trial done in Latin America and is expected to be marketed for human use by late 2015.
- Mosquito control measures.

Yellow Fever Virus

Yellow fever is an acute, febrile illness; severe cases are characterized by liver dysfunction which leads to jaundice (hence the name yellow fever), renal dysfunction and hemorrhage, with high mortality.

- **Geographical distribution:** Yellow fever is endemic in West Africa and Central South America. It is not found in the rest of the World including India.
- **Typing:** At least **seven genotypes** of yellow fever virus have been identified based on genomic sequence, five in Africa and two in South America. However, antigenically it is homogenous, only one serotype is known to exist.

Transmission

- **Vector:** Humans get the infection by the bite of *Aedes aegypti* or the tiger mosquito.
- **Transmission cycle:** Two major cycles of transmission have been recognized:
  1. **Jungle cycle:** This cycle occurs between monkeys and forest mosquitoes. Humans can only get infection occasionally during their forest visits. Monkeys usually suffer from disease.
  2. **Urban cycle:** This cycle occurs between humans and urban mosquitoes (*Aedes aegypti*)

India

Yellow fever has not invaded India yet. However, India has all the potential of developing yellow fever in future because the vector, *A. aegypti*, is widely distributed here, and India has the tropical climatic condition similar to Africa. Various reasons have been hypothesized to explain the absence of yellow fever in India such as:

- **Measures in airport:** Government of India has laid down strict guidelines for vigilance and quarantine of the travelers in the international airports.
  - Unprotected (i.e. unvaccinated) travelers coming from endemic zone to India will be kept in quarantine for the longest incubation period; i.e. 6 days.
  - Breteau index or the *Aedes aegypti* index should be less than one, surrounding 400 meter of an airport. (**Breteau index:** No. of containers showing breeding of *Aedes aegypti* larvae/No. of houses surveyed × 1000).
- Being endemic for dengue, many individuals in India possess dengue antibodies which are found to be cross reactive and hence provide protection against yellow fever. However, it is observed that yellow fever immunization does not protect from dengue.

Period of Communicability

- Man: Patients are infective to mosquito during the first 3–4 days of illness.
- *Aedes:* After an extrinsic incubation period of 8–10 days, the mosquito becomes infective and once infected, remains infective for life.

Clinical Manifestations

Incubation period is about **3–6 days**. Febrile illness occurs in early stage of the disease and characterized by:

- Presence of fever, chills, headache, dizziness, myalgia, and backache-followed by nausea, vomiting, and relative bradycardia.
- Patient is viremic in this stage and may be a source of infection for mosquitoes.

Severe cases are characterized by:

- Hemorrhagic manifestations
- Platelet dysfunction
- Features of liver involvement (hepatitis) are:
  - Mid-zonal necrosis and presence of councilman bodies.
  - Intranuclear inclusions may be seen inside the hepatocytes called **Torres bodies**.
  - Appearance of jaundice.
- Renal dysfunction
- Encephalitis occurs very rarely.
- Mortality rate is high (>20%), especially among children and elderly.

Epidemiology

It is estimated that about 200,000 cases of yellow fever with 30,000 deaths occur annually worldwide and majority of outbreaks (~90%) occur in Africa.

- Epidemics usually occur in humid and semi-humid savanna area adjoining a rain forest.
- **Infection: case ratio:** It ranges from 20:1 to 2:1, during epidemic.
- All age groups are susceptible.

Laboratory diagnosis of yellow fever virus is similar to that of other arboviruses described earlier. Treatment is only by symptomatic care. Preventiive measures include vaccination (see the box) and mosquito control.

Yellow Fever 17D Vaccine

It is a live attenuated vaccine, which is prepared in allantoic cavity of chick embryo(hence it is contraindicated in people having allergy to egg).

- There is no risk of encephalitis (unlike the previously used mouse brain derived inactivated **Dakar vaccine** which was found to be encephalitogenic).
- **In India:** It is prepared in Central Research Institute (CRI), Kasauli.
- **Strict cold chain** has to be maintained during the transport with a temperature range of -30°C to +5°C.
- It is available in **lyophilized form** and has to be reconstituted before use.
- Reconstitution is usually done with diluents such as **physiological saline**. Once reconstituted, it should be used within ½ hour.
- **Dosage:** Single dose, given subcutaneously.
- Vaccine is effective within 7 days of administration, the efficacy lasts for upto 35 years.
- **Validity of yellow fever vaccine certificate:** Certificate is issued after 10 days of vaccination and renewed (i.e. reimmunization) every 10 years. This is the recommendation followed for international travel.
- Cholera and yellow fever vaccine interact with each other, hence should not be given together (3 weeks gap to be maintained).
- **Contraindications** of yellow fever vaccine includes:
  - Children < 9 months, (< 6 months during epidemic)
  - Pregnancy (except during outbreak)
  - HIV infected people
  - People with allergy to egg

TICK-TRANSMITTED FLAVIVIRUSES

ENCEPHALITIS GROUP

Tick Borne Encephalitis (TBE) Viruses

TBE is endemic to most European countries, the Russian Federation and China. They are grouped into three subtypes of viruses:

1. **Central European encephalitis virus** (principal tick vector: *Ixodes ricinus*)
2. **Western Siberian encephalitis virus** (principal tick vector: *Ixodes persulcatus*);
3. **Russian Spring Summer encephalitis** virus (renamed as Far Eastern subtype)
   - **Principal tick vector:** *Ixodes persulcatus*
   - It is abrupt in onset and more severe than the other types.

Inactivated vaccines: Alum precipitated, formalin-inactivated vaccines are available against all subtypes of viruses.

Powassan Encephalitis Viruses

Powassan virus is another tick borne encephalitis virus, transmitted by *Ixodes cookei* in eastern Canada and the USA, where it has been linked to 20 recognized human cases of encephalitis.

Louping-ill Virus

It is an acute viral encephalitic disease of sheep, transmitted by tick (*Ixodes ricinus*). Few human cases have been reported from Europe. The name 'louping-ill' is derived from an old Scottish word describing the effect of the disease in sheep whereby they 'loup' or spring into the air.

HEMORRHAGIC FEVER GROUP

Kyasanur Forest Disease (KFD) Virus

Kyasanur Forest disease virus was identified in 1957 from monkeys from the Kyasanur Forest in Shimoga district of Karnataka, India.

Epidemiology

- **Vector:** Hard ticks (*Haemaphysalis spinigera*) are the vectors of KFD virus and once infected, they remain infected for life. At least 15 species of ticks are involved in transmission among animals.
- **Hosts** Monkeys, rodents and squirrels are common hosts which maintain the virus through animal-tick cycles.
  - Reservoirs are the rats and squirrels.
  - Amplifier hosts are the monkeys, where the virus multiplies exponentially.
  - Man is an incidental host and considered as dead end.
- **In monkeys:** KFD virus has been a cause of epizootics with high fatality in primates especially in monkeys, hence known as **Monkey's disease**.
- **Seasonality:** KFD is increasingly reported in dry months (January-June) which coincides with human activity in forest.
- **Situation in India:** KFD is currently endemic in five districts of Karnataka-Shimoga, North Kannada, South Kannada, Chikkamagaluru and Udupi.
  - **Largest outbreak** had occurred in 1983-84, which has witnessed 2,167 cases with 69 deaths. Currently only focal cases occur at a rate of 100–500 cases per year.
  - From 2003 to 2012 there were 3,263 suspected cases, with 823 confirmed cases and 28 deaths with a case fatality rate of 3.4%.
  - There is a **declining trend** of incidence after the initiation of vaccine in 1999, except for the outbreak that occurred between December 2012 to March 2013 which witnessed 215 suspects with 61 confirmed cases.

Clinical Manifestation in Humans

- Incubation period varies from 3–8 days.
- **First stage (hemorrhagic fever):** It starts as acute high fever with malaise and frontal headaches, followed by

hemorrhagic symptoms, such as bleeding from the nasal cavity, throat, and gums, as well as gastrointestinal bleeding.
- **Second stage** in the form of meningoencephalitis may occur 7–21 days after the first stage.

Laboratory Diagnosis

Diagnosis is made by virus isolation from blood or by IgM antibody detection by ELISA.
- Recently, nested RT-PCR and real time RT-PCR have been developed detecting viral RNA (NS-5/non coding region) in serum samples and can provide early, rapid and accurate diagnosis of the infection.
- Non-specific findings such as leucopenia, thrombocytopenia and decreased hematocrit, albuminuria and abnormal CSF are found in second stage.

Killed KFD Vaccine

A formalin-inactivated chick embryo vaccine has been developed for KFD in the Haffkine institute, Mumbai.
- **Schedule:** Two-doses at interval of 2 months, followed by booster doses at 6–9 months and then every 5 years.
- **Target area:** KFD Vaccine is recommended in endemic areas of Karnataka (villages within 5 km of endemic foci).

Omsk Hemorrhagic Fever Virus

It is endemic in Western Siberia of Russia, in places including Omsk, Novosibirsk and Tyumen.
- It is transmitted by tick.
- Though hemorrhagic fever is the common manifestation, it can occasionally produce neurological involvement.

BUNYAVIRIDAE

The Bunyaviridae family contains about 330 viruses, most of them being arthropod-transmitted with the exception of hantaviruses which are rodent borne (described in Chapter 49).

Morphology: Bunyaviruses have following morphological features:
- Spherical in shape
- Size: 80–120 nm
- It contains a single-stranded, negative-sense segmented RNA (three segments).
- It is an enveloped virus, which has two glycoproteins.

Several members of this family produce mosquito-borne encephalitis or hemorrhagic fevers in humans and animals.

GENUS BUNYAVIRUS

California Encephalitis Virus Complex

This complex comprises of group of 14 antigenically related viruses that cause encephalitis in USA. Important ones include:
- **La Crosse virus:** Accounts for majority of cases; transmitted by *Aedes triseriatus*
- California encephalitis virus
- Jamestown Canyon encephalitis virus

Oropouche Virus

This virus is endemic in Central and South America, characterized by rash and aseptic meningitis. It is transmitted by a midge, *Culicoides paraensis.*

GENUS PHLEBOVIRUS

Sandfly Fever

It is transmitted by sandfly of genus *Phlebotomus pappatasi.*
- It is endemic in subtropical zone of the eastern hemisphere particularly in Southern Europe, North Africa, Eastern Mediterranean, Iraq, Iran, Pakistan and India.
- It is a febrile illness presenting with chills and malaise.
- In India, it has been reported from Aurangabad (Maharashtra).

Rift Valley Fever Virus

- It is endemic in Sub-Saharan Africa, Madagascar, and Egypt
- The most common presentation is fever and myalgia. Hemorrhagic manifestations may be seen rarely.
- It is transmitted by *Aedes* mosquitoes.

GENUS NAIROVIRUS

Crimean Congo Hemorrhagic Fever Viruses

- Tick-borne viral disease (transmitted by tick genera *Haemaphysalis* and *Hyalomma*)
- **Zoonosis:** Affects domestic animals and wild animals.
- In humans, it causes hemorrhagic fever.
- It is endemic in East and West Africa.
- **In India:** Focal cases have been reported from Gujarat in 2011(four cases) and 2013.
- Ribavirin has been found to be effective.

Ganjam Virus

In India, it has been isolated from ticks from various places; most recent was from Pune (2004), earliest was from Ganjam (Odisha, 1955).
- One natural case in humans was reported from Vellore (Tamil Nadu).
- It is antigenically related to Nairobi sheep disease virus of Africa.

REOVIRIDAE

Reoviruses are non-enveloped, spherical in shape and possess a double-stranded segmented RNA. Only a few members under the genera *Coltivirus* and *Orbivirus* are arthropod borne. Remaining viruses are discussed in Chapter 49.

GENUS COLTIVIRUS

Colorado Tick Fever Virus

- The disease is seasonal (June), found almost exclusively in mountain areas of western USA and Canada such as Colorado and Idaho.
- It is characterized by febrile illness, rarely encephalitis.
- The infection is acquired through the bite of an infected tick named *Dermacentor andersoni*.

GENUS ORBIVIRUS

Orungo Virus

It is endemic in sub-Saharan Africa. It is either sub clinical or causes acute febrile illnesses in man. It is mosquito borne (*Aedes*).

Kemerovo Viruses

This causes a paralytic febrile illness accompanied by meningism following a tick-bite (*Ixodes persulcatus*). Cases have been reported from Russia.

RHABDOVIRIDAE

Vesicular Stomatitis Indiana Virus

This virus causes oral mucosal vesicles and ulcers in cattle, horses and pigs similar to hand foot mouth disease. Human infection is rare.

- It is transmitted by sandfly (*Lutzomyia shannoni*).
- **Medical applications:** It has been used for oncolytic therapy (to reduce tumor size) and anti-HIV therapy (can attack HIV infected T-cells).

Chandipura

Chandipura virus has been associated with a number of outbreaks of encephalitic illness in central India.

- It is transmitted by sandfly.
- Children are the most susceptible group for this infection.
- It was first isolated from Chandipura village in Maharashtra, India (1965).
- The most recent outbreaks occurred in Andhra Pradesh and Maharashtra in 2003.
- Further sporadic cases and deaths in children were observed in Nagpur (2007) and Gujarat (2010).

EXPECTED QUESTIONS

I. Essay:

1. Name the arboviruses prevalent in India along with their vectors and discuss in detail about pathogenesis, clinical features and laboratory diagnosis of Japanese B encephalitis virus.
2. Sunita, a 29-year-old female came to casualty with complaints of high grade fever, severe joint pain, back pain and myalgia. Gradually she developed petechial rashes over the body. On examination, she was found to have jaundice, hepatomegaly and a low platelet count (30,000/cmm). A tourniquet test done over the cubital fossa demonstrated 25 petechial spots/square inch area. On enquiry, she told that she has been bitten by the mosquitoes.
   a. What is the clinical diagnosis and how is this disease transmitted?
   b. What are the typical clinical presentation and pathogenesis of this condition?
   c. How will you confirm the diagnosis?

II. Write short notes on:

a. Vaccines for Japanese B encephalitis
b. Chikungunya
c. Kyasanur Forest disease
d. Yellow fever

III. Multiple Choice Questions (MCQs):

1. False statement regarding Japanese B encephalitis is:
a. It is caused by flavivirus
b. Transmitted by *Aedes* mosquito
c. Endemic in India
d. Man is dead-end host.

2. Kyasanur Forest disease is transmitted by:
a. Mite b. Louse
c. Tick d. Mosquito

3. Amplifier host in Japanese B encephalitis is:
a. Man b. *Culex* mosquito
c. Pig d. Horse

4. In dengue infection, earliest detectable number of petechial spots per square inch in cubital fossa should be:
a. >5 b. >10
c. >15 d. >20

5. Certificate of yellow fever vaccination is valid upto:
a. 10 days b. 1 year
c. 5 years d. 10 years

Answers

1. b **2.** c **3.** c **4.** d **5.** d

CHAPTER 47

Rhabdoviruses

Chapter Preview

- Rabies virus
- Other rhabdoviruses

The Family Rhabdoviridae comprises of two genera:

1. **Genus *Lyssavirus*:** Contains rabies virus and rabies-related viruses.
2. **Genus *Vesiculovirus*:** Contains vesicular stomatitis viruses (described under Arboviruses, chapter 46).

RABIES VIRUS

Rabies virus causes a rapidly progressive, acute infectious disease of the central nervous system (CNS) in humans and animals, transmitted from another rabid animal. Although the human cases are few in number, rabies is still considered as a major public health problem because it is almost always fatal.

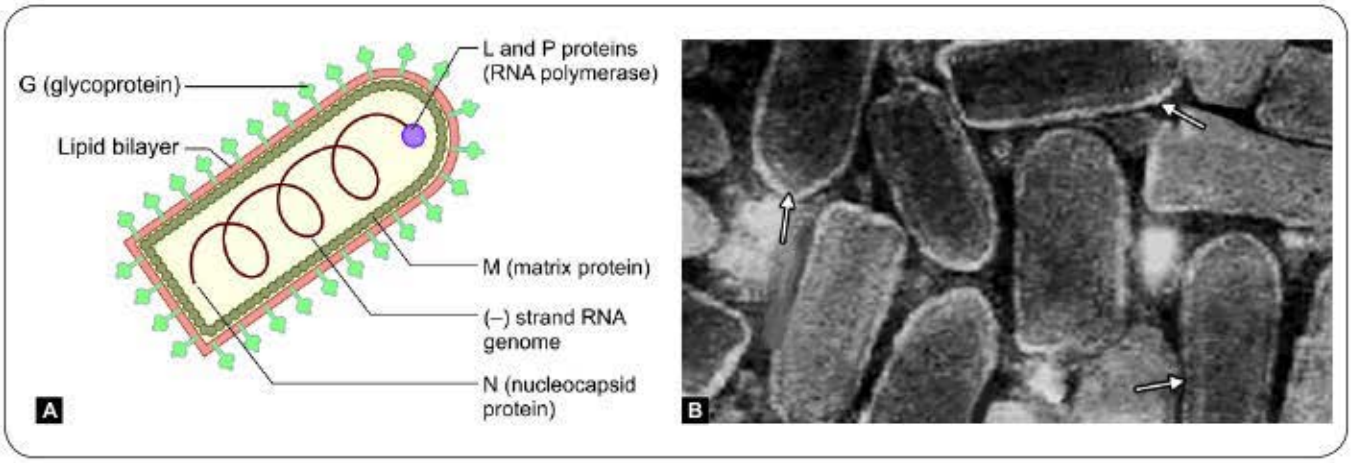
Morphology

Rhabdoviridae family has a unique morphology.

- **Bullet-shaped** (75 nm in width and 180 nm in length)
- **Enveloped:** They have a lipid envelope in which 10 nm long peplomers or spikes (glycoprotein-G) are embedded. Envelope is lined internally by a layer of matrix protein (Figs 47.1A and B).
- **Nucleocapsid** has a helical symmetry and comprises a single-stranded, negative-sense RNA, nucleoprotein and polymerase proteins.

Antigenic Properties

- Rabies virus has only one serotype. However, there are seven antigenic variants that are associated with specific animal reservoirs and found in different geographical areas.
- The variants have minor differences in their antigens (nucleoprotein and glycoprotein G) as well as in their nucleotide sequences.
- Glycoprotein-G is the major factor responsible for rabies virus neuroinvasiveness and pathogenicity. It also possesses hemagglutinin activity (Table 47.1).



Figs 47.1A and B: Rabies virus. **A.** Schematic diagram; **B.** Electron micrograph (*arrows showing*)

Source: Public Health Image Library, B. ID# 5611/Fred. A. Murphy/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TABLE 47.1: Major antigens of rabies virus

Glycoprotein G	Nucleoprotein
These are peplomers or spikes embedded in envelope	These are capsid proteins associated with viral RNA
Species-specific	Group-specific and it cross reacts with that of rabies related viruses.
Role in pathogenesis: It binds to acetyl choline receptors in neural tissues, which is the first step of pathogenesis (attachment)	Does not have any role in pathogenesis
Diagnostic role: **Antibody detection (HAI):** It induces hemagglutination inhibiting antibodies which can be detected in patient's serum by hemagglutination inhibition (HAI) test	▪ **Antibody detection (CFT):** It induces complement fixing antibodies which can be detected in patient's serum by complement fixation test (CFT) ▪ **Antigen detection:** Antiserum prepared against the purified nucleocapsid is used in direct IF test
Role in immunity: It induces neutralizing antibodies which are protective in nature and also stimulates cytotoxic T cells	Antibodies are not protective.
Role in vaccination: Being protective in nature, the purified form of the antigen can be used in subunit vaccine	Not used for vaccination

Animal Susceptibility

Rabies virus has a wide host range; infects all warm-blooded animals, including humans.

- **Animal susceptibility to rabies virus:** Susceptibility varies among various animals.
  - Very highly susceptible animals: Foxes, jackals, wolves and cotton rats.
  - Highly susceptible animals: Rabbits, cattle, cats, hamsters, raccoons and bats.
  - Moderately susceptible animals: Dogs, goats, sheep, horses and non-human primates.
  - Low susceptible animals: Opossums.
- Rabies virus also undergoes certain changes when it is serially propagated in animals.
- **Street viruses:** These are freshly isolated strains in the laboratory. They mimic the wild viruses; show long and variable incubation periods and produce intracytoplasmic inclusion bodies (Table 47.2).
- **Fixed viruses:** When street viruses are propagated in rabbits by serial brain-to-brain passage; they lose certain properties and become fixed strains (Table 47.2).

TABLE 47.2: Differences between street and fixed rabies viruses

Street viruses	Fixed viruses
Freshly isolated	Isolated after serial intracerebral passage in rabbits/cell lines
Produce Negri body	Do not produce Negri body
Affect salivary glands	Do not affect salivary glands
Pathogenic	Not pathogenic (except- if not inactivated properly)
Incubation Period: 1–3 months (20–90 days)	Incubation Period: 4–6 days
Produce disease	Used for vaccine

  - They do not produce inclusion bodies.
  - They do not multiply in extraneural tissues.
  - They do not infect salivary gland.
  - They multiply rapidly, and the incubation period is shortened to 4–6 days, hence these strains are best used for vaccination.

Pathogenesis (Fig. 47.2)

Transmission

- **Bite:** Rabies virus is usually transmitted to humans by the bite of an infected animal. However, other modes of transmission have also been rarely reported.
  - **Dog bite** is the most common mode.
  - **Other animal bites** can also transmit rabies: Monkey, sheep, goat, cat, buffalo and horse (except rat bite and human bite).
  - **Bat bite** (mostly goes unnoticed): Migrating fruit-eating bats are the most common bats that transmit rabies in America.
  - Human-to-human transmission is theoretically possible, but is extremely rare.
- **Non-bite exposures** are rare such as:
  - Lick on abrasion or mucosa.
  - Inhalation of virus containing aerosols generated from infected bats.
  - Corneal transplantation.

Spread of the Virus

- **Multiply locally:** Virus starts replicating locally at the site of inoculation in muscle or in connective tissue.
- **Viral entry to peripheral neurons:** Virus binds to nicotinic acetylcholine receptors present at neuromuscular junctions.
- **Neuronal spread:** Rabies virus spreads centripetally along the peripheral motor nerves via retrograde fast axonal transport, at a rate up to 250 mm/day.
- It reaches dorsal root ganglia of the spinal cord, and then ascends upward towards CNS.
- **Central nervous system (CNS) infection:** It rapidly disseminates to various parts of CNS, most common site

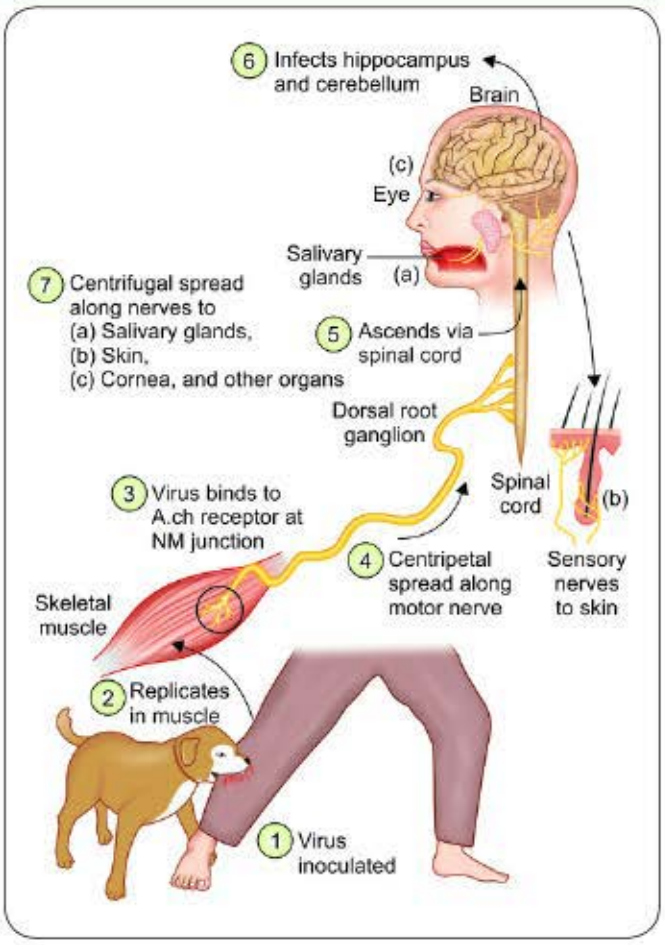


Fig. 47.2: Pathogenesis of rabies

being the area of mental system such as hippocampus and cerebellum.

- **Centrifugal spread:** From CNS, the virus spreads along the sensory and autonomic nerves to various tissues such as salivary glands (maximum titer) followed by pancreas, kidney, heart, retina, and cornea. However, viremia does not occur.
- **Shed in saliva:** Rabies virus is shed in the saliva of rabid animals which acts as the source of infection to other animals. Viral shedding also occurs in human saliva, but human to human transmission has not been confirmed yet.

Pathological Changes

Histopathological changes produced in brain parenchyma of rabies infected patients include:

- Mononuclear cell infiltration
- Perivascular cuffing of lymphocytes
- Babes nodules consisting of glial cells
- Negri bodies

Negri Bodies

These are intracytoplasmic eosinophilic inclusions in brain neurons that are composed of rabies virus proteins and viral RNA.

- Detection of Negri bodies confirms post mortem diagnosis of rabies.
- Negri bodies are commonly observed in Purkinje cells of the cerebellum and in pyramidal neurons of the hippocampus, and are less frequently seen in cortical and brainstem neurons.

Clinical Manifestations

Incubation Period

Incubation period is prolonged and variable, average being 20–90 days (ranges from 1 week to 19 years).

It is inversely related to the distance for the virus to travel from the site of inoculation to CNS. Hence the incubation period is usually shorter in—

- Children than in adults
- Bites on head, neck and upper limbs than legs
- Short people
- Severe lacerations
- Presence of genetic predisposition
- Low host immunity
- **Virus:** High dose of inoculum ↑ virulence of the strain.

The clinical spectrum can be divided into three phases:

1. Short Prodromal Phase

It lasts for 2–10 days, characterized by non-specific symptoms such as fever, malaise, anorexia, nausea, vomiting, photophobia, sore throat, abnormal sensation (paresthesia, pain, or pruritus) around the wound site.

2. Acute Neurologic Phase

This may be either encephalitic type (80%) or paralytic type (20%).

- **Encephalitic rabies:** It lasts for 2–7 days, and is characterized by:
  - **Hyperexcitability:** Anxiety, agitation, hyperactivity, bizarre behavior and hallucinations may be seen.
  - **Lucid interval:** Period of hyperexcitability is typically followed by complete lucidity that becomes shorter as the disease progresses.
  - **Autonomic (sympathetic) dysfunction** features may be seen such as ↑lacrimation, ↑salivation (leads to ***foaming*** at the mouth), ↑ perspiration, gooseflesh, cardiac arrhythmia and priapism.
  - **Hydrophobia** (fear of water) or **aerophobia** (fear of air)—The act of swallowing precipitates an involuntary, painful spasm of the respiratory, laryngeal, and pharyngeal muscles. These symptoms are probably due to dysfunction of infected brainstem neurons.

- **Paralytic or dumb rabies:** This occurs in 20% of cases, especially in people who are partially vaccinated or infected with bat rabies virus. It is characterized by flaccid paralysis, often begins in the bitten limb and progressing to quadriparesis with facial paralysis. However, hydrophobia and other features of encephalitic rabies are typically absent.

3. Coma and Death

Following acute neurological phase, patient develops coma that eventually leads to death within 14 days. Patients with paralytic rabies may survive longer up to 30 days. However, death is almost certain. Recovery and survival are extremely rare.

LABORATORY DIAGNOSIS — Rabies

- Antigen detection from hair follicles at nape of the neck and form corneal smear—by direct IF test.
- Viral Isolation by:
  - Mouse inoculation
  - Cell lines inoculation—Mouse neuroblastoma and BHK cell lines.
- Antibody detection from serum and CSF—by MNT, RFF-IT, FAVN, IFA, HAI and CFT.
- Viral RNA detection—by RT-PCR.
- Negri body detection in histopathological staining of brain biopsies (hippocampus)—for postmortem diagnosis of rabies.

Laboratory Diagnosis

Rabies Antigen Detection

Direct immunofluorescence test (direct-IF) can be performed to detect rabies nucleoprotein antigens in specimens by using specific monoclonal antibodies tagged with fluorescent dye.

- The best specimen is hair follicle of nape of neck (most sensitive).
- Corneal impression smear can also be used. It is usually positive in late stage with a sensitivity of 30%.

Viral Isolation

- **Mouse inoculation:** Intracerebral inoculation into suckling mice can cause encephalitis and death. The brain biopsies of the inoculated animal are examined for the presence of Negri bodies and rabies antigen.
- **Cell lines:** Mouse neuroblastoma cell lines and baby hamster kidney (BHK) cell lines are the preferred cell lines for rabies virus isolation.
  - They can yield virus (2–4 days) much faster than that of mice inoculation.
  - Viral growth in the cell lines can be detected by direct-IF test using specific antiserum.

Antibody Detection

Detection of CSF antibodies is more significant than serum antibodies.

- Serum antibodies appear late and can also be present after vaccination.
- CSF antibodies appear early and they are produced only in rabies-infected individuals but not in response to vaccination.
- Various antibody detection tests include:
  - Mouse neutralization test (MNT)
  - Rapid fluorescent focus inhibition test (RFFIT)
  - Fluorescent antibody virus neutralization test (FAVN)
  - Indirect fluorescence assay (IFA)
  - Hemagglutination inhibition test (HAI)
  - Complement fixation test (CFT)

Viral RNA Detection

Reverse transcription-polymerase chain reaction (RT-PCR) can be used to amplify genes of rabies virus RNA from the brain tissue. It is the most sensitive and specific assay available at present for the diagnosis of rabies.

Negri Body Detection

It is useful for postmortem diagnosis of rabies.

- It is an intracytoplasmic eosinophilic inclusion with characteristic basophilic inner granules.
- It is sharply demarcated, spherical to oval, and about 2–10 μm in size.
- Most common sites of Negri bodies are neurons of cerebellum and hippocampus; however, they can also be less frequently seen in cortical and brainstem neurons.
- Commonly used stains are histological stains such as H and E (Fig. 47.3) and Sellers stains (basic fuchsin and methylene blue in methanol).

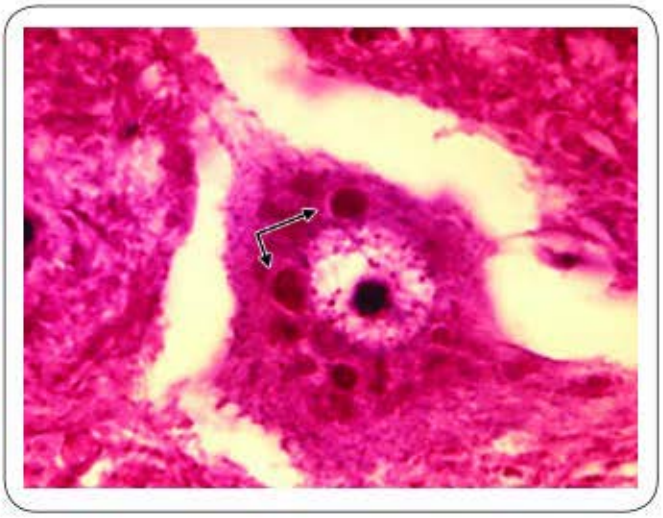

Fig. 47.3: Negri bodies in brain biopsy by H and E stain (*arrow showing*)

Source: Public Health Image Library, ID# 3377//Dr. Daniel P. Perl/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Immunohistochemistry Peroxidase labelled specific antibodies are used to detect the viral inclusions in formalin-fixed tissues. It is more sensitive and specific than histological staining methods.
- Negri body detection is pathognomonic of rabies. However, it may not be detected in 20% of cases.
- Therefore, the absence of Negri bodies does not rule out the diagnosis of rabies.

TREATMENT **Rabies virus**

There is no specific treatment for rabies. Symptomatic treatment may prolong life, but the outcome is almost always fatal.

- Isolation: Patient should be isolated in a quiet room, protected as far as possible from external stimuli such as bright light, noise, water or cold air which can precipitate spasms.
- Sedatives and anti-anxiety drugs such as morphine can be used.
- Hydration and urination should be properly maintained.

Prognosis

Mortality in rabies is almost 100%; however it is preventable by administration of post-exposure therapy during the early incubation period. There are seven well-documented cases who survived from rabies—mostly because of taking rabies vaccine in the early incubation period.

Prevention of Human Rabies

Post-exposure prophylaxis (PEP) includes local wound care, and both active and passive immunization.

Local Wound Care

It can greatly decrease the risk of rabies if initiated immediately.

- **Physical cleansing:** All bite wounds and scratches should be washed thoroughly with soap and water. Punctured wound should be irrigated by catheters.
- **Chemical inactivation:** Antiseptics such as povidone iodine or alcohol can be used to inactivate the residual viruses.
- **Biological neutralization** of the virus by giving anti-rabies immunoglobulin.
- Devitalized tissues should be debrided.
- Tetanus prophylaxis should be given.
- Antibiotic treatment is initiated to prevent secondary bacterial infection.
- **Suturing is contraindicated:** Bite wounds should not be immediately sutured, as it may help in spreading of the virus into deeper tissues.

Passive Immunization (Rabies Immunoglobulin)

Rabies immunoglobulins (RIG) have the property of binding with the rabies virus, thereby resulting in neutralization and thus loss of infectivity of the virus. Hence RIGs are usually administered locally at the site of exposure.

- **Two types** of RIGs are available:
  - **Equine rabies immunoglobulin (ERIG):** It is given at dose of 40 IU/kg . Being heterologous in origin (horse), it is associated with serum sickness.
  - **Human rabies immunoglobulin (HRIG):** It is given in a dose of 20IU/kg. It is devoid of side effects.
- **Maximum volume** of RIGs should be infiltrated into and around the bite wound(s); remaining volume if any should be administered by deep intramuscular injection at a site distant from the vaccine injection site.

Active Immunization (Rabies Vaccine)

Rabies vaccine can be categorized into—neural and non-neural vaccine.

Neural Vaccines

These are derived from the nervous tissues of animals infected with the fixed rabies virus. It was developed by Louis Pasteur and modified later.

- Neural vaccines were in use in India for quite a long time, but they are encephalitogenic, poorly immunogenic and are associated with serious risk of neurological complications. They are no longer in use since 2004 and have been replaced by non-neural vaccines.
- Examples include:
  - **Semple vaccine:** It is derived from infected sheep brain, inactivated with phenol.
  - **Beta propiolactone (BPL) vaccine:** It is a modified Semple vaccine which is inactivated with beta propiolactone instead of phenol.
  - **Infant mouse brain vaccines:** It is derived from infected neural tissue of newborn mice.

Non-neural Vaccines

Non neural vaccines include egg derived, recombinant glycoprotein and cell line derived vaccines; of which the later two are currently used in India.

- **Egg-derived vaccines:** Allantoic cavity of embryonated eggs is the best site for the preparation of rabies vaccine.
  - **Purified duck embryo vaccine (PDEV):** Duck eggs being larger, give a higher yield than that of hen. Unlike the neural vaccine, it is less reactogenic, but it is less antigenic too; hence multiple (16–25) doses have to be given to obtain a satisfactory antibody response. It is no longer manufactured.
  - **Live attenuated chick embryo vaccine** such as Flury strain was in use before for vaccinating animals, but now it is obsolete.
- **Recombinant viral vaccine:** Vaccinia virus carrying the rabies surface glycoprotein gene has been developed.

It is given orally, has been successful for immunizing animals, but still in experimental stage for human use.

- **Cell culture-derived vaccines** are the most recommended vaccine for prevention of rabies. They are highly immunogenic and devoid of neurological complications. Three vaccines are available in India.
  - Purified chick embryo cell (PCEC) vaccine: It is prepared from chicken fibroblast cell line.
  - Purified Vero cell (PVC) vaccine: It is prepared from Vero cell line.
  - Human diploid cell (HDC) vaccine: It is derived from WI-38 (human embryonic lung fibroblast cell line).

National Guideline on Rabies Prophylaxis

(Adapted from National Center for Disease Control, India)

Regimen for Post-exposure Prophylaxis

- **IM regimen** or **Essen regimen (1-1-1-1-1):** Five doses of intramuscular (IM) injections; one dose (0.5 or 1 mL) each given on days 0, 3, 7, 14 and 28. Day 0 indicates the date of administration of first dose of vaccine and may not be the date of rabies exposure/animal bite.
- **ID regimen** (or Thai Red Cross Schedule) (2-2-2-0-2): This involves intradermal (ID) injection of 0.1 mL of reconstituted vaccine on two sites per visit on days 0, 3, 7 and 28.
- **Potency:** Single intramuscular dose should have a minimum potency of 2.5 IU.
- **Site of injection:**
  - Deltoid region is ideal site.
  - Gluteal region is not recommended because fat retards the absorption of antigen.
  - Infants and young children—Antero lateral part of the thigh is the preferred site.
- **Risk category:** Depending on the type of exposure, the PEP varies (Table 47.3).
  - Vaccine is indicated for category II and III bites.
  - Rabies immunoglobulin may be considered if the exposure is of category III type.

Regimen for Pre-exposure Prophylaxis

- It is recommended for high risk groups like laboratory staff handling the virus and infected material, clinicians or any person attending to human rabies cases, veterinarians, animal handlers and travellers from rabies free areas to rabies endemic areas.
- **Three doses** are given on day—0, 7, and 21 or 28 days either by IM (0.5 mL) or ID (0.1 mL) schedule.
- Antibody titer should be checked every 6 months for 2 years and thereafter every 2 yearly. Booster dose is given if the titer falls below 0.5 IU/mL.

TABLE 47.3: Risk categorization and recommended anti-rabies prophylaxis

Category of risk	Type of exposure	Recommended prophylaxis (WHO**)
Category I (No risk)	▪ Touching, or feeding of animal ▪ Licks on intact skin	▪ No treatment needed if history is reliable
Category II (Minor risk)	Minor scratches or abrasions without bleeding or nibbling of uncovered skin	▪ Wound management ▪ Rabies vaccine ▪ Observe the dog for 10 days
Category III (Major risk)	▪ Single or multiple transdermal bites with oozing of blood ▪ Licks on broken skin (fresh wounds) or mucous membrane ▪ Bite by wild animals /bat	▪ Wound management ▪ Rabies immunoglobulin ▪ Rabies vaccine ▪ Observe the dog for 10 days*

*Vaccine may be discontinued if animal (dogs and cats) is healthy after 10 days of bite. Other animals are humanly killed and tissue is examined for detection of rabies antigen/Negri body in brain biopsies.

**In India post exposure prophylaxis is indicated following exposure to any animal bite except rats.

Regimen for Post-exposure Prophylaxis in Previously Vaccinated Individuals

This depends on the antibody titer and the severity of the wound bite.

- Severe bite or titer unknown: 3 doses are given on—0,3 and 7 days.
- **Less severe bite or titer >0.5 IU/mL:** 2 doses given on 0 and 3 days.
- Immunoglobulins are usually not needed.

Epidemiology

Rabies is an enzootic and epizootic disease of both wild and domestic animals worldwide.

- **Worldwide**, rabies is endemic in >150 countries. About 55,000 deaths occur due to human rabies each year, maximum in rural areas of Asia and Africa. India accounts for 20,000 deaths/year. However, rabies may be grossly underreported in many countries including India.
- **Source:** Infected dog is the source of infection in 99% of cases. Virus present in saliva from 3–4 days before the onset of symptoms till death of the dog.
- **Age:** Though all ages are affected, children aged 5–15 years are at greater risk.
- **Rabies-free countries:** Defined as the areas where no case of indigenously acquired rabies has occurred in man or animals for 2 years. There are few countries/places which are rabies-free:
  - Australia and Antarctica

- Britain
- Iceland and Ireland
- China—(Taiwan), Cyprus
- Japan, Malta
- New Zealand
- India—Andaman and Nicobar Islands, Lakshadweep

Rabies in Dogs

As 90% of human rabies is caused by dog bites, control of rabies in dogs is the most important step to prevent human rabies.

Clinical features

- Rabies in dog has a typical clinical course. Incubation period varies 3–8 weeks (ranges from 10 days to few years). Like in humans, two types of manifestations may be seen.
  - **Furious Rabies (or Mad Dog Syndrome):** It is characterized by:
    - Changes in behaviour: Dog loses fear of people, become very aggressive, bites without provocation
    - Running amok-wandering aimlessly
    - Change in tone of the dog's bark
    - Fever and loss of appetite
    - Excessive salivation and foaming at mouth
    - Paralytic stage towards the later stage
    - Coma and death within a week
  - **Dumb or paralytic rabies:** Predominantly paralytic features are seen, but excitation symptoms are absent.
- **Control of rabies in dogs:** Most logical and cost effective approach for control of urban rabies is elimination of stray dogs and mass immunization of at least 80% dogs in an area.
- **Immunization of dogs:** It is the most important weapon in rabies control. All dogs should receive a primary immunization at 3–4 month of age, followed by boosters as per the type of vaccine used. Vaccines commonly used in dogs are:
  - BPL inactivated neural vaccine
  - Live attenuated chick embryo vaccine
  - Oral recombinant glycoprotein vaccine

OTHER RHABDOVIRUSES

Other Lyssaviruses (Rabies-like Viruses)

In addition to rabies virus, Genus *Lyssavirus* also comprises of a number of other rabies related viruses.

Rabies related viruses have been isolated from bats in Africa, Europe, and Australia and have produced few cases of human disease indistinguishable from rabies.

- European bat *Lyssavirus* 1 and 2 (in Europe)
- Australian bat *Lyssavirus* (in Australia)
- Duvenhage virus (in Africa)
- Lagos bat virus (in Africa)
- Mokola virus (in Africa)-isolated from shrews (not bat)

EXPECTED QUESTIONS

I. Essay:

1. Mr Michel, a 25-year-old Australian visited his local doctor complaining of difficulty in swallowing liquids, loss of appetite and restlessness. Patient history revealed that he is a photo-journalist for a travel magazine. He had a travel history to India one month back and did mention being bit by a street dog in Pondicherry. He did not seek medical care because he thought it would be too complicated to deal with while overseas and the bite was very small.
   a. What is the most probable etiological diagnosis?
   b. Draw a labelled diagram of the morphology of the causative agent of this condition.
   c. Discuss the pathogenesis and laboratory diagnosis of the above condition.
   d. Name the vaccines available for human use.

II. Multiple Choice Questions (MCQs):

1. **Anti-rabies vaccine is prepared from:**
   a. Street virus
   b. Fixed virus
   c. Live virus
   d. Wild virus
2. **For the treatment of case of class III dog bite, all of the following are correct except:**
   a. Give immunoglobulin for passive immunity
   b. Give anti-rabies vaccine
   c. Immediately stitch wound under antibiotic coverage
   d. Immediately wash wound with soap and water
3. **All of the following rabies vaccines are commercially available for human use except:**
   a. Purified chick embryo cell vaccine (PCEC)
   b. Human diploid cell vaccine
   c. Vero continuous cell vaccine
   d. Recombinant glycoprotein
4. **Rabies is identified by:**
   a. Guarneri bodies
   b. Negri bodies
   c. Cowdry A bodies
   d. Paschen body

CHAPTER 48

HIV and Other Retroviruses

Chapter Preview

- Retroviruses
  - Human immunodeficiency virus (HIV)
  - Human T cell lymphotropic virus (HTLV)

RETROVIRUSES

Retroviruses possess a unique enzyme called **reverse transcriptase** that directs the synthesis of DNA from the viral RNA after they infect into a host cell.

The family Retroviridae includes three subfamilies and seven genera; out of which two genera contain viruses that are pathogenic to humans (Table 48.1).

- Genus *Lentivirus:* Contains human immunodeficiency virus (HIV)-1 and 2.
- Genus *Deltaretrovirus:* Contains human T cell lymphotropic virus-1 (HTLV-1)

Types

Based on the mode of spread from one host cell to other, retroviruses are grouped into two types:

1. **Exogenous retroviruses:** They spread horizontally from one host cell to other. Example include most pathogenic retroviruses (HIV and oncogenic HTLV-1).
2. **Endogenous retroviruses:** They are transmitted vertically from parent host cells to offspring, by integrating the provirus into host cell chromosome.
   - The proviral DNA behaves like a cellular gene and is subjected to regulatory control by the host cell.
   - They are usually silent and do not cause any disease or malignancies.

HUMAN IMMUNODEFICIENCY VIRUS (HIV)

Human immunodeficiency virus (HIV) is the etiologic agent of Acquired Immunodeficiency Syndrome (AIDS)- the biggest threat to mankind in last three decades.

History/Origin of AIDS

The first case of AIDS was described from New York (USA) in 1981; which was soon followed by the discovery (isolation) of HIV-1 from Pasteur Institute, Paris in 1983.

- HIV in humans was believed to be acquired from chimpanzee (*Pan troglodytes troglodytes*) by the cross-species infections of simian counterpart of HIV in rural Africa (simian immunodeficiency virus or SIVcpz).
- It has been postulated that though such zoonotic transmission to humans was going on repeatedly over many years in the past, only by the late 20th century the

TABLE 48.1: Classification of retroviruses

Subfamily	Genus	Example(s)	Feature
Oncovirinae	*Alpharetrovirus*	Rous sarcoma virus	Non-pathogenic to man Contains *src* oncogene
	Betaretrovirus	Mouse mammary tumor virus	Non-pathogenic to man
	Gammaretrovirus	Abelson murine leukemia virus	Non-pathogen to man Contains *abl* oncogene
	Deltaretrovirus	HTLV-I	Causes T cell lymphoma and neurologic disease in man
	Epsilonretrovirus	Walleye dermal sarcoma virus	Non-pathogenic to man
Lentivirinae	*Lentivirus*	HIV-1 and 2	Cause AIDS
Spumavirinae	*Spumavirus*	Simian foamy virus	Non-pathogenic to man

Abbreviations: HTLV-1, human T cell lymphotropic virus-1; HIV, human immunodeficiency virus; AIDS, acquired immunodeficiency syndrome.

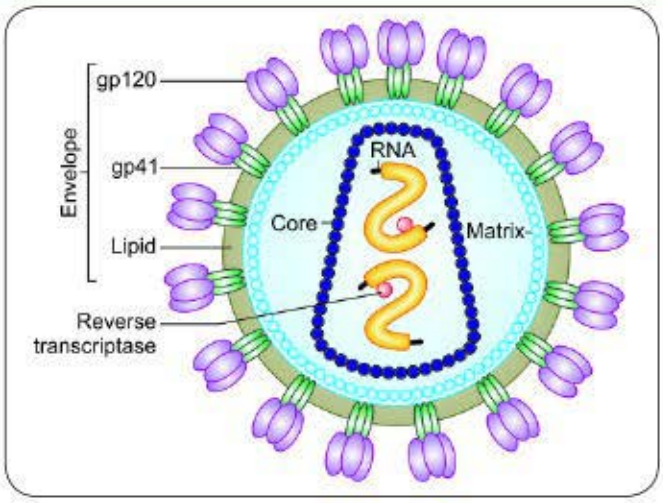

Fig. 48.1: Structure of HIV

virus underwent changes which enabled it to adapt to human environment and to reach the epidemic level.

Morphology

HIV and other lentiviruses have a unique structure (Fig. 48.1): They are spherical and 80–110 nm in size,

- **Envelope:** HIV is an enveloped virus. The envelope is made up of—
  - Lipid part: It is host cell membrane derived.
  - Protein part: It has two components:
    1. Glycoprotein: 120 (gp 120): They are projected as knob like spikes on the surface and;
    2. Glycoprotein: 41 (gp 41): They form anchoring transmembrane pedicles.
- **Nucleocapsid**: Capsid is icosahedral in symmetry, made up of core protein. Inside, there is a dense cylindrical inner core which encloses:
  - **RNA:** Two identical copies of single-stranded positive sense linear RNA.
  - Viral enzymes such as reverse transcriptase, integrase and proteases which are closely associated with HIV RNA.

HIV Genes and Antigens

HIV contains three structural genes—*gag, pol,* and *env* and six non-structural or regulatory genes.

Structural Genes

Structural genes code for various components of the virus.

- The *gag* gene codes for the core and shell of the virus. It is expressed as a precursor protein, p55* which is cleaved into three proteins,
  - p17 constitutes the matrix or shell antigen
  - p24 and p15- constitute the core antigens
- The *pol* gene codes for viral enzymes such as reverse transcriptase, protease and integrase. It is expressed as a precursor protein, which is cleaved into proteins p32(integrase), p51(reverse transcriptase) and p66.
- The *env* gene codes for the envelope glycoprotein (gp 160), which is cleaved into two components:
  - gp 120: It is the main receptor of HIV that binds to CD4 molecules on host cell to initiate infection.
  - gp41: It is the fusion protein.

Non-Structural Genes

Non-structural genes regulate viral replication and are important in disease pathogenesis *in vivo*.

- *Tat* is a transcriptional transactivator gene, that is essential for HIV-1 replication.
- *Nef* (negative factor gene): It down regulates the CD4 expression on the host cell surface.
- *Rev* (regulator of virus gene): It enhances expression of structural proteins.
- *Vif* (viral infectivity factor gene): It influences the infectivity of viral particles.
- *Vpu* gene: It promotes the CD4 degradation and release of progeny viruses from the host cell and are type specific; expressed only by HIV-1.
- *Vpr* gene: It increases the transport of viral genome into the nucleus and also arrests host growth.
- *Vpx* is found in HIV-2 (and SIV), but not in HIV-1. It is closely related to *Vpr*.
- *LTR* (long terminal repeat) sequences are present on both the ends; provide promoter, enhancer and integration signals.

Antigenic Variation and Diversity

HIV shows extensive antigenic diversity because of undergoing high rates of mutation.

- This is believed to be due to the error prone nature of reverse transcriptase enzyme.
- Different mutants will be selected under different conditions (host factors, immune responses and tissue types).
- Although mutations may occur in any genes, most notably it is observed in *env* gene.
- Unfortunately, envelope proteins happen to be the major target against which antibodies are produced. Hence mutations in *env* gene is the main reason which explains why:
  - HIV evades the host's immune response.
  - Vaccination against HIV is extremely difficult.

*In HIV, the proteins and glycoproteins are indicated by their mass which is expressed in kilodaltons (e.g. p55- means protein with molecular weight 55kDa.)

HIV Serotyping

Based on sequence differences in *env* gene, HIV comprises of two serotypes HIV-1 and 2.

HIV-1

It is divided into three distinct groups (M, N, and O). Recently, a HIV strain related to gorilla SIV was identified in a Cameroonian woman in 2009 and has been proposed as *group P*.

- 'M' is the dominant group worldwide. It comprises of ten **subtypes** or "clades" (A-J).
- Subtypes are sometimes further split into **sub-subtypes** such as A1 and A2 or F1 and F2.
- There are also "**circulating recombinant** forms" or CRFs derived from recombination between different subtypes. For example, CRF01_AE is a recombination between subtypes A and E.
- The same infected host may have a group of closely related viral subtypes and/or CRF at a given time which are collectively called as **quasispecies**.
- HIV-1 subtypes or clades do not vary in pathogenesis or biology; but they differ in geographical distribution and transmission.
- **Geographical distribution**
  - Subtype A is common in West Africa.
  - Subtype B is predominant in Europe, America, Japan, and Australia.
  - Subtype C is the most common form worldwide (47%). It is also the dominant form in Southern and Eastern Africa, India, and China.
  - In Cameroon (West Africa), all known HIV groups and subtypes are found. It is probably, considered as the place of origin of the virus.
- **Transmission:** Asian and African subtypes (C and E) are more readily transmitted heterosexually where as American strains (subtype B) preferentially spread through blood and homosexual contact.

HIV-2

It comprises of eight groups (A–H); they are confined to Africa and some time in other places including India. Group A is the most common form.

Disinfection and Inactivation

HIV is inactivated completely by treatment with:

- Household bleach (10%) for 10 minutes, used for infected needle or syringe
- Ethanol (50%), isopropanol (35%)
- Lysol (0.5%) for 10 minutes
- Para formaldehyde (0.5%): For 10 minutes
- Hydrogen peroxide (0.3%) for 10 minutes
- Heating: Serum inactivation at 56°C for 10 minutes (dried blood or lyophilized blood products would need—68°C for 72 hours)
- Extremes of pH (pH 1.0, pH 13.0)

TABLE 48.2: Transmission of HIV

Route of transmission	Risk of transmission (Worldwide, %)	% of total transmission	
		World	India*
Blood transfusion	90–95	5	1**
Parent to child	20–40	10	5.4
Sexual intercourse	**0.1–1**	**75**	**88.9**
Vaginal	0.05–0.1	60	87.4 (heterosexual)
Anal	0.065–0.5	15	1.5 (homosexual)
Oral	0.005–0.1	Rare	Not reported
Injection drug abuse	0.5–1.0	10	1.6%
Needle stick exposure	0.3	0.1	1**
Unknown	–	–	3

**Courtesy:* NACO (National AIDS Control Organization, India), ** 1% for Needle stick exposure + blood transfusion together

Pathogenesis

Mode of Transmission (Table 48.2)

- **Sexual mode** is by far the most common mode of transmission, accounts for 75% of total cases in the world.
  - Heterosexual route (male to female via vaginal coitus) is the commonest mode.
  - However, the risk of transmission through sexual route is minimal (0.1–1% per coitus).
  - Anal intercourse (among homosexual males or even male to female) has higher risk of transmission than vaginal intercourse.
- **Blood transfusion**, though is the least common mode of transmission (5%) but the risk of transmission is maximum (90–95%).
- **Percutaneous/mucosal** transmission modes such as needle stick injury, injection drug abuse and sharing razors or tattooing or splashes of infected blood on eyes etc. are among the less effective modes of transmission.
- **Perinatal mode:** In the absence of any intervention, the risk of transmission from mother to fetus is about 20–40%.
  - Transmission may occur at any time during pregnancy and breast feeding but the risk is maximum during delivery.
  - Risk is maximum if mother is recently infected or has already developed AIDS.
- There is no evidence of HIV transmission by casual contact or kissing or insect bite.
- **Viral load** is maximum in blood, genital secretions, and CSF; variable in breast milk and saliva; zero to minimal in other body fluids or urine.

- Saliva may contain inhibitory substances like fibronectin and glycoproteins, which prevent transmission of the virus.

Receptor Attachment

- **Main receptor:** HIV enters into the target cells by binding its gp120 to the CD4 receptor on host cell surface. CD4 molecules are mainly expressed on helper T cells; and also on the surface of various other cells like monocytes, macrophages, Langerhans cells, astrocytes, keratinocytes and glial cells.
- **A second co-receptor** in addition to CD4 is necessary for fusion of HIV to gain entry into the host cell. Usually, the chemokine receptors act as co-receptors for HIV and act by binding to gp120. Examples include:
  - CXCR4 molecules present on T lymphocytes.
  - CCR5 molecules present on cells of macrophage lineage.
- **DC-SIGN**, a dendritic cell-specific lectin receptor present in skin and mucosal surfaces, can also bind to HIV-1 but does not mediate cell entry. Rather, it may facilitate transport of HIV by dendritic cells to lymphoid organs where HIV replicates further in T cells.

Mutation in CCR5 (delta 32 mutation)

This mutation results in blockade of HIV entry into the cells. It is observed among some lucky Europeans who are either:

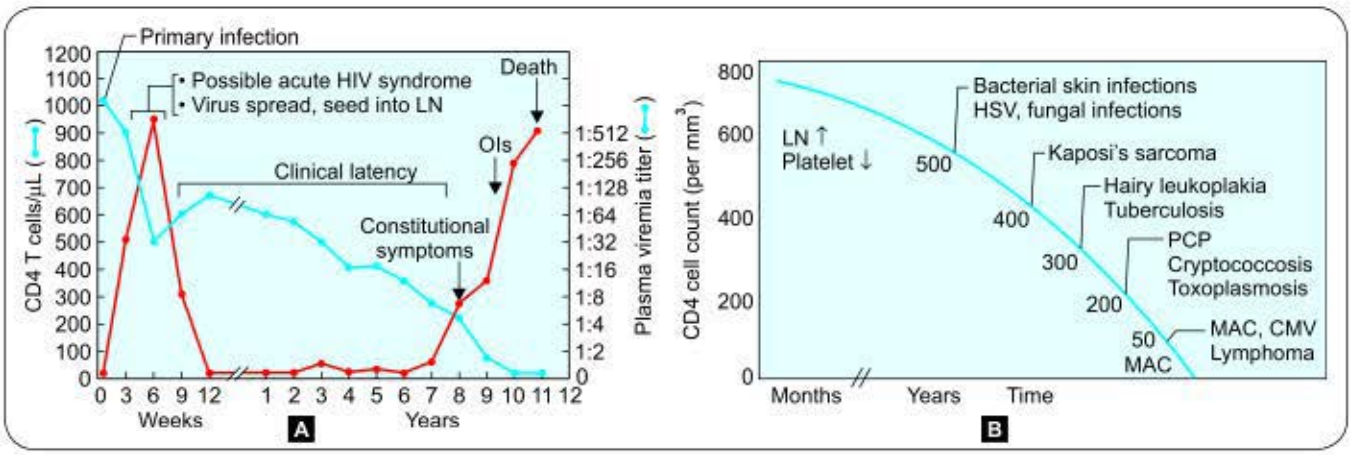
- **Completely resistant to HIV infection:** If they are homozygous for delta 32 mutation genes (seen in 1% of Northern Europeans, particularly Swedes) or
- **Susceptible but progress of AIDS is delayed:** If they are heterozygous for the same gene, seen in 10–15% of Europeans)

Replication (Fig. 41.7)

- **Fusion:** Following attachment of receptor and co-receptor to gp120, fusion of HIV to host cell takes place; mediated by the fusion protein gp41.
- **Penetration and uncoating:** After fusion, HIV nucleocapsid enters into the host cell cytoplasm, which is followed by uncoating and release of two copies of ssRNA and viral enzymes.
- **Reverse transcription:** Viral reverse transcriptase mediates transcription of its ssRNA into ssDNA so that DNA-RNA hybrid is formed. The RNA is degraded by viral endonuclease and ssDNA replicates to form ds DNA.
- Transcription of the DNA occurs to form some of the components of viral proteins.
- **Pre-integration complex:** The nucleoprotein complex formed, comprises of linear dsDNA, gag matrix protein, accessory vpr protein and viral integrase. This is called **pre-integration complex**, which is transported into the host cell nucleus.
- **Integration:** The viral dsDNA gets integrated into the host cell chromosome; mediated by viral integrase. The integrated virus is called as **provirus**.
- **Latency:** In the integrated state, HIV establishes a latent infection for variable period.
  However, HIV is different from other latent viruses as it is able to replicate even in latent state and is infectious to other neighbouring cells.

Immunopathogenesis

The natural course of HIV infection passes through the following stages (Fig. 48.2A).



Figs 48.2A and B: **A.** Natural course of HIV infection; **B.** Opportunistic infections associated with HIV infection and correlation with CD4 T cell counts

Abbreviations: PCP, *Pneumocystis* pneumonia; MAC, *Mycobacterium* avium complex; CMV, cytomegalovirus.; OIs, opportunistic infections.

Acute HIV Disease or Acute Retroviral Syndrome

Following infection, HIV is carried to the lymph nodes and other lymphoid tissues where further multiplication occurs inside the T cells.

- Initially, HIV destroys the infected T cells and spills over into blood stream to cause primary viremia (or acute mononucleosis-like syndrome) which coincides with an initial flu-like illness that occurs in many patients (50–75%) 3–6 weeks after the primary infection.
- There is a significant drop in the numbers of circulating CD4 T cells at this stage.

Asymptomatic Stage

Adequate immune response develops within 1 month in most of the patients.

- Both effective cell-mediated immune response (HIV specific CD8 T cells) and humoral response (HIV specific neutralizing antibodies) come into play.
- As a result, viremia drops down and CD4 T cell count becomes normal.
- It is important to note that this is a state of clinical latency, but **not microbiological latency**.
- The immune response cannot clear the infection completely, HIV-infected cells persist in the lymph nodes, and there is a high level of ongoing viral replication.
- This period of clinical latency is variable, may last for 10 years but ranges from few months to 30 years.
- However, once the latency is broken, the disease progresses rapidly and death usually occurs within 2 years if left untreated.

Persistent Generalized Lymphadenopathy (PGL)

As a result of HIV replication in lymph nodes, 25–30% of infected people who are otherwise asymptomatic, develop lymphadenopathy.

- PGL is defined as enlarged lymph nodes of more than 1 cm size in two or more non-contiguous sites that persist for at least 3 months.
- PGL must be distinguished from other causes of lymphadenopathies such as lymphoma.

Symptomatic HIV infection (AIDS Related Complex, ARC)

After variable period of clinical latency, the CD4 T cell level starts falling. Eventually patients develop constitutional symptoms such as:

- Unexplained diarrhea lasting for more than 1 month
- Weight loss more than 10% of body weight, fatigue malaise and night sweat.
- Mild opportunistic infections such as oral thrush.

AIDS

Gradually, the patient moves towards the advanced end stage of HIV infection called AIDS; characterized by:

- Rapid fall in CD4 T cell count (usually less than 200 cells/μl)
- High virus load
- Lymphoid tissue is totally destroyed and replaced by fibrous tissue.
- **Opportunistic infections** set in secondary to profound immune suppression. Depending on the CD4 T cell count, various infections occur (Fig. 48.2B).
- Development of neoplasia (e.g. CNS lymphoma)
- Development of direct HIV induced manifestations such as HIV encephalopathy

Clinical Diagnosis

Classification systems for HIV disease have been developed which are useful for tracking and monitoring the HIV epidemic, for providing clinicians and patients with important information about HIV disease stage and clinical management. Two such systems are currently in use worldwide:

1. **CDC classification system** (Centers for Disease Control and Prevention, revised 1993): This system classifies HIV infection into nine stages based on associated clinical conditions and CD4 T cell count of the patient.
2. **WHO clinical staging of HIV/AIDS for adults** (World Health Organization, revised 2007) is based only on the clinical conditions associated with the patient. For, resource poor countries like India, where facilities for the CD4 T cell count are not available widely, WHO clinical staging is more useful. It classifies HIV infection in adults and adolescents (>15 years) into four stages (Table 48.3).

TABLE 48.3: WHO clinical staging of HIV/AIDS for adults

WHO Clinical Staging of HIV/AIDS for adults (Revised,2007)
Clinical Stage 1
▪ Asymptomatic HIV infection ▪ Persistent generalized lymphadenopathy
Clinical Stage 2
▪ Unexplained moderate weight loss (< 10%) ▪ Recurrent respiratory tract infection (sinusitis, tonsillitis, otitis media, pharyngitis) ▪ Herpes zoster ▪ Angular cheilitis ▪ Recurrent oral ulcers ▪ Papular pruritic eruptions ▪ Seborrhoeic dermatitis ▪ Fungal nail infection

Contd...

Contd...

Clinical Stage 3

- Unexplained severe weight loss (>10%)
- Unexplained chronic diarrhea: >1month
- Unexplained persistent fever: 1month
- Oral candidiasis
- Oral hairy leukoplakia
- Pulmonary tuberculosis
- Severe bacterial infection
- Acute necrotizing ulcerative stomatitis, gingivitis, and periodontitis
- Unexplained anemia

Clinical Stage 4

- **HIV wasting syndrome (Slim disease):** Characterized by profound weight loss (>10%), chronic diarrhoea (> 1 month), prolonged unexplained fever (1 month)
- **Bacterial opportunistic infections:**
  - Recurrent severe bacterial infections
  - Extra pulmonary tuberculosis
  - Disseminated non-tubercular mycobacterial infection
  - Recurrent septicemia (including non-typhoidal salmonellosis)
- **Viral opportunistic infections:**
  - Chronic HSV infection
  - Progressive multifocal leukoencephalopathy
  - CMV (retinitis, or other organ infection excluding liver, spleen , and lymph node)
- **Fungal opportunistic infections:**
  - *Pneumocystis jirovecii* pneumonia
  - Esophageal candidiasis
  - Extrapulmonary cryptococcosis (meningitis)
  - Disseminated mycoses (histoplasmosis and coccidioidomycoses)
- **Parasitic opportunistic infections:**
  - *Toxoplasma* encephalitis
  - Chronic intestinal isosporiasis (>1 month)
  - Atypical disseminated leishmaniasis
  - Chronic intestinal cryptosporidiosis (>1 month)
- **Neoplasia:**
  - Kaposi's sarcoma
  - Invasive cervical cancer
  - Lymphoma (cerebral, B cell and non-Hodgkin)
- **Other conditions (direct HIV induced):**
  - HIV encephalopathy
  - Symptomatic HIV associated nephropathy or cardiomyopathy

Epidemiology

Global Situation

Since the discovery of AIDS epidemic, almost 78 million people have been infected and 39 million deaths occurred due to HIV worlwide.

- **Prevalence:** At the end of 2013, about 35 million people were living with HIV with a **global prevalence of 0.8%** in adults (Fig. 48.3).
- **Sub-Saharan Africa** remains the most severely affected region, with nearly one in every 20 adults living with HIV and accounting for nearly 71% of the people living with HIV worldwide.

HIV/AIDS Situation in India

By the end of 2011, the adult **HIV prevalence in India** was reported as **0.27%.**

- Number of PLHA (people living with HIV/AIDS) were over 20.8 lakh adults and 1.4 lakh children.
- **Andhra Pradesh** (undivided) was the worst affected state followed by Maharashtra and Karnataka in terms of PLHA.
- However, as far as prevalence (number of cases per 100 population) is concerned, Northeast states such as Nagaland, Mizoram and Manipur are worst affected.
- **Nagaland** probably is the only state to have higher prevalence rate (0.88%) than the global prevalence in 2012-13.

Reservoir

Infected people (both symptomatic as well as asymptomatic) are the only reservoir host; they harbor the virus for life.

High Risk Groups

High risk groups which commonly acquire infection are:

- Homosexuals and people with multiple sex partners, and prostitutes.
- Health care workers (via accidental needle pricks or blood splashes on eyes).
- Intravenous drug addicts
- Hemophiliacs and other recipients of blood or blood products
- People with other STDs (sexually transmitted diseases)

Opportunistic Infection

Globally including India, tuberculosis is the most common opportunistic infection that occurs in HIV infected people (Fig. 48.3).

- Common fungal infections are candidiasis (oral thrush) and *Pneumocystis jirovecii*
- Frequent viral infections are herpes simplex mucosal lesions and CMV retinitis
- Common parasitic infections are *Cryptosporidium parvum* diarrhea and *Toxoplasma* encephalitis

AIDS Control Organization

- **NACO:** National AIDS Control Organization (NACO) has been constituted to implement the HIV/AIDS

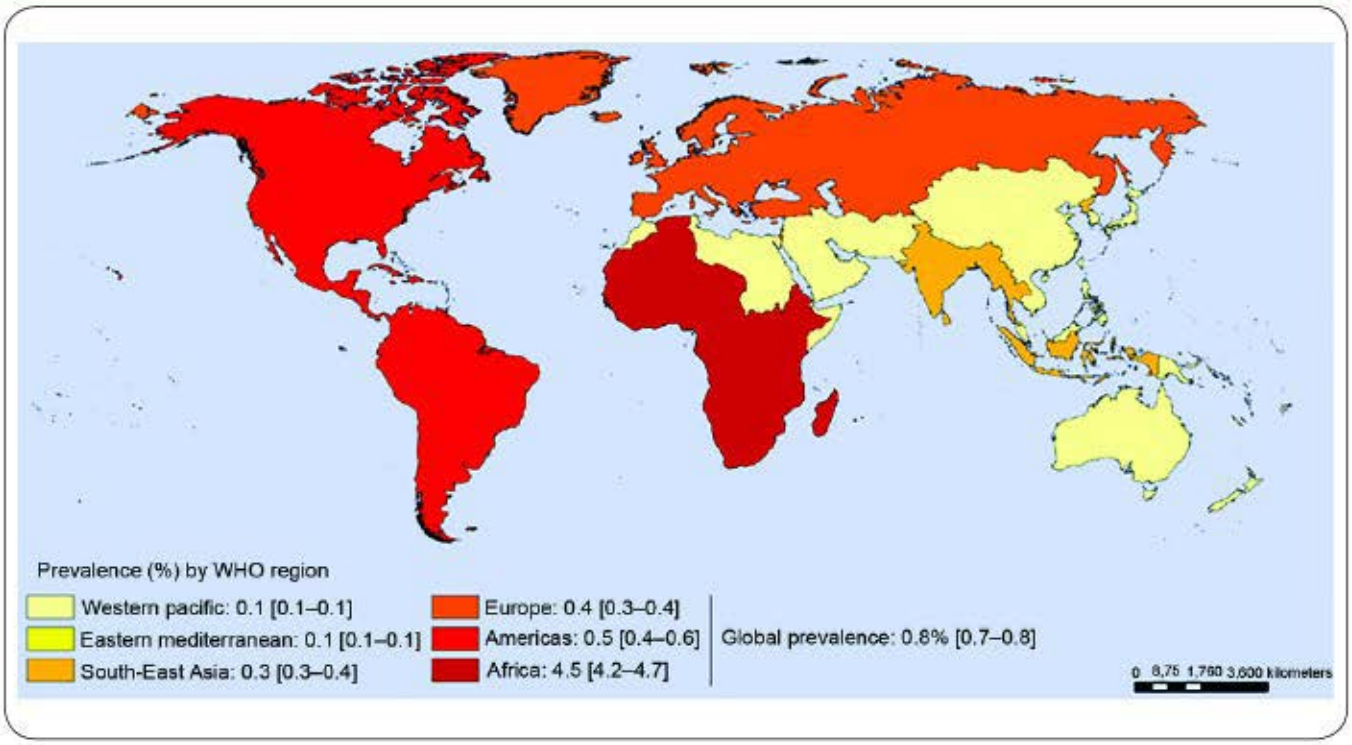


Fig. 48.3: Global HIV prevalence, 2013 (WHO)

Source: World Health Organization (*with permission*)

control programme in India. It provides single national plan within one monitoring system.

- **SACS:** State AIDS Prevention and Control Societies (SACS) are present in every state/union territory (35 numbers). They implement NACO programme at state level.

Kinetics of Immune Response

An understanding of the kinetics of host immune response following infection is needed before we discuss the laboratory diagnosis; so as to understand the optimal usage of various tests during different stages of HIV disease.

- **Viremia:** Soon following the entry of the virus into the body, there occurs a transient period of high level viremia and p24 antigenemia. However, the levels of these components fall down with concomitant immune response.
- **Humoral response** is evidenced by formation of antibodies of different classes (IgM, IgA, IgG) against different **structural proteins** (*gag*: p15, p17, p24, p55; *env*: gp 41, gp 120, gp 160; and *pol*: p31, p51 and p66), **regulatory proteins** (nef, rev, tat) and **accessory proteins** (vif, vpu and vpr).
- All **structural components are strongly immunogenic** and induce formation of antibodies; whereas, immunogenicity of regulatory and accessory proteins is variable.
- **Window period:** Following infection, antibodies appear in serum only after a period of interval, which is called window period. This is about 3 to 12 weeks.
- **The antibodies to *gag* protein** (p24 and p55) usually appear first, though antibodies to *env* proteins and *pol* proteins may also be produced simultaneously.
- As infection progresses to AIDS, antibody to p24 usually declines as p24 antigen levels rise concomitant with progression of disease to AIDS. However, antibodies to *env* proteins persist throughout the infection.
- **Anti-HIV antibodies:** Among the antibodies (IgA, IgM and IgG) appear, only IgG response is consistent and long lasting. Most currently available assays detect IgG antibodies.
  - IgM response appears earlier than IgG but sensitivity is low and is detectable for a short period. However, it is valuable for identifying early seroconversion (2–11 days) particularly following needle stick injury and infection in newborn.
  - Detection of IgA is useful in specimens such as sero mucous secretions (saliva, colostrum, genitourinary secretion, etc.) and in newborn.

LABORATORY DIAGNOSIS — HIV Infection

Specific Tests for HIV Infection

- **Screening tests** (ERS) (antibody detection):
  - ELISA (takes 2–3 hours)
  - Rapid/Simple test (takes < 30 minutes)
- **Supplemental tests** (antibody detection):
  - Western blot assay
  - Immunofluorescence assay
  - Radio-immuno-precipitation assay (RIPA)
  - Line immunoassay (LIA)
- **Confirmatory tests**
  - p 24 antigen detection
  - Viral culture – by Co-cultivation technique
  - HIV RNA (best confirmatory method)
    - Reverse transcriptase PCR (RT-PCR)
    - Branched DNA assay
    - NASBA (Nucleic acid sequence based amplification)
    - Real time RT-PCR- for estimating viral load
  - HIV DNA detection- Useful for diagnosis of paediatric HIV

Non-specific Immunological Methods

- Low CD4 T cell count
- Hypergammaglobulinemia
  - Neopterin
  - β2-macroglobulin
- Altered CD4 : CD8 T cell ratio

Laboratory Diagnosis

Diagnosis of HIV/AIDS is not like other infectious diseases. A number of moral, ethical, legal and psychosocial issues are associated with a positive HIV status. Disease is life long, outcome is invariably fatal,no cure or vaccine is available so far, and in majority, the transmission is through sexual contact. Hence, individuals known to be HIV infected are stigmatized and develop fear of being discriminated and socially out casted. Therefore, the following care should be taken **(3Cs)** while performing the test for HIV.

- **Consent** in written format should be taken before the test is done. Patient should be explained about the nature of the test being performed.
- **Confidentiality** of a positive test result is must. Patient name or the word "HIV positive" should not be written on the report form.
- **Counselling** should be provided to motivate the individual to tell the spouse/family and induce behavioural change.

Antibody Detection

Detection of anti-HIV antibodies is the mainstay of diagnosis of HIV. Tests to detect specific HIV antibodies can be classified into:

Screening Assays

Screening assays usually take less time (2–3 hours for ELISA, less than 30 minutes for rapid/simple tests)

- **High sensitivity:** They must detect all positive sera; even if some false positive results may occur.
- **Should be confirmed:** Results of a screening test should never be used as the final interpretation of HIV status as false positive results or technical errors can occur. It is always subjected to confirmatory tests.
- Antigens used in most of the screening tests are:
  - HIV-1 specific (p24, gp 120, gp160, gp41)
  - HIV-2 specific gp36
- They detect HIV-1 and 2 either separately or together.

ELISA (Enzyme-linked Immunosorbant Assay)

ELISA is the most commonly performed screening test at blood banks and tertiary care sites. It is easy to perform, adaptable to large number of samples. It is sensitive, specific, and cost effective.

Types

Different types of ELISA kits (based on type of HIV antigen used) are available commercially:

- **1st generation ELISA:** Uses crude preparation of HIV antigens. It yields more false positive results, hence not in use now.
- **2nd generation ELISA:** Uses recombinant antigens of HIV
- **3rd generation ELISA:** Uses synthetic oligopeptide antigens of HIV
- **4th generation ELISA:** Detects both HIV antibodies and antigen (p24) by using combination of recombinant/ synthetic peptides as well as monoclonal antibodies respectively.

Principle of ELISA

Various ELISA formats are in use depending on the different principles such as:

- Indirect ELISA
- Competitive ELISA
- Sandwich ELISA

Rapid/Simple Test

These assays have been developed for ease of performance and quick results. They generally require less than 30 minutes to perform and do not require special equipments. They are the most commonly used tests in India. They work on various principles such as:

- Dot blot assays (or Immunoconcentration or flow through method)
- Immunochromatography (or ICT, lateral flow assay)
- Particle agglutination assays (using latex, gelatin, RBCs)
- Dip stick/Comb tests (ELISA based assays)

Supplemental Tests

These assays are highly specific antibody detection methods; hence used for validation of positive results of

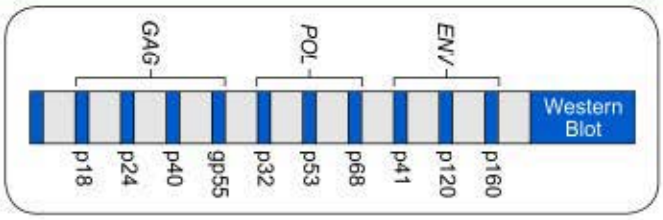

Fig. 48.4: HIV Western blot test strip

screening tests. They are expensive, labor intensive, need expertise to interpret, and may also give unequivocal/indeterminate results.

Western Blot

It is the most commonly used supplementary test available and is also recommended by NACO.

- It works on the principle of immunoblot technique (described in Chapter 12).
- It detects individual antibodies in serum separately against various antigenic fragments of HIV such as (Fig. 48.4).
  - Antibody to *gag* gene products (gp55, gp40, gp24, gp18)
  - Antibody to *pol* gene products (gp68, gp53, gp32)
  - Antibody to *env* gene products (gp 120, gp160, gp41)
- The antigen antibody complexes appear as distinct bands on nitrocellulose strip.
- Reactive results are interpreted as per
  - WHO criteria i.e. presence of at least two envelope bands (out of gp120, gp160 or gp41) with or without gag or pol bands
  - CDC criteria-presence of any two out of p24, gp 120, gp160, gp41 bands.

Detection of p24 Core Antigen

The p24 antigen becomes detectable after 1 to 2 weeks (mean 12 days) of infection and lasts for 3–4 weeks thereafter. Again, it is elevated during the late advanced stage of AIDS.

- **It is less sensitive** (~30%) because once the antibody is formed, it binds to the p24 protein and the antigen-antibody complex gets eliminated from blood.
- Recently, antigen dissociation assay has been developed that involves pre-treatment of serum to an agent, that liberates p24 antigen from the immunocomplexes. This has shown better sensitivity.
- Uses of p24 antigen detection test:
  - For confirmation of diagnosis of HIV/AIDS
  - Diagnosis of HIV during window period
  - To diagnose late stage of HIV/AIDS (immune collapse) or CNS disease
  - Diagnosis of HIV in infants (not reliable)
  - Monitoring the progress of HIV infection
  - To resolve equivocal western blot results

Viral RNA Detection

Detection of viral RNA is the **"gold standard"** method for confirmation of HIV diagnosis. Various formats available are:

- Reverse transcriptase polymerase chain reaction (RT-PCR)
- Branched DNA assay
- NASBA: Nucleic acid sequence based amplification
- Real time RT-PCR: For estimating viral load

Apart from the routine diagnosis of HIV, RNA detection has several other uses such as:

- It is the **most sensitive** and **specific** method, detects even few copies of viral RNA and is the best method **for confirmation** of HIV.
- It is the best tool for diagnosis of HIV during **window period**, detects HIV earlier than all available methods (12 days post exposure).
- **Viral load monitoring:** Real time RT-PCR can quantify the viral load and is the most appropriate tool for monitoring the response to antiretroviral therapy.
- **Typing:** RT-PCR can successfully differentiate between HIV-1 and HIV-2 infections and can detect the specific genotype or subtype.
- Detection of **drug resistance** genes

DNA PCR

PCR detecting proviral DNA is extremely useful for diagnosis of paediatric HIV and to differentiate latent HIV infection from active viral transcription. It is also useful during the window period, viral load estimation (real time PCR) and detection of genotypes.

Isolation of the Virus from Blood or Tissues

Isolation is time consuming, expensive, takes longer time (6 weeks or more) and not sensitive. This is due to the lower number of available cells cultured and paucity of infected cells in the sample that are present. Two methods are being used for virus isolation:

1. **In the direct method**, peripheral blood mononuclear cells (PBMCs) from the patient are cultured *in vitro* in presence of mitogen phytohemagglutinin (PHA).
2. **In the co-cultivation method**, PBMCs from heterologous HIV uninfected donor are stimulated with PHA, and after 48–72 hours, the stimulated cells are cultured along with the PBMCs from the patient.
   - Viral growth in the culture supernatant is detected either by demonstration of the presence of p24 antigen or reverse transcriptase enzyme or syncytia formation in the infected cells or immunofluorescence assay to detect the viral antigens in the infected cells.
   - HIV cultivation is predominantly a research tool and is available only in a few reference

laboratories, as it requires at least level-2 containment facility and high degree of expertise.

Non-specific/Immunological Tests

- **CD4 T cell count:** Measurement of CD4 T cell count is carried out by flow cytometry method. It is useful in:
  - Assessing the risk of opportunistic infections (Fig. 48.2B).
  - Initiation of antiretroviral therapy—if CD4 T cell count falls below 350/mm^3.
  - Monitoring the response to antiretroviral therapy.
- **Abnormal proteins** such as neopterin, beta 2-microglobulin and soluble IL-2 receptor are produced by peripheral blood mononuclear cells; stimulated by interferon-gamma or IL-2 which in turn are produced by HIV activated T_H1 cells.

NACO Strategy for HIV Diagnosis

For the resource poor countries, it is impracticable to confirm the result of HIV screening tests by PCR or western blot as these assays are expensive and available only at limited centres.

NACO (National AIDS Control Organization, India) has formulated a strategic plan for HIV diagnosis. The guidelines are as follows:

- Depending on the situation/condition, for which the test is done, the positive result of the first screening test should be either considered as such or confirmed by another one or two screening tests.
- The first screening test should be highly sensitive whereas the second and third screening tests should have high specificity.
- The three screening tests should use different principles or different antigens. The same kit should not be used again.
- Supplemental or confirmatory tests should be used only when the screening test(s) results are equivocal/intermediate.

There are four NACO Strategic Plans/Algorithms (Fig. 48.5):

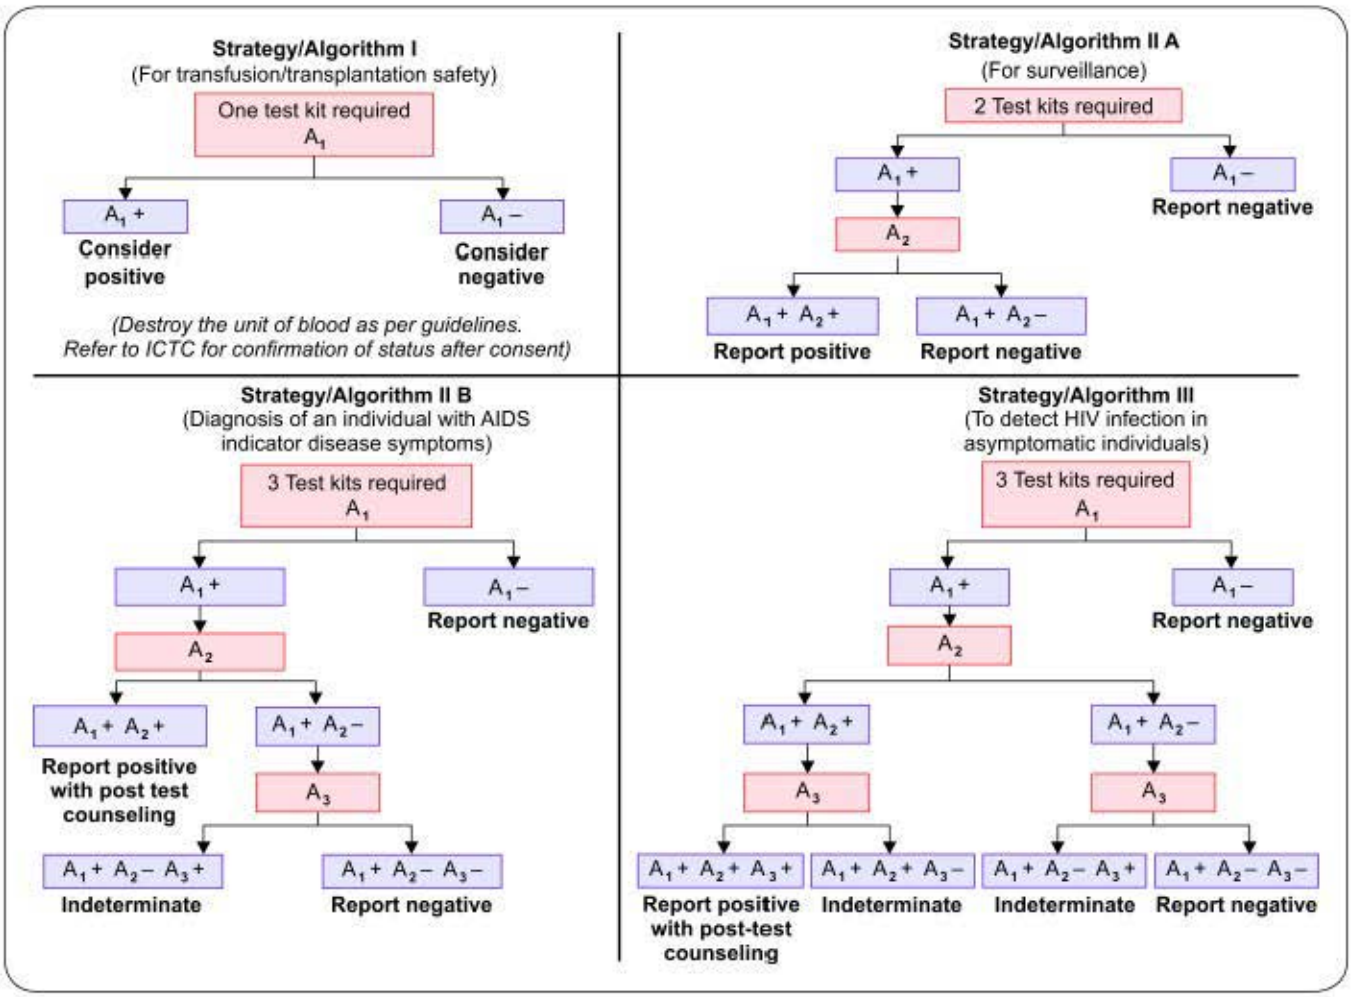

Fig. 48.5: Algorithms for diagnosing HIV infection

1. **Strategy I:**
   - **Purpose:** It is done for transfusion and transplantation safety; i.e. for the screening for the blood donors in blood banks.
   - Only one test should be done. If found reactive, then the unit of blood is destroyed.
2. **Strategy IIa:**
   - **Purpose:** It is done for seroprevalence or epidemiological purpose.
   - **Two tests format:** Positive results of the first test should be confirmed by a second test. If the second test is negative, then it is reported as negative.
3. **Strategy IIb:**
   - **Purpose:** It is followed for the diagnosis of HIV/AIDS in symptomatic patients.
   - Positive results of first test should be confirmed by a second test. If the second test is negative, then a third test is done for confirmation.
4. **Strategy III:**
   - **Purpose:** It is done for the diagnosis of asymptomatic HIV patients, antenatal screening and screening of patients awaiting surgeries.
   - **Three tests format:** All positive results in first test should be confirmed by second and third test. Positive report is sent only if all three tests are found reactive.
   - For indeterminate results of strategy IIB and III, (i.e. first test positive but second or third test negative), the repeat test is done after 2–4 weeks and the sample should be sent to reference centre for confirmation by western blot or RT-PCR.

Prognosis/monitoring of HIV

Various tools available for monitoring the response to antiretroviral therapy include:

- **CD4 T cell count:** Most commonly used
- **HIV RNA load:** Most consistent and best tool at present
- p24 antigen detection
- Neopterin and β2 macroglobulin level

Note: Viral antibody levels are inconsistent and variable during late stage due to immune collapse; hence not reliable for prognosis.

Diagnosis of Pediatric HIV

The routine screening methods (ELISA or rapid/simple tests) detect IgG antibodies.

- They cannot differentiate between baby's IgG or maternally transferred IgG, hence cannot be used for the diagnosis of paediatric HIV.
- As all maternal antibodies would disappear by 18 months; therefore IgG assays can be performed after 18 months of birth.

The recommended methods for diagnosis of paediatric HIV include:

- HIV DNA detection-most recommended
- HIV RNA detection
- p24 antigen detection
- IgG ELISA only after 18 months of age

Diagnosis of HIV in Window Period

Definition: Window period refers to the initial time interval between the exposure and appearance of detectable levels of antibodies in the serum.

- The antibodies appear in blood within 2–8 weeks after infection but usually become detectable after 3 weeks to 12 weeks with the assays available presently. It can be as low as 22 days; when third generation antibody detection kits with high sensitivity are used.
- p24 antigen detection (30% sensitive): It can be detected by 1–2 weeks (average 16th day)
- HIV RNA detection (by RT-PCR) is the best method—it detects HIV RNA as early as 12th day.

TREATMENT HIV

Antiretroviral Therapy (ART)

Antiretroviral therapy (ART) denotes the approved drugs used for the treatment of HIV/AIDS (Table 48.4). The drugs do not kill all the viruses or cure the disease. However, they have the following goals:

- **Clinical goals:** Prolongation of life, improvement in quality of life and stoppage of the progression of HIV infection to AIDS.
- **Virological goals:** Greatest possible reduction in the viral load as long as possible.
- **Immunological goals:** Immune reconstitution; both quantitative and qualitative improvement.
- **Transmission goal:** Reduction of HIV transmission in individuals.

Indication to start ART

According to NACO guidelines, the initiation of ART should be based on CD4 T cell count and WHO clinical staging.

- **Clinical Stage I and II:** Start ART if CD4 T cell count < 350 cells/mm^3
- **Clinical Stage III and IV:** Start ART irrespective of CD4 T cell count

Other indications include

- **For HIV and TB co-infected patients:** Start ART irrespective of CD4 T cell count and type of tuberculosis (Start anti-tubercular drug first, initiate ART after 2 weeks when TB drugs are well tolerated)
- HIV and HBV/HCV co-infection
- HIV infected pregnant women
- Patients with HIV nephropathy

Principles for Selecting the First-line Regimen

Highly active antiretroviral therapy (HAART) is referred to the use of combination of **at least three** antiretroviral drugs to maximally suppress the HIV and stop the progression of the disease. Monotherapy with single drug is contraindicated.

NACO guideline: It recommends to include three drugs (2NRTIs + 1NNRTI) universally in all first line regimens (Table 48.5) which is as follows:

- Choose Lamivudine in all regimens

TABLE 48.4: Antiretroviral drugs

NRTI (Nucleoside reverse transcriptase inhibitors)	NNRTI (Non-nucleoside reverse transcriptase inhibitors)	PI (Protease inhibitors)	Fusion inhibitors
Zidovudine	Nevirapine	Saquinavir	Enfuvirtide
Stavudine	Efavirenz	Ritonavir	**Integrase inhibitors**
Lamivudine	Delavirdine	Nelfinavir	Raltegravir
Didanosine		Amprenavir	**CCR5 receptor inhibitor**
Zalcitabine		Indinavir	Maraviroc
Abacavir		Lopinavir	
Emtricitabine		Ritonavir	
		Fosamprenavir	
NtRTI (Nucleotide reverse transcriptase inhibitor)		Atazanavir	
Tenofovir		Tipranavir	

TABLE 48.5: NACO recommended first-line ART Regimens

Preferred regimen
Lamivudine + Zidovudine + Nevirapine
Alternate regimens
Lamivudine + Zidovudine + Efavirenz
Lamivudine + Stavudine + Efavirenz
Lamivudine + Stavudine +Nevirapine

- Choose another NRTI in addition to Lamivudine (such as Zidovudine)
- Choose one NNRTI (Nevirapine or Efavirenz)

Opportunistic Infections (OIs) should be adequately treated before starting ART.

Problems Pertaining to use of ART

Although early start of ART can reduce the risk of disease progression, there are many other factors that pose deleterious effects on quality of life.

- Toxicity and adverse side effects of ARTs, especially lipid abnormalities and drug interactions
- High cost of the regimen
- Risk of development of drug resistance and dissemination of resistant virus
- Limited therapeutic options
- **IRIS (Immune reconstitution inflammatory syndrome):** It can occur (IRIS) occurs in some cases of AIDS during the recovery phase following the start of ART. As the viral load decreases, the immune system begins to recover, which results in an exaggerated immune response to a previously acquired opportunistic infection causing an overwhelming inflammatory response that paradoxically makes the symptoms of infection worse.

Post-exposure Prophylaxis

Post-exposure prophylaxis (PEP) is short-term antiretroviral treatment (ART) to reduce the likelihood of HIV infection after potential occupational exposure, either by needle or sharp pricks or mucocutaneous exposure. Within the hospital, PEP should be provided as part of a comprehensive universal precautions package that reduces hospital staff exposure to infectious hazards at work.

Guidelines for Post Exposure Prophylaxis

Initiation of PEP depends on the type and severity of exposure, and the HIV status of the source (Table 48.6)

- PEP must be initiated as soon as possible, preferably within **2 hours** but not later than 72 hours.
- The **risk of transmission** of HIV following needle stick injury is about 0.3% (HCV 3–10% and HBV 6–30%) and infected blood splash to mucus membrane of eye, nose, and mouth is about 0.09%.
- However, if started soon after exposure, PEP can reduce the risk of HIV infection by more than 80%.
- **Two regimens** of ART are available; basic and expanded regimen. ART drugs for PEP should be taken for 28 days.
- **Baseline HIV test** of the health care worker should be done at the time of exposure and if found negative then, to be repeated at 6 weeks, 3 months, 6 months and 1 year following exposure.

NACO Guidelines to Prevent Neonatal HIV

Recommended regimen: Single dose of **nevirapine** is administered to the mother during labor and to the baby within 72 hours after birth.

TABLE 48.6: NACO Guidelines for post-exposure prophylaxis

Exposure code	HIV status code	Regimen
1	1	Not required
1	2	Basic
2	1	Basic
2	2	Expanded
3	1 or 2	Expanded
2 or 3	Unknown	Basic*

Source material: Blood, body fluids or other potentially infectious material (CSF, synovial, pleural, pericardial and amniotic fluid, and pus) or an instrument contaminated with any of these substances

Exposure code:

- **EC1 (Mild exposure):** Mucous membrane/non-intact skin exposure with small volumes, or less duration.
- **EC2 (Moderate exposure):**
  - Mucous membrane/non-intact skin with large volumes/ splashes for several minutes or more duration or
  - Percutaneous superficial exposure with solid needle or superficial scratch.
- **EC3 (Severe exposure):** Percutaneous exposure with:
  - Large volume,
  - By hollow needle, deep puncture,
  - Visible blood on device or
  - Needle used in patient's artery or vein.

Source HIV Status Code (SC):

- **SC 1**-HIV positive, asymptomatic, CD4 T cell count high, low viral load.
- **SC 2**-HIV positive, symptomatic (advanced AIDS or primary HIV infection), CD4 T cell count low, high viral load
- **SC Unknown:** Source unknown

Basic regimen (for 4 weeks): 2 drugs (NRTIs)

- Zidovudine (300 mg twice a day) and
- Lamivudine (300 mg twice a day)

Expanded regimen (for 4 weeks): 3 drugs (2 NRTIs +1 PI)

Basic regimen Plus

- Indinavir (800 mg thrice a day) or
- Nelfinavir (750 mg thrice a day) for 4 weeks

*In case of an unknown source, and the setting where the exposure occurred suggests a possible risk for HIV exposure, PEP basic regimen can be considered.

HIV Vaccine Strategies

Hurdles to Jump

After 34 years of discovery of HIV/AIDS, still medical research failed to invent an effective approved vaccine. This attributes to various factors:

- High mutability of the virus is the single most important factor.
- Concept of live attenuated or even killed vaccine is impracticable due to possible risk of reactivation.
- Long latent period between exposure and appearance of symptoms.

Contd...

Contd...

- Lack of ideal small animal models for studying HIV infection
- Ethical issue: Difficulty tto get human volunteers for HIV vaccine trial
- Natural immunity fails to clear HIV as it targets cells of the immune system
- As HIV is a retrovirus: Viral genome soon gets integrated into the host genome. Hence, it provides short window of opportunity to control

Approaches and Trials

The researchers have explored a number of strategies and based on which more than 40 vaccine trials have been conducted in several countries so far.

- **Recombinant sub-unit vaccines** (e.g. enveloped proteins): e.g. **Vax Gen** trial used gp120 protein
- **Modified envelope vaccines**
- **Peptide vaccines:** ANRS VAC 18 trial used LIPO-5, which contains five lipopeptides from the *gag*, *nef* and *pol* genes corresponding to more than 50 epitopes.
- **DNA vaccines:** These are the small pieces of DNA containing genes from HIV, grown in bacteria. After injecting into the host, the HIV genes get integrated with host cell genome and start transcribing the proteins against which host mounts an immune response. Example include **HVTN 505** vaccine trial (DNA/recombinant Adenovirus type 5/ HIV-1)
- **Recombinant vector vaccines:** Most of the current approaches for HIV vaccine trials are based on inserting subunit immunogens of HIV into vaccine vectors (a non-pathogenic viral or bacterial agent) such as:
  - Adenovirus type 5: Used in **STEP** vaccine trial
  - Canarypoxvirus inserted with gp120 gene (used in RV144 trial)
  - Adeno-associated virus (used in **tgAAC09** vaccine trial, in India).
  - Modified Vaccinia ankara (MVA) virus: This virus was used in vaccine trial conducted by International AIDS vaccine initiative (IAVI) in collaboration with NACO, India.

Prime Boost Strategy

Most studies use a combination of the above types of vaccines in the form of '**prime and boost**' vaccines, in which two or more different vaccines are used to broaden or intensify immune responses. Examples include a vector virus is used to prime a T-cell response; along with a subunit (peptide) booster or DNA vaccine booster is used to produce antibodies.

In spite of intense research, effort and finance involved, none of the trails has been approved for human use till now.

HUMAN T CELL LYMPHOTROPIC VIRUS (HTLV)

Human T cell lymphotropic virus (HTLV) belongs to the family Retroviridae, under the genus *Deltaretrovirus*. Two important members are HTLV-I and HTLV-II.

Human T cell lymphotropic Virus-I (HTLV-I)

Pathogenesis

- **Transmission** of HTLV-I occurs by—(1) from mother to child especially via breast milk (most common); (2) sexual (men to women), (3) infected blood
- **Target cells:** Like HIV, HTLV-I has tropism for CD4 T cells; but occasionally also infect CD8 T cells, dendritic cells and B cells.
- **Virus entry** into the host cells is mediated through interaction of the envelope glycoprotein with the host cell receptor **GLUT1** (Human glucose transporter protein-1).
- **Following entry**, it replicates inside the T cells similar to that of HIV. Viral RNA is reverse transcribed to DNA, which integrates into host cell DNA. Once integrated, HTLV-I continues to exist only as a provirus which can spread from cell-to-cell. Unlike HIV, there is no free virions of HTLV-I circulated in blood.
- HTLV-I expresses a unique gene called *Tax* gene which acts as a transactivator, causing the transcription of viral proteins in the long terminal repeat that are essential for replication.
- ***Tax* gene has oncogenic potential:**
  - It modulates several signalling pathways such as NF-κB and modulate many human growth regulatory genes.
  - It promotes the host cell growth cycle by accelerating the transition between G1 and S phase.
  - DNA repair pathways (base excision repair and nucleotide excision repair) are affected, leads to DNA mutation.

Epidemiology

- **Distribution:** HTLV-I is endemic in certain parts of Japan (10% prevalence) and the Caribbean basin of Africa but it is also found sporadically elsewhere.
- **Genotypes:** It has 7 genotypes; type-A is the most common, others are found only in central Africa except type-C which is endemic only in Asia (Papua New Guinea).

Clinical Manifestations

HTLV-I is a potential human oncogenic virus. It is associated with the following conditions.

- Adult T cell leukemia/lymphoma—it ranges from an indolent and slowly progressive type to a very aggressive type.
- Cutaneous T-cell lymphoma
- Tropical spastic paraparesis
- Auto immune manifestations such as inflammatory disease, uveitis and arthropathies.

Human T cell lymphotropic virus-II (HTLV-II)

HTLV-II is endemic in certain native American tribes and in Africa. Transmission and replication of HTLV-II is similar to that of HTLV-1. However, its pathogenic potential is uncertain.

EXPECTED QUESTIONS

I. Essay:

1. A 25-year-old male with history of multiple sex partners is admitted with complaints of unexplained fever, progressive loss of weight, persistent diarrhea and generalized lymphadenopathy for the past 6 months.
   a. What is the most probable diagnosis?
   b. Draw a labelled diagram of the morphology of the causative agent of this condition?
   c. Discuss the pathogenesis and laboratory diagnosis of the above condition?

II. Write short notes on:

1. Replication of HIV
2. Epidemiology of HIV/AIDS
3. NACO Strategies

III. Multiple Choice Questions (MCQs):

1. The gene coding for core of HIV is:
a. *gag* b. *env*
c. *pol* d. *tat*

2. During the window period of patient with AIDS, best diagnostic test is:
a. ELISA b. Western Blot
c. Rapid test d. RT-PCR

3. Best indicator of HIV prognosis:
a. CD4 T cell count b. CD8 T cell count
c. HIV RNA d. ELISA

4. Most effective mode of transmission of HIV:
a. Sexual b. Blood product
c. Needle/syringe d. Mother to fetus

5. Most common malignancy in AIDS is:
a. Kaposi sarcoma b. B-cell lymphoma
c. Leukemia d. Burkitt's lymphoma

Answers

1. a **2.** d **3.** c **4.** b **5.** a

CHAPTER 49

Miscellaneous RNA Viruses

Chapter Preview: Covers the following RNA viruses:

- Rodent borne viruses
  - Hantaviruses
  - Arenaviruses
- Filoviruses
  - Ebola virus
  - Marburg virus
- Coronaviruses
- Slow viruses
- Rotavirus and other agents of viral gastroenteritis
- Bornavirus

RODENT BORNE VIRUSES

Rodent-borne viruses or roboviruses are transmitted from rodents to man by contact with infected body fluids or excretions. They are maintained in nature by transmission from rodent to rodent without participation of arthropod vectors.

Major rodent-borne viruses include:

- **Hantaviruses:** They cause two categories of manifestations:
  - Hemorrhagic fever with renal syndrome is caused by several members of hantaviruses such as Hantaan virus, Dobrava virus, Puumala virus and Seoul virus.
  - Hantavirus pulmonary syndrome is caused by another member, Sin Nombre virus.
- **Arenaviruses:**
  - New world viruses: Examples include Junin, Machupo, Guanarito and Sabia viruses. They cause South American hemorrhagic fever.
  - Old world viruses: Examples include Lassa viruses and lymphocytic choriomeningitis viruses.

Hantaviruses

Genus *Hantavirus* belongs to the family Bunyaviridae.

- They are spherical, enveloped viruses; contain triple-segmented, negative-sense ssRNA.
- They cause two fatal human diseases—hemorrhagic fever with renal syndrome and hantavirus pulmonary syndrome
- Worldwide, about 1–2 Lakh cases of hantavirus infections occur annually.
- **Reservoir:** Rodents are the reservoir of infection, but they do not suffer from the disease. They harbor the virus lifelong and transmit to other rodents horizontally.
- **Transmission** to humans occurs by inhaling aerosols generated from rodent excreta (urine, feces and saliva).

1. Hemorrhagic Fever with Renal Syndrome (HFRS)

It is an acute viral infection, characterized by:

- **Interstitial nephritis** that leads to renal failure in severe forms of the disease
- Hemorrhagic fever and shock. Several hantaviruses can cause this condition—
- Hantaan and Dobrava viruses cause the severe form of HFRS in Asia, particularly in China, Russia, and Korea, and in Europe(Balkans)
- Seoul virus causes a less severe form of HFRS throughout Eurasia.
- Puumala virus causes a mild form of nephritis called nephropathiaepidemica, prevalent in Scandinavia.

2. Hantavirus Pulmonary Syndrome

Sin Nombre virus is the agent of hantavirus pulmonary syndrome which is prevalent in America.

- It has caused an outbreak of severe respiratory illness which occurred in the United States in 1993.
- The deer mouse (*Peromyscus maniculatus*) is the primary rodent reservoir.

Laboratory Diagnosis

The laboratory diagnosis tools for hantavirus infections include:

- Viral RNA detection by RT-PCR
- Viral antigen detection in fixed tissues by immunohistochemistry
- Specific antibodies can be detected by ELISA using recombinant proteins. Detection of IgM or four fold rise in IgG is considered significant.

- Isolation of hantaviruses is difficult and requires specific biosafety cabinets.

TREATMENT **Hantaviruses**

There is no specific antiviral therapy for hantaviral diseases. Only supportive symptomatic treatment is given such as maintenance of airways and renal function.

Preventive Measures

Preventive measures are based on rodent control and avoidance of contact with rodents and rodent droppings.

Arenaviruses

Arenaviruses are pleomorphic, 50–300 nm in size, enveloped with large, **club-shaped peplomers** and contain a segmented ssRNA **(two segments)**.

- **Reservoir:** Rodents are the reservoir and each virus is associated with a single rodent species.
- **Transmission:** Humans are infected by direct contact or inhalation of aerosols generated from rodent excreta.
- **Classification:** Based on RNA sequence differences and geographical distribution, arenaviruses are classified into old world and new world viruses (Table 49.1).

Old World Viruses

- **Lassa fever virus** is endemic in western African countries.
  - Reservoir is house rat (*Mastomys natalensis*)
  - Human infection is manifested as hemorrhagic fever, pneumonia, cardiac and renal damage. Permanent deafness is a common complication, occurs in 25% of cases following recovery.
  - Pregnancy: Both fetal death (90%) and maternal deaths (30%) can occur especially in third trimester.
  - Treatment: Ribavirin is the drug of choice for Lassa fever.
- **Lymphocytic choriomeningitis virus** (LCM) is widespread in Europe and the Americas.
  - Reservoir is the wild house mouse, *Mus musculus*
  - Human infection: LCM virus causes aseptic meningitis or a mild systemic influenza-like illness in humans. Rarely, encephalomyelitis or fatal systemic disease may develop. Infection is severe in immunocompromised people.
  - *Fetus:* Vertical transmission occurs early in pregnancy following which it can cause hydrocephalus, blindness or even fetal death.

Laboratory diagnosis of both Lassa and LCM virus includes:

- ELISA detecting serum IgM and IgG antibodies
- Immunohistochemical staining of tissues for viral antigen detection
- RT-PCR for detecting viral RNA
- Viral culture using Vero cells

New World Viruses

They cause South American hemorrhagic fever. Various examples include:

- **Junin virus** causes Argentine hemorrhagic fever affecting agricultural workers. In Argentina, more than 18,000 cases were reported during 1958–1980 and many cases still occur thereafter with a mortality rate of 15–20%. Rodent, *Calomys musculinus* is the reservoir.
- **Machupovirus** causes Bolivian hemorrhagic fever. About 2000–3000 persons were affected, with a case-fatality rate of 20%. Rodent, *Calomys callosus* is the reservoir.
- **Guanarito virus** is the agent of Venezuelan hemorrhagic fever.
- **Sabia virus** causes hemorrhagic fever in Brazil
- **Whitewater Arroyo viruses** cause hemorrhagic fever in Southwestern USA.

TABLE 49.1: Rodent-borne viral infections

Virus	Disease	Vector	Distribution
Old world complex			
Lassa virus	Lassa fever	Mouse (*Mastomys natalensis*)	West Africa
LCM virus	Lymphocytic choriomeningitis	House mouse (*Mus musculus*)	Worldwide
New world complex			
Junin virus	Argentine hemorrhagic fever	Drylands vesper mouse (*Calomys musculinus*)	Argentina
Machupo virus	Bolivian hemorrhagic fever	Large vesper mouse (*Calomys callosus*)	Bolivia
Guanarito virus	Venezuelan hemorrhagic fever	Short-tailed Cane mouse (*Zygodontomys brevicauda*)	Venezuela
Sabia virus	Brazilian hemorrhagic fever	Unknown	Brazil
Whitewater Arroyo virus	Hemorrhagic fever	Woodrat (*Neotoma*)	Southwestern USA

FILOVIRUSES

Family Filoviridae contains two antigenically distinct genera—*Ebolavirus* and *Marburgvirus*; both cause African hemorrhagic fever.

- **Morphology:** They are pleomorphic, mostly appear as long **filamentous threads**, ranging from 80–1000 nm, the average size being 665 nm (Marburg) to 805 nm (Ebola).
- **Highly fatal:** A great matter of concern is, of all the viral hemorrhagic fevers, Marburg and Ebola viruses have the highest mortality rates (25–90%).

Ebola Virus

Ebola virus has become a global threat, because of its recent explosive outbreak in 2014; which was declared by WHO, as a public health emergency of international concern.

History

Ebola virus disease in humans appeared first in 1976 in two simultaneous African outbreaks occurring in Sudan, and Democratic Republic of Congo. The latter outbreak occurred in a village near the **Ebola River**, from which the virus takes its name.

Species

Ebola virus has four stable subtypes or species (*Zaire, Sudan, Reston, Ivory Coast*); all differ from each other by up to 40% of their nucleotide sequences.

- Species are of epidemiological importance.
- The virus that has caused the 2014 West African outbreak belongs to the *Zaire* species.

Geographical Distribution

Since its discovery, Ebola virus has caused several outbreaks in various African countries affecting more than 27,479 documented cases with nearly 11,222 deaths.

The largest outbreak occurred in 2014; mainly affecting three West African countries-Guinea, Liberia and Sierra Leone. As of June 2015, about 27,040 suspected cases and 11,140 deaths were reported. Maximum cases were reported from Sierra Leone, but Liberia accouted for maximum deaths.

Reservoir

The reservoir hosts for Ebola viruses are unknown, but are suspected to be infected animals, such as a **fruit bat** or **primates** (apes and monkeys).

Transmission

In every outbreak, Ebola virus is introduced to human population through **close contact** with the blood, secretions, organs or other body fluids of infected animals such as chimpanzees, gorillas, fruit bats or monkeys.

- **Human-to-human transmission:** Once introduced to humans, Ebola virus spreads among people via **direct contact** (through broken skin or mucous membranes of eyes, nose, or mouth) with
  - Blood, secretions, organs or other bodily fluids of infected people
  - Infected surfaces and materials (e.g. bedding, clothing, syringes, etc.)
- Health-care workers and close contacts/family members of infected individuals are at greater risk of contracting the infection.
- Ebola virus can stay in semen for up to 3 months, although sexual transmission has not been reported yet.

Clinical Manifestations

- Incubation period is about 2–12 days (average being 8–10 days).
- Common symptoms include fever, headache, muscle pain and sore throat, followed by:
  - Abdominal pain, vomiting and diarrhea
  - Rash with hemorrhages (bleeding or bruise), often leading to shock and death.

Laboratory Diagnosis

- **Serum antibody** detection:
  - ELISA detects both IgM and IgG separately by using recombinant nucleoprotein (NP) and glycoprotein (GP) antigens.
  - Other antibody detection assays include immunofluorescence test and antibody-phage indicator assay.
- **Serum antigen** detection by capture ELISA. The target proteins are NP, VP40, and GP.
- **Molecular methods** such as RT-PCR and real time RT-PCR assays are useful to detect the viral RNA
- **Electron microscopy** of the specimen shows typical filamentous viruses (Fig. 49.1).
- **Virus isolation in Vero cell line:** Processing the specimen should be carried out in biosafety level-4 cabinets as there is a great risk of laboratory spread of the virus.

TREATMENT — Ebola virus

Supportive care such as rehydration and symptomatic treatment improves survival. No proven treatment or vaccine is available yet.

Measures Taken in India

There is no confirmed case documented yet in India.

- However, because of risk of contracting infection from travellers, strict vigilance is going on in the airports of India.

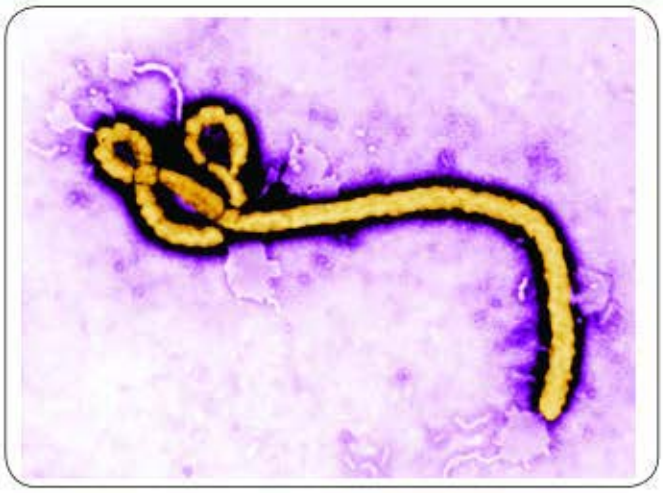

Fig. 49.1: Ebola virus, filamentous shaped (Electron micrograph)

Source: ID# 10815, Public Health Image Library, /Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- Any person presenting with an acute onset of fever who has been in Guinea, Liberia, Sierra Leone or Mali in past 21 days are kept in quarantine in the airports until tested negative for Ebola virus infection.

Marburg Virus

Marburg virus disease was first reported in Germany and Yugoslavia (1967) among laboratory workers exposed to tissues of African green monkeys imported from Africa.

- Since then, over 450 cases have been reported in various African countries such as Kenya, South Africa, Democratic Republic of Congo, Uganda and Angola.
- The most recent outbreak was in Angola(2005), affecting 252 people with 227 deaths (with mortality rate of 90%).

CORONAVIRUSES

Morphology

Coronaviruses are enveloped; carrying petal or club-shaped or crown-like peplomer spikes giving appearance of solar corona (Fig. 49.2).

- They are large (120–160 nm) spherical viruses having a helical symmetry.
- They possess linear, positive-sense ssRNA of 26 to 32 kbp size, largest among the non-segmented RNA viruses.

Classification

Coronaviridae family contains two sub families Coronavirinae and Torovirinae. The former has been grouped into four genera—*Alphacoronavirus, Betacoronavirus, Gammacoronavirus* and *Deltacoronavirus*. Most of them infect animals except *Gammacoronavirus* species, which are the pathogens of birds. Human infection is uncommon except few who have adapted to human conditions.

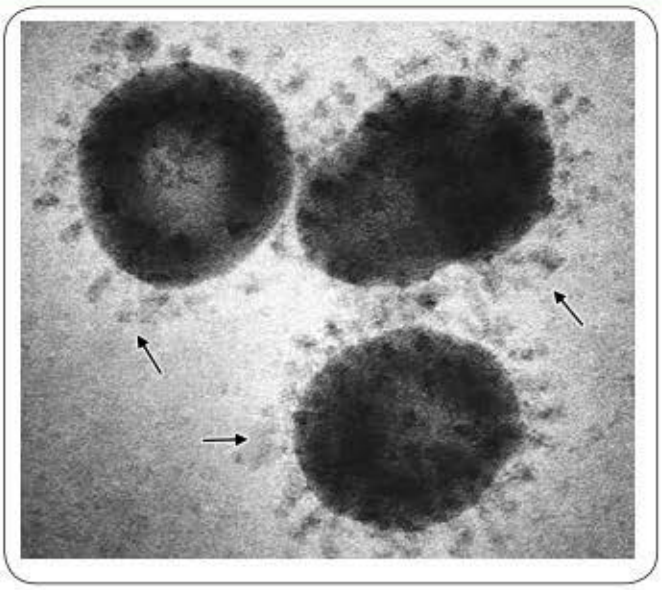

Fig. 49.2: Coronavirus (Petal or club shaped peplomers). Electron micrograph (arrows showing)

Source: ID# 10270, Public Health Image Library, /Centers for Disease Control and Prevention (CDC), Atlanta/Dr. Fred Murphy; Sylvia Whitfield (*with permission*)

Human Coronavirues

There are six recognized Coronaviruses that are known to cause human infections; most of them belong to *Betacoronavirus* except the first two which belong to *Alphacoronavirus*.

1. Human coronavirus 229E
2. Human coronavirus NL63 (New Haven Coronavirus)
3. Human coronavirus OC43
4. Human coronavirus HKU1
5. SARS-CoV (Severe Acute respiratory syndrome coronavirus)
6. MERS-CoV (Middle East respiratory syndrome coronavirus).

Most human coronaviruses are widespread affecting people of most part of the world and produce mild upper respiratory tract infection and occasional diarrhea.

Two exceptions are SARS-CoV and MERS-CoV which are geographically restricted, transmitted from man to man and have produced outbreaks of severe respiratory disease with higher mortality.

Transmission

Human coronaviruses spread by coughing, sneezing, and close personal contact, such as touching mouth, nose, or eyes or shaking hands. SARS-CoV can also spread via droplets and rarely spread through the air (airborne spread).

SARS-CoV (severe acute respiratory syndrome coronavirus)

- **History:** SARS was first recognized in China in 2003 by WHO physician Dr. Carlo Urbani. He diagnosed it in a businessman who had traveled from China, through Hong Kong, to Hanoi, Vietnam. The businessman and the doctor who first diagnosed SARS both died from the illness.
- **Epidemiology:** During 2003 outbreak, the SARS virus, spread from Asia to various regions of the world causing nearly 8098 cases in 29 countries, with over 774 deaths. However, India remained free from the infection. Since 2004, no case has been reported from anywhere in the world.
- **Source:** SARS-CoV infection in humans is believed to be contracted from animals, including monkeys, Himalayan palm civets, raccoon dogs, cats, dogs, and rodents.
- **Clinical manifestation** includes severe lower respiratory tract infection; characterized by muscle pain, headache, sore throat and fever, followed by the onset of respiratory symptoms mainly cough, dyspnoea and pneumonia.

MERS-CoV (middle east respiratory syndrome coronavirus)

MERS-CoV has recently caused a severe form of lower respiratory illness with a mortality of 30%.

Epidemiology: It was first reported in Saudi Arabia in 2012.

- Since then, several hundreds of cases have been reported from various countries located in and around the Arabian Peninsula such as Saudi Arabia, UAE, Qatar, Oman, Jordan, Kuwait, Yemen, Lebanon and Iran.
- It is not reported from India yet.

Source though unknown, it is believed to have been acquired from camels and bats.

People at increased risk for MERS-CoV infection include:

- Recent history of travel from the Arabian Peninsula within 14 days
- Close contacts of a confirmed case of MERS
- Healthcare personnel not using recommended infection control precautions
- People with exposure to infected camels

Clinical manifestation

- Incubation period is about 2–14 days.
- Severe acute respiratory symptoms appear such as fever, cough and shortness of breath may appear.
- Some people may develop gastrointestinal symptoms including diarrhea and nausea/vomiting.
- Complications such as pneumonia and kidney failure occur, especially in people with underlying comorbid conditions.

Laboratory Diagnosis

- **Antigen detection:** Coronavirus antigens in the respiratory epithelial cells may be detected by ELISA using specific monoclonal antibody.
- **Electron microscopy** can be used to detect enteric coronaviruses from stool.
- **RNA detection:** RT-PCR assays are useful to detect coronavirus RNA in respiratory secretions and in stool samples and SARS-CoV RNA from blood.
- **Isolation** of human coronaviruses in cell culture has been extremely difficult. Traditional **tracheal ring culture** is no longer in use. SARS-CoV was isolated from respiratory specimens using Vero cell line.
- **Serum antibody detection:** ELISA and hemagglutination inhibition test are available. Rising titer of antibody between acute and convalescent sera can be used to establish the diagnosis.

Treatment and Prevention

There are no specific drugs or vaccine available for coronavirus infections.

- **Control measures** include:
  - Isolation of patients
  - Quarantine of exposed people
  - Travel restrictions if needed
  - Use of gloves, gowns, goggles and respirators by healthcare workers
  - Thorough and frequent hand washing
  - Avoiding personal contact, such as kissing, or sharing cups or eating utensils, with sick people
  - Avoiding contact with camels, uncooked camel milk or meat.
- **Taking effective control measures** was the main reason behind preventing SARS transmission in 2003.

SLOW VIRUSES AND PRIONS

Slow virus diseases including prion diseases are a group of neurodegenerative conditions affecting both humans and animals, characterized by:

- **Long incubation period**, ranging from months to years because of the long doubling time of slow viruses of 5.2 days or more.
- **Predilection for CNS:** Slow viruses usually affect the central nervous system (CNS):
  - This cause vacuolation of neurons (spongiform changes), with deposition of amyloid like plaques and gliosis
  - Common symptoms include loss of muscle control shivering, tremors and dementia
  - Invariably fatal
- Strong **genetic** predisposition
- Slow viruses and prions **lack in antigenicity**; hence there is:
  - Lack of immune response and interferon production against the viral proteins
  - Lack of associated inflammation
- Does not produce cytopathologic effect *in vitro*

Slow virus diseases are either caused by (Table 49.2):

TABLE 49.2: Slow viral diseases

Disease	Agent	Hosts	Nature of Disease
Due to Conventional viruses			
Subacute sclerosing panencephalitis	Measles virus variant	Humans	Chronic sclerosing panencephalitis
Progressive multifocal leukoencephalopathy	• Polyomavirus • JC virus	Humans	CNS demyelination
Visna virus	Retrovirus	Sheep	CNS demyelination
Maedi virus	Retrovirus	Sheep	Progressive pneumonia
Due to Unconventional viruses: Prions			
Kuru	Prion	Humans, monkeys chimpanzees	Spongiform encephalopathy
Creutzfeldt-Jakob disease	Prion	Humans, monkeys chimpanzees	
Gerstmann-Sträussler-Scheinker disease	Prion	Humans	
Fatal familial insomnia	Prion	Humans	
Scrapie	Prion	Sheep, goats, mice	
Bovine spongiform encephalopathy	Prion	Cattle	
Transmissible mink encephalopathy	Prion	Mink	
Chronic wasting disease	Prion	Mule deer, elk	

Abbreviations: JC, John Cunningham; CNS, central nervous system

- **Conventional viruses:** Examples include:
  - Subacute sclerosing panencephalitis
  - Progressive multifocal leukoencephalopathy
  - Visna and Maedi
- **Unconventional** transmissible slow viruses-termed as "prions".

Slow Virus Diseases Due to Conventional Viruses

Subacute Sclerosing Panencephalitis (SSPE)

SSPE is a rare disease of young adults caused by a defective measles virus, characterized by slow progressive demyelination of the CNS ending in death.

- Such measles viruses have a defective transcription and are unable to synthesize envelope proteins; hence, for survival, they establish a chronic persistent infection in the neural cells. Large numbers of viral nucleocapsid structures are produced in the neurons and glial cells.
- **Diagnosis:** Patients with SSPE have high titers of anti-measles antibody in cerebrospinal fluid (CSF) except that antibody to the M protein is frequently lacking. However, virus isolation is very difficult.

Progressive Multifocal Leukoencephalopathy (PML)

PML is caused by JC virus a member of the family Polyomaviridae.

- It infects the oligodendrocytes of brain and causes demyelination of CNS.
- PML occurs in about 5% of patients with AIDS or other immunosuppressed conditions.

Visna and Maedi

Visna and Maedi viruses are closely related retroviruses that cause slowly developing infections in sheep.

- Visna virus causes demyelination of CNS
- Maedi virus causes a slow progressive fatal hemorrhagic pneumonia of sheep.
- Symptoms appear after a long incubation period of months to years.
- Disease progresses either rapidly (weeks) or slowly (years).

Slow Virus Diseases due to Unconventional Viruses/ Prion Diseases

Prions are infectious protein particles that lack any nucleic acid. They are filterable like viruses; but are resistant to wide range of chemical and physical agents of sterilization. There are several prion diseases of humans and animals; *Scrapie* being the prototype.

Prion proteins have two isoforms

- PrP^{Sc} is the prion protein that causes disease. It is so named because, it is identified in the purified preparations of scrapie prions.
- PrP^{C} is the normal cellular isoform of the prion protein present on the cell membrane of mammals. It is encoded in chromosome 20. It is the precursor of PrP^{Sc}, they differ from each other in many respects (Table 49.3).

TABLE 49.3: Differences between PrP^{C} and PrP^{Sc}

Features	PrP^{C}	PrP^{Sc}
Full form	Prion protein cellular	Prion protein scrapie
	Normal isoform of prion protein present in man/animals	Prion protein that causes prion disease in man/animals
Structure	Elongated polypeptide, rich in α-helix and has little β-structure	▪ Globular polypeptide ▪ Contains less α-helix but more β-structure
Location	Anchored to the cell membrane	Cytoplasmic vesicles
Protease	Sensitive	Resistant
Turnover	Hours	Days

Mechanism of Prion Diseases

Though many theories have been proposed but that of **Stanley B. Prusiner** (Nobel prize winner, 1997) had clearly explained the detailed mechanism how an aberrant protein could cause disease.

- Once infected, the prion proteins (PrP^{Sc}) are carried to the neurons. They bind to the normal PrP^{C} on the cell surface.
- This causes the release of PrP^{C} from cell surface followed by their conversion into the disease-causing isoform (PrP^{Sc}). This is a **post translational modification** by which the elongated polypeptide PrP^{C} become globular polypeptide PrP^{Sc}.
- The cell synthesizes new PrP^{C} and the cycle is repeated; as a result, large amount of PrP^{Sc} is formed,.
- PrP^{Sc} are aggregated as **amyloid-like plaques** in the brain. As these plaques consist of host proteins, there is lack of an immune response or inflammation.
- PrP^{Sc} are internalized by neurons and get accumulated inside the **cytoplasmic vacuoles** giving the cell a spongiform appearance.
- **Spongiform encephalopathy** is the main pathology seen in CNS, characterized by:
  - Vacuolation of the neurons
  - Formation of amyloid-containing plaques and fibrils
  - Proliferation and hypertrophy of astrocytes
  - Fusion of neurons and adjacent glial cells

Clinical Manifestations of Prion Diseases

Incubation period of prion diseases varies from months to years (longest being 30 years). But once the disease sets in, progression is fast.

- Prodromal phase lasts for 3–5 months, followed by appearance of manifestations such as loss of muscle control, shivering, myoclonic jerks, tremors, loss of coordination and rapidly progressive dementia.
- Death occurs within 1 year of onset of disease.

Prion Diseases of Animals

- **Scrapie:** It is the prototype of prion diseases that has been extensively studied.

  Natural scrapie is a prion disease of sheep.
  - Transmission occurs vertically in sheep from parent to offspring and less often by direct contact.
  - After an incubation period of 2 years, the affected sheep become irritable and develop intense pruritus, scraping themselves against trees and rocks; hence, the name scrapie is given.
  - Gradually, emaciation and paralysis occurs leading to death.

  Experimental scrapie: The disease can be experimentally transmitted to various animals (several breeds of sheep and as well as other animals) by injection of neural tissues of infected sheep.
  - In hamsters and mice, the incubation period is less, which has facilitated the study of the disease.
  - Susceptibility: Different breeds of sheep exhibit marked genetic differences in susceptibility to infection (ranging 0–80%); whereas goats are almost 100% susceptible.
- **Mink encephalopathy:** It is a scrapie-like disease of mink transmitted by feeding the minks on scrapie infected sheep meat.
- **Bovine spongiform encephalopathy (BSE, "mad cow disease"):** It has been enzootic in cattle in Great Britain since 1986.
  - The epidemic peaked in 1993 infecting over 1 million of cattle with infection spreading to European countries.
  - BSE is transmitted due to the practice of feeding the cattle with meat and bone meal contaminated with scrapie or BSE prions.

Human Prion Diseases

- **Kuru:** It was seen only in the Eastern Highlands of New Guinea and was spread by customs surrounding ritual cannibalism of dead relatives infected with the disease. Since this practice has ceased, the disease has disappeared now.
- **Classical Creutzfeldt-Jakob disease (CJD):** It is the most common form of prion disease in humans. It typically presents with dementia and myoclonus, is relentlessly progressive, and generally causes death within a year of onset.
- **Iatrogenic CJD:** Most CJD occur in patients between 50 years and 75 years of age and are transmitted by direct contact during some medical or surgical procedures contaminated with prion tissues such as:
  - Corneal transplantation
  - Electroencephalogram (EEG) electrode implantation
  - Dura mater graft implantation (>160 cases have been recorded)

- Human growth hormone and pituitary gonadotropin therapy (>180 cases have been recorded).

- **Sporadic CJD:** It occurs due to somatic mutation or spontaneous conversion of PrP^{C} into PrP^{Sc}. The incidence of sCJD is about one case per million populations.
- **Familial CJD** and its variants such as Gerstmann-Sträussler-Scheinker syndrome and fatal familial insomnia are rare forms that run in families and are due to germ line mutations in the PrP gene.
- **Variant CJD:** In contrast to the classical CJD, vCJD occurs below 30 years and is believed to be transmitted through the consumption of contaminated beef with BSE prions. More than 190 cases of vCJD have occurred, mainly from Britain (where BSE is prevalent).

Laboratory Diagnosis

- **Measurement of PrP^{Sc}** by conformation dependent immunoassay is the most definitive diagnostic tool for prion diseases.
- **Brain MRI:** More than 90% of patients show increased intensity in the basal ganglia and cortical ribboning.
- **Neuropathological diagnosis** in brain biopsies: The pathologic hallmarks of prion diseases seen under light microscopy, are spongiform degeneration and astrocytic gliosis with lack of inflammatory response.
- **Sequencing the PRNP gene** to identify the mutation-this is important in familial forms of prion diseases.
- **Stress protein 14-3-3** is elevated in the CSF.
- **Abnormal EEG** (electroencephalogram): In late stage of the disease, high-voltage, triphasic sharp discharges are observed.

TREATMENT **Prion diseases**

There is no known effective therapy for preventing or treating prion diseases. Several trials using drugs such as quinacrine and anti-PrP antibodies have shown to eliminate PrP^{Sc} from the cultured cells, but they failed to do so *in vivo*.

Decontamination

Prions are extremely resistant to most of the common sterilization procedures. Recommended methods for sterilization of material contaminated with prion proteins are:

- Autoclaving at 134°C for 1–1.5 hour
- Treatment with 1 N NaOH for 1 hour and
- Treatment with 0.5% sodium hypochlorite for 2 hours

Prions if bound to the stainless steel should be treated with an acidic detergent solution prior to autoclaving; rendering them susceptible to inactivation.

VIRAL GASTROENTERITIS

Viral etiology accounts for the most of the acute infectious gastroenteritis worldwide (Table 49.4). Viral gastroenteritis most commonly occurs among children. However persons of all ages can be affected. Several enteric viruses can cause acute gastroenteritis in humans, most common being rotavirus.

TABLE 49.4: Viruses causing gastroenteritis

Virus	Genome	Gastroenteritis features
Rotavirus*	Segmented dsRNA	**Group A:** Most common cause of severe endemic diarrheal illness in children worldwide **Group B:** Causes outbreaks of diarrhea in adults in China.
Caliciviruses		
Norovirus	ssRNA	Causes outbreaks of vomiting and diarrheal illness in all ages (especially in older children and adults)
Sapovirus	ssRNA	Causes sporadic cases and occasional outbreaks of diarrheal illness in infants, young children, and in elderly
Astrovirus	ssRNA	
Adenovirus* (type 40 and 41)	dsDNA	Second most common viral agent of endemic diarrheal illness of infants and young children worldwide

*Clinical severity is maximum

Rotavirus

Rotaviruses are the most common cause of diarrheal illness in children.

Morphology

Rotaviruses are about 60–80 nm in size and possess icosahedral symmetry.

- Surrounded by a triple layered capsid.
- Possess segmented dsRNA (11 segments)
- **Proteins:** There are six structural viral proteins (VP1 to VP7 except VP5) and six non-structural proteins (NSP1-6)
- Viral protein (VP6) is group-specific.
- **VP7** (forms the outer capsid layer) and **VP4** (forms spikes that emanate through the outer capsid layer) are strong inducers of neutralizing antibodies and are type specific.

Classification of Rotaviruses

Rotaviruses belong to the family Reoviridae; the only virus family to have dsRNA.

- **Traditional groups:** Rotaviruses are further classified into seven major groups (A–G) based on the antigenic composition of the group specific VP6. Most human diarrhea is caused by group A and, to a much lesser extent, by groups B and C.

Contd...

Contd...

- **Binary system of typing-VP7** (a glycoprotein or G-type antigen) and **VP4** (a protease sensitive protein or P-type antigen) are used for the typing of rotaviruses.
  - Both serotyping and genotyping methods are available.
    - VP7 shows concordant results between serotypes and genotypes; hence,the serotype format is routinely used for typing of VP7 and the serotypes are expressed by their serotype numbers, e.g. G1, G2, etc.
    - However, for VP4, the serotypes and genotypes do not match. More so, standardizing the VP4 serotyping assays is challenging. Hence, the genotype format is routinely used for typing of VP4 and the genotypes are denoted in brackets, e.g. P[1], P[2] etc.
  - The most widely used format for expressing rotavirus types is combination of *G serotypes* and *P genotypes, e.g.* G1P[8].
  - Currently, 19G and 28[P] types are known. The most common type seen in the world as well as in India is **G1P[8]** type, which accounts for nearly 70% of total isolates.
  - The diversity among the rotavirus types is more commonly encountered in areas with poor hygiene.

Pathogenesis

Rotaviruses infect and ultimately destroy the mature enterocytes in the villi of the proximal small intestine; however, the gastric and colonic mucosa are spared.

- They multiply in the cytoplasm of enterocytes and damage their transport mechanisms resulting in secretory diarrhea.
- The non-structural protein-NSP4, acts as enterotoxin and induces secretion by altering epithelial cell function and permeability.
- Damaged cells may slough into the intestinal lumen and release viruses in the feces; the count may exceed up to 10^{10} viral particles per gram of feces.
- Viral excretion usually lasts 2–12 days, but may be prolonged in patients with poor nutrition or HIV infection.

Clinical Manifestation

The incubation period is about 1–3 days. It has an abrupt onset, characterized by vomiting followed by watery diarrhea, fever and abdominal pain.

- Recovery usually occurs in majority, but a few children may suffer from severe loss of electrolytes and fluids leading to dehydration.
- Infected adults are usually asymptomatic but show seroconversion. However, epidemics or large outbreaks have occurred in adults, especially in closed populations (e.g. geriatric ward).
- Group B rotaviruses have been implicated in large outbreaks of severe gastroenteritis in adults in China.

Epidemiology

Rotaviruses are the single most important cause of gastroenteritis in young children.

- Worldwide, about 3–5 billion diarrheal episodes in children occur annually resulting in nearly 1 million deaths especially from sub-Saharan Africa and Southern Asia.
- **In developing countries like India:** Rotavirus illness occurs at a younger age, is less seasonal and more frequently caused by diverse and uncommon serotypes.
- Whereas in temperate climate, Group A rotavirus causes outbreaks in cooler months.

Laboratory Diagnosis

- **Direct detection of virus:** Feces collected early in the illness is the most ideal specimen. Rotaviruses can be demonstrated in stool by:
  - **Immunoelectron microscopy (IEM):** Rotaviruses have a sharp edged triple shelled capsid; look like the spokes grouped around the hub of a wheel (Fig. 49.3)
  - **Isolation** of rotavirus is difficult. Rolling of tissue cultures may be attempted to enhance replication.
- **Detection of viral antigen** in stool by ELISA and latex agglutination based methods.
- **RT-PCR** is the most sensitive detection method for detection of rotavirus from stool.
- **Typing methods:** G serotypes and P genotypes of rotaviruses can be detected by RNA sequence typing and neutralization test respectively.
- **Serologic tests** (ELISA) can be used to detect the rise of antibody titer. This may be useful for seroprevalence purpose.

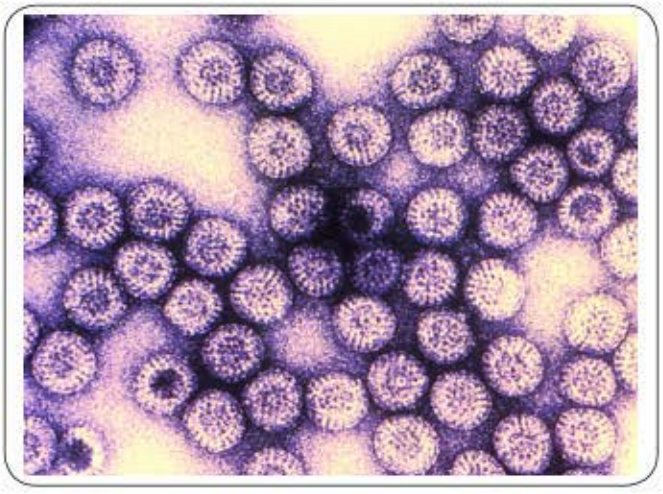

Fig. 49.3: Rotavirus (electron micrograph)

Source: Public Health Image Library, /ID# 15194/Dr Erskine L. Palmer/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Viral gastroenteritis**

- **Treatment** is mainly supportive, to correct the loss of water and electrolytes such as oral or parenteral fluid replacement.

Prevention

- **Vaccine:** Human live attenuated rotavirus vaccine (**Rotarix**) is available.
  - It consists of live attenuated human strains of rotavirus serotypes G1, G2, G3, G4 and G9.
  - Schedule: It is administered by oral route, two doses at 2 and 4 months after birth.
  - Most serious complication following rotavirus vaccine is intussusception.
- **General preventive** measures to improve hygiene and sanitation are necessary for prevention of infection.

Other Agents of Gastroenteritis

- **Family Caliciviridae** comprises of four genera; out of which two consists of important agents of human diarrhea—(1) genus *Norovirus*, which includes the Norwalk viruses and (2) genus *Sapovirus*, which includes the Sapporo-like viruses
  - They are icosahedral, 27–40 nm in size; possess **cup-like depressions** on the capsid surface typically observed under electron microscope. They are single stranded (+) sense RNA and a single major structural protein.
  - Norwalk virus is the most important cause of epidemic viral gastroenteritis in adults.
  - Sapoviruses cause sporadic cases and occasional outbreaks of diarrheal illness in infants, young children, and the elderly
  - Laboratory diagnosis and treatment are similar to that of rotavirus. They are not cultivable.
- **Adenoviruses (types 40 and 41)** are the second most common viral agents of endemic diarrheal illness of infants and young children worldwide, responsible for 2–12% of all diarrhea episodes in young children.
- **Astroviruses** exhibit a distinctive **star-like** morphology under the electron microscope
  - They are of 28–30 nm size with an icosahedral symmetry and contain a positive sense, ssRNA.
  - At least seven serotypes have been identified, of which serotype-1 is the most common.
  - Astroviruses cause sporadic cases and occasional outbreaks of diarrhea in infants, young children and in elderly.
- **Respiratory viruses:** Diarrhea has also been reported as a part of manifestations of certain respiratory viruses such as:
  - SARS coronavirus
  - Influenza A/H5N1 virus
  - Influenza A/H1N1 virus (the 2009 pandemic strain)
- **Toroviruses** and **Picobirnaviruses** cause gastroenteritis in a variety of animals, but their role as primary cause of gastroenteritis in humans remains unclear.

BORNA DISEASE VIRUS

Borna disease virus (BDV) is a highly neurotropic virus which causes neuropsychiatric disorders in horses and sheep, manifested by behavioral abnormalities usually ending in death.

- It is seen in certain areas of Germany.
- The disorder is immune-mediated; characterized by depostion of inflammatory cells in the brain.
- It belongs to the family Bornaviridae. It is enveloped, contains negative sense ssRNA, which replicates in the nucleus.
- Human infection has not been established yet, though serologic data suggest that BDV may be associated with neuropsychiatric disorders in humans.

EXPECTED QUESTIONS

I. Write short notes on:

1. Ebola virus
2. SARS CoV
3. Prion diseases
4. Viral gastroenteritis

II. Multiple Choice Questions (MCQs):

1. About Ebola virus true statement is:
   a. Incubation period is less than 48 hours
   b. Transmission is by oral route
   c. Specific treatment is available
   d. Cases are restricted to Guinea, Liberia and Sierra Leone

2. The most common viral cause of gastroenteritis:
   a. Rotavirus
   b. Norwalk virus
   c. Adenovirus
   d. Hepadnavirus

3. All are true about SARS EXCEPT:
   a. Epidemic is seen in India
   b. Spreads by droplet
   c. Diagnosed by PCR
   d. Caused by a type of coronavirus

4. Which of following is correct about prions?
   a. Destroyed by autoclaving at 121°C
   b. Long incubation period
   c. Nucleic acid present
   d. Immunogenic

5. Which of the following virus has club shaped peplomers and is a respiratory pathogen?
   a. Norwalk virus
   b. Hepadnavirus
   c. Rotavirus
   d. Coronavirus

Answers

1. d **2.** a **3.** a **4.** b **5.** d

CHAPTER 50

Hepatitis Viruses

Chapter Preview

- **Introduction**
- **Hepatitis A virus (HAV)**
- **Hepatitis B virus (HBV)**
- **Hepatitis C virus (HCV)**
- **Hepatitis D virus (HDV)**
- **Hepatitis E virus (HEV)**
- **Hepatitis G virus (HGV)**

INTRODUCTION

Hepatitis viruses are heterogeneous group of viruses that are taxonomically diverse (belong to different families) but all are hepatotropic; cause acute inflammation of the liver producing identical histopathologic lesions and similar clinical illness such as fever, nausea, vomiting, and jaundice.

Hepatitis viruses are classified into six types (Table 50.1):

1. Hepatitis A virus (HAV): It causes infectious hepatitis.
2. Hepatitis B virus (HBV): It causes serum hepatitis.
3. Hepatitis C virus (HCV): It is common cause of post-transfusion hepatitis.
4. Hepatitis D virus (HDV): It is a defective virus, needs HBV for its replication.
5. Hepatitis E virus (HEV): It is the agent of enterically transmitted non-A, non-B hepatitis.
6. Hepatitis G virus (HGV)

TABLE 50.1: Features of hepatitis viruses

Properties	HAV	HBV	HCV	HDV	HEV
Common name	Infectious hepatitis	Serum hepatitis	Non A non B or post-transfusion hepatitis	Delta agent	Non A non B enteric transmitted hepatitis
Family	Enterovirus-72 (Picornaviridae)	Hepadnaviridae	Flaviviridae	Unclassified viroid-like	Unclassified Caliciviridae-like
Genus	*Hepatovirus*	*Orthohepadnavirus*	*Hepacivirus*	*Deltavirus*	*Hepevirus*
Virion	27 nm, icosahedral	42 nm, spherical	60 nm, spherical	35 nm, spherical	30–32 nm, icosahedral
Envelope	No	Yes (HBsAg)	Yes	Yes (HBsAg)	No
Genome	ssRNA	dsDNA	ssRNA	ssRNA	ssRNA
Stability	Heat and acid-stable	Acid-sensitive	Ether-sensitive, acid-sensitive	Acid-sensitive	Heat-stable
Onset	Abrupt	Insidious	Insidious	Insidious	Abrupt
Age	▪ Children ▪ Young adults	▪ Young adults ▪ Toddlers and babies	Any age, but more common in adults	Any age (similar to HBV)	Young adults (20–40 years)
Route	Fecal-oral	▪ Blood (MC) ▪ Sexual ▪ Vertical	▪ Blood (MC) ▪ Sexual (+/–) ▪ Vertical (+/–)	▪ Blood (MC) ▪ Sexual (++) ▪ Vertical (+)	Fecal-oral
I.P (days)	15–45 (Average 30)	30–180 (Average 60–90)	15–160 (Average 50)	30–180 (Average 60–90)	14–60 (Average 40)
Fulminant disease	Rare (0.1%)	Rare (0.1–1%)	Rare (0.1%)	Frequent (5–20%)	▪ Usually rare (1–2%) ▪ Pregnancy: 20–40%

Properties	HAV	HBV	HCV	HDV	HEV
Carrier	None	Yes (0.1–30%)	Yes (1.5–3.2%)	Variable	None
Chronicity	None	Occasional (1–10%)	Common (85%)	Common	None
Oncogenic	No	Yes (neonate)	Yes	+/-	No
Prevalence	High	High	Moderate	Low, regional	Regional
Associated other feature	Secondary attack rate 10–20%	HCC, cirrhosis, Autoimmune disorder like AGN, arthritis, PAN	HCC, cirrhosis, Autoimmune disorders like AGN, arthritis, cryoglobulinemia	HCC, cirrhosis, fulminant hepatitis	▪ Secondary attack rate (1–2%) ▪ Rarely seen in western countries
Prognosis	Excellent	Worse with age	Moderate	▪ Acute-good ▪ Chronic- poor	Good
Prophylaxis	▪ Immunoglobulin ▪ Inactivated vaccine	▪ HBIG ▪ Recombinant vaccine	None	HBV vaccine (no vaccine for HBV carriers)	Vaccine (HEV239) (only in China)
Therapy	None	▪ Pegylated interferon ▪ Lamivudine	Pegylated interferon plus ribavirin	Interferon ±	None

Abbreviations: MC, most common; HCC, hepatocellular carcinoma; HBsAg, hepatitis B surface antigen; AGN, acute glomerulonephritis; HBIG, hepatitis B immunoglobulin; IP, incubation period; PAN, polyarteritis nodosa.

"Hepatitis F" (1994) was proposed for its association with transfusion-associated hepatitis, but further investigations failed to confirm the existence of the virus, therefore it was delisted as a cause for infectious hepatitis.

However, there are many viruses other than hepatitis viruses that can cause sporadic hepatitis, such as yellow fever virus, cytomegalovirus, Epstein-Barr virus, herpes simplex virus, rubella virus, and enteroviruses.

HEPATITIS A VIRUS

Hepatitis A virus belongs to the family Picornaviridae. It was originally designated as "enterovirus 72", but based on the nucleotide and amino acid sequences, it was later assigned to a new genus, *Hepatovirus* under Picornaviridae family.

Morphology

- HAV is 27–32 nm in size, spherical particle with icosahedral symmetry, containing a linear ssRNA.
- It has only one serotype, doesnot cross-react with other hepatitis viruses; however it can be typed into seven genotypes based on gene sequences.

Resistance

HAV is relatively resistant to disinfectants.

- It is stable to acid, heat (60°C for 1 hour), and ether (20%) and can be preserved in dried state for 1 month and stored for years at –20°C.
- HAV is destroyed by autoclaving, by boiling in water for 5 minutes, by hot air oven, by ultraviolet (UV) rays and by treatment with formalin or chlorine (10–15 ppm for 30 minutes).

Mode of Transmission

- HAV is transmitted principally by fecal-oral route.
- Rarely, HAV can also be transmitted by sexual (homosexuals through oro-genital contact) and parenteral routes (infected blood products or needle pricks).

Epidemiology

- **Hosts:** Humans are the only host for HAV. However, experimental infection may be induced in chimpanzees.
- **Age:** Children and adolescents (5–14 years of age) are most commonly affected, majority remain **subclinical** (80–95%), but excrete virus in feces for longer time. Adults are more icteric (75–90%) than children with higher mortality rate. Anicteric to icteric cases ratio is about:
  - In children: 12:1
  - In adults: 1:3
- **Risk factors:** Poor personal hygiene and overcrowding are the most important risk factors.
  - In **developing countries** including India with poor personal hygiene and overcrowding, most of the children (90%) are infected with HAV by the age of 10 years. Adults have protective antibodies and are mostly immune to HAV.
  - However, in **developed countries** with improved hygiene, the incidence is decreasing and there is trend of shift of infection towards the older age.
- **Outbreaks** are common in summer camps, day care centers, families and institutions, neonatal ICUs, and among military troops.

- **Recurrent epidemics** and sudden, explosive epidemics are common and usually result from fecal contamination of a single source (e.g, drinking water, milk or food such as raw vegetables, salad, frozen strawberries, green onions and shell fish). The largest epidemic was reported from Shanghai (1988, > 3 lakh cases).
- **Seasonal incidence:** Though HAV infection is widespread throughout the year, it tends to peak in late rainfall and in early winter.
- **Virus excretion:** Viral excretion in feces may be 2 weeks before to 2 weeks after the appearance of jaundice (however, viremia occurs from -2 weeks to +1 week of jaundice).

Clinical Manifestation

- Incubation period is about 15–45 days (mean 30 days).
- Onset is relatively abrupt (sub-acute).
- **Clinically,** HAV infection is indistinguishable from other hepatitis viruses; characterized by:
  - Pre-icteric phase (mainly gastrointestinal symptoms such as nausea and vomiting) followed by;
  - Icteric phase or jaundice (dark urine, yellowish sclera and mucus membrane)
- Complete recovery occurs in most (98%) cases.
- There is no chronic or carriers state.
- **Complications may occur rarey such as:**
  - Fulminant hepatitis; characterized by severe necrosis of hepatocytes, may occur rarely.
  - Relapsing hepatitis; may develop weeks to months after apparent recovery from acute hepatitis.
  - Cholestatic hepatitis; characterized by protracted cholestatic jaundice and pruritus.

Laboratory Diagnosis

- **Anti HAV antibody detection:**
  - IgM antibodies appear during the acute phase, peak about 2 weeks after the elevation of liver enzymes and disappear within 3–6 months (Fig. 50.1).
  - IgG antibodies appear a week after the appearance of IgM and persist for decades.
  - **Interpretation:**
    - Anti-HAV IgM positive–indicates acute infection with HAV.
    - Anti-HAV IgG antibody detection in the absence of IgM indicates past infection or recovery.
    - ELISA is the method of choice; however many rapid test formats are also available.
- **Detection of HAV particles:** HAV appears in stool from -2 to +2 weeks of jaundice. It can also be detected from liver, bile, and blood by immunoelectron microscopy.
- **HAV antigen detection:** ELISA format is available to detect HAV antigen from stool sample from –2 to +2 weeks of jaundice.

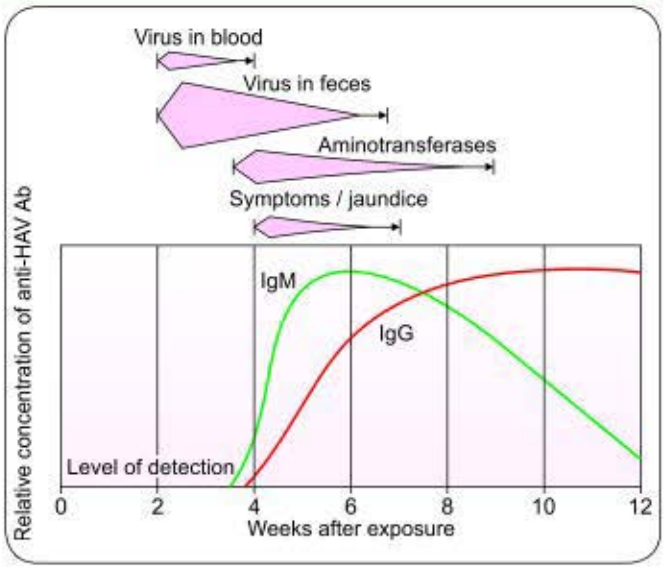

Fig. 50.1: Course of HAV markers with symptoms

- **Isolation:** HAV is very difficult to grow in cell line; though various primate cell lines are susceptible. HAV is the only hepatitis virus where isolation has been attempted.
- **Non-specific findings:** Such as elevated liver enzymes and serum bilirubin level.

TREATMENT — Hepatitis A virus

There is no specific antiviral drug available against HAV.

Prevention and Containment of Infection

General preventive measures should be attempted to improve hygiene such as:

- Hand washing before and after use of toilet.
- Sanitary disposal of infected fecal material by disinfection with 0.5% hypochlorite.
- Purification of drinking water by effective filtration and adequate chlorination (with at least 1 mg/L of residual chlorine).
- Use of boiled water (boiling for at least 5 minute) during outbreaks.

Vaccines

- **Formaldehyde inactivated vaccine:** It is prepared from human fetal lung fibroblast cell lines such as MRC-5 and WI 38. It is given to children after 12 months of age. Single dose is administered by intramuscular route (deltoid) followed by booster at 6–12 months gap. Its protective efficacy is about 94%.
- **Live attenuated vaccine:** It is given as single dose, subcutaneously. It uses H2 and L-A-1 strains of HAV, prepared in human diploid cell line (China).

- Both vaccines are highly immunogenic, produce long lasting immunity, possibly life-long.

Human Immunoglobulin (HAV-Ig)

It is extremely useful for post-exposure prophylaxis of **intimate contacts** (household, day care centers) of persons with hepatitis A or to the **travellers**.

- Dosage of 0.02 mL/kg is recommended which gives protection for about 1–2 months.
- It should be administered as early as possible after exposure; (within 2 weeks).
- However, HAV-Ig is not necessary for those who have already vaccinated, casual contacts (office, factory, school, or hospital), and elderly persons (likely to be immune).

HEPATITIS B VIRUS

Hepatitis B virus (HBV) is the most widespread and the most important type among hepatitis viruses. Though it commonly produces an acute self-limiting hepatitis which may be subclinical or symptomatic, it is also capable of causing a range of hepatic complications including chronic hepatitis, fulminant hepatitis, cirrhosis of liver and liver cancer.

- HBV is the only DNA virus among hepatitis viruses. It was discovered by Blumberg in 1963.
- It belongs to the family Hepadnaviridae, under the genus *Orthohepadnavirus*. This family also includes hepatitis viruses of lower animals (e.g, woodchucks, squirrels and ducks).

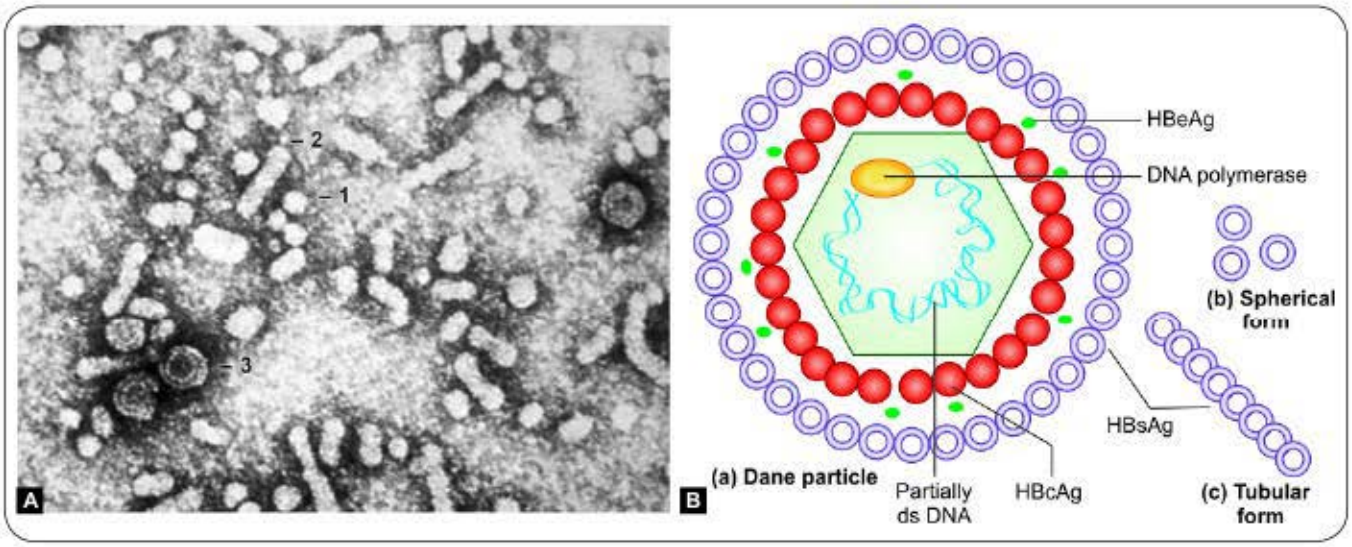
Morphology

Electron microscopy of serum of the patients infected with HBV reveals three morphologic forms (Figs 50.2A and B):

1. **Spherical forms:** Most numerous, small forms measuring 22 nm in diameter. These particles are exclusively made up of HBsAg.
2. **Tubular or filamentous forms:** It also have the same diameter but 200 nm long. They are also exclusively made up of HBsAg.
3. **Complete form or Dane particles:** They are less frequently observed. They are larger, 42 nm size spherical virions; made up of:
   - **Outer surface envelope:** HBsAg (Hepatitis B surface antigen).
   - **Inner 27 nm size nucleocapsid:** It consists of core antigen (HBcAg) and pre-core antigen (HBeAg) and partially double stranded DNA.

Viral Antigens

- **Hepatitis B surface antigen (HBsAg):** HBsAg was previously called **Australia antigen** as it was first observed in the serum of an Australian Aboriginal person (1965).
- HBsAg is antigenically complex and contains two components—(1) common group reactive antigen 'a' epitope and (2) two pairs of type specific antigens d/y and w/r; only one member of each pair being present at a time.
- Thus, four subtypes of HBsAg have been observed: adw, ayw, adr, and ayr.



Figs 50.2A and B: A. Electron microscopic appearance of hepatitis B virus, showing 1-spherical form, 2-tubular form and 3-Dane particle; **B.** Schematic diagram

Source: A. Public Health Image Library, /Centers for Disease Control and Prevention (CDC), B. Atlanta/ ID# 5631 (*with permission*)

- **Hepatitis B core antigen (HBcAg):** HBcAg forms the intracellular core protein. It is not secreted and does not circulate in blood, but can be demonstrated in hepatocytes by immunofluorescence.
- **Hepatitis B precore antigen (HBeAg):** HBeAg is a non-particulate soluble antigen possessing a signal protein which enables it to be secreted. It is therefore present in circulation.

Typing of HBV

Serotypes

HBV is divided into four major serotypes (adr, adw, ayr, ayw) based on antigenic epitopes present on its envelope protein HBsAg.

- The immunity is not serotype specific as the dominant 'a' antigen is shared by all. But they are useful for epidemiologic investigations, as all the cases during an epidemic would likely to have the same subtype.
- Serotypes exhibit distinct geographical distribution.
  - adw is the predominant subtype in Europe, Australia and America.
  - In India adr is the prevalent subtype in South and East India; whereas ayw is prevalent in Western and Northern India.

Genotypes

HBV can also be divided into eight genotypes (A–H) according to overall nucleotide sequence variation of the genome. Genotypes A and D are prevalent in India.

Viral Genome

The HBV genome (Fig. 50.3) consists of partially circular dsDNA of 3200 bp in length.

- The minus strand of DNA (L or long strand) is complete and full-length and is identical in all HBV isolates.
- The positive strand (S or short strand) is incomplete and of variable length (50–80%).

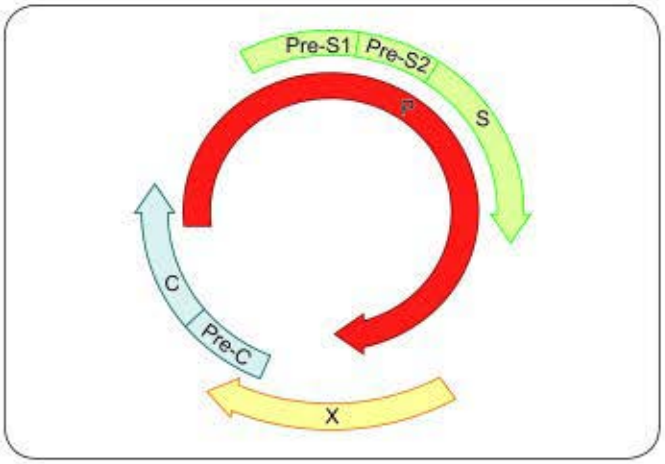


Fig. 50.3: HBV genome

Hepatitis B virus genome is compact and consists of four overlapping genes:

1. **S gene:** It has three regions—(1) S gene (2) pre-S1 and (3) pre-S2. They code for surface antigen (HBsAg).
   - S region codes for the major protein (S)
   - Product of S region combines with that of adjacent Pre-S2 region to form the middle (M) protein
   - Pre-S1, Pre-S2 combines with S to code for Large (L) protein
   - The L protein is present only in the virion, while the M and S proteins are found in the circulating HBsAg particles also.
2. **C gene:** It consists of pre-C and C-regions, which code for two nucleocapsid proteins.
   - Pre-C region codes for HBeAg
   - C-region codes for HBcAg
3. **X gene:** It codes for HBxAg, which can activate the transcription of cellular and viral genes.
   - It may contribute to carcinogenesis by binding to p 53.
   - HBxAg and its antibody are elevated in patients with severe chronic hepatitis and hepatocellular carcinoma.
4. **P gene:** It is the largest gene and codes for polymerase (P) protein which has three enzymatic activities—
   1. DNA polymerase activity
   2. Reverse transcriptase activity
   3. RNase H activity

Hepatitis B Virus Mutants

Mutations in various genes of HBV can lead to emergence of mutant strains. Three types of such mutations have been identified, which are as follows:

1. Pre-core Mutants

They have defect in precore region of C gene which leads to their inability to synthesize HBeAg.

- **Viral mutation:** Though several mutations are identified; most commonly encountered is a **nonsense mutation** in the pre-C gene leading to formation of premature stop codon.
- **Geographical distribution:** Pre-core mutants have been identified in Mediterranean countries and in Europe.
- Patients infected with precore mutants may be diagnosed late and they tend to have **severe chronic hepatitis** that progresses more rapidly to cirrhosis.
- **Viral markers:** They lack HBeAg. Other viral markers are present as such.

2. Escape Mutants

The escape mutants of HBV have mutations in the S gene which leads to alteration of HBsAg.

- Mutation occurs in the immunodominant *a* antigen of HBsAg (single amino acid substitution from glycine to arginine, occurs at position 145).
- Escape mutants are observed in three situations—
  1. Infants born to HBeAg positive mothers
  2. Liver transplant recipients who underwent the procedure for hepatitis B and who were treated with a high-potency human monoclonal anti-HBs preparation.
  3. A small proportion of recipients of active and passive immunization, in whom antibody pressure may favor evolutionary change in gene coding *a* antigen.
- When these mutants are present they may pose problems in hepatitis B vaccination strategies as well as in the diagnosis of the disease.

3. YMDD Mutation

Hepatitis B virus infected patients on lamivudine therapy may develop resistance to the drug due to mutation in the YMDD locus present in the HBV reverse transcriptase region of polymerase gene.

Hepatitis B Replication (Fig. 50.4)

Replication of HBV is quite different from other DNA viruses.

- The HBV attaches to host cells by Pre-S region of HBsAg, penetrates into cytoplasm and gets uncoated to release viral DNA and polymerase.
- In the host cell nucleus, the partially dsDNA of HBV gets converted into covalently closed circular dsDNA (cccDNA) mediated by host enzymes.
- The cccDNA serves as the template for the production of HBV mRNAs and pregenomic RNA by undergoing transciption.
- HBV mRNAs translate to form various components of viral proteins (e.g. the core protein, HBcAg).
- The pregenomic RNA comes to cytoplasm and gets encapsidated by newly synthesized HBcAg.
- Within the core particle, the pregenomic RNA serves as template to form the minus strand of the DNA; mediated by the reverse transcriptase activity of the polymerase gene.
- Next, the RNA template is removed from the negative-strand DNA; mediated by the RNase H activity of the polymerase gene
- Then, the polymerase starts to synthesize the positive DNA strand, but the process is not completed.
- As a result, the dsDNA which is formed has a full-length minus-strand DNA and a variable-length (50–80%) positive-strand DNA.
- Core particles containing these dsDNA bud from pre-Golgi membranes (acquiring the envelope HBsAg) and may either exit the cell or re-enter the intracellular infection cycle.

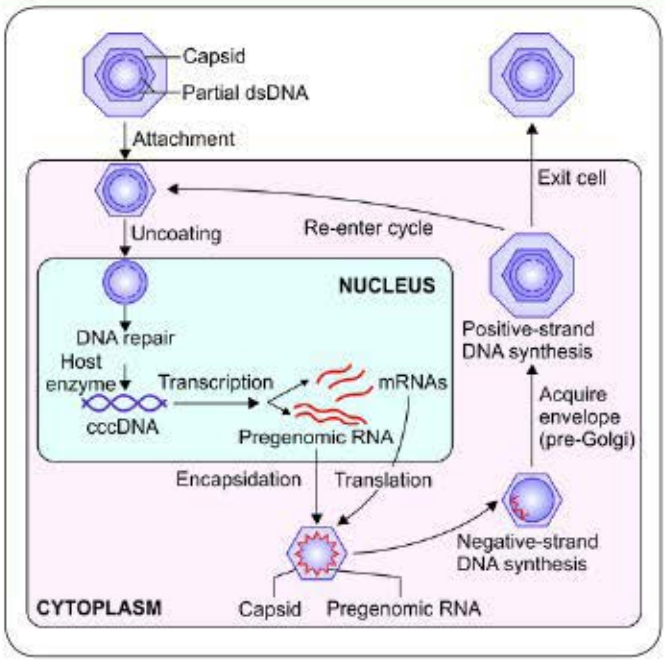

Fig. 50.4: Replication of HBV

Transmission

Hepatitis B virus transmission occurs via multiple routes.

- **Parenteral route:** In developing countries, the most common mode of transmission is via blood and blood products transfusion and needle prick injuries.
  - Transmission also occurs by inoculation during surgical or dental procedures or percutaneous inoculation via shared razors and tooth brushes.
  - HBV is more infectious than HIV and HCV. As little as 0.00001 mL of blood can be infectious.
  - Chance of transmission of HBV following a contaminated needle prick injury is nearly 30% as compared to 3% and 0.3% with HCV and HIV respectively.
- **Sexual transmission** is found to be the most common route in most developed countries; particularly homosexual males being at higher risk.
- **Vertical (perinatal) transmission:** The spread of infection from HBV carrier mothers to babies appears to be an important mode of transmission particularly in China and South East Asia.
  - Transmission occurs at any stage; in utero, during delivery (maximum risk) and during breast feeding.
  - Risk is maximum if the mother is HBeAg positive.
- **Direct skin contact** with infected open skin lesions may trasmit the virus, e.g. impetigo (especially in children).
- Although HBV can survive in mosquitoes; no transmission has been observed.

High risk groups which are more prone for acquiring infection are:

- Surgeons (maximum risk)
- Paramedical workers
- Sex workers especially homosexual males
- Recipients of blood transfusion and organ transplantation
- Drug addicts

Epidemiology

Hepatitis B virus infection occurs throughout the world; usually sporadic, but occasional outbreaks can occur in hospitals.

- **Reservoir of infection:** Humans are the only reservoir of infection who can be either cases or carriers.
  - Cases may be either inapparent or symptomatic.
  - Carriers may be temporary (harbor the virus for weeks to months) or persistent/chronic (harbor the virus for > 6 months).
- **Carriers** can also be grouped into:
  - **Simple carriers:** They are of low infectivity, transmit the virus at a lower rate. They possess low level of HBsAg and no HBeAg.
  - **Super carriers:** They are highly infectious and transmit the virus efficiently. They possess higher levels of HBsAg and also have HBeAg, DNA polymerase and HBV DNA.
- **HBV prevalence:** It is determined based on HBsAg carrier rates. There are three epidemiological patterns observed among various countries:
  1. **Type 1 pattern (low endemicity):** Carrier rate is less than 2%. It is observed in SriLanka and Nepal.
  2. **Type 2 pattern (intermediate endemicity):** Carrier rate is between 2 and 8%. It is observed in India, Bhutan, Indonesia and Maldives.
  3. **Type 3 pattern (high endemicity):** Carrier rate is more than 8%. It is observed in Bangladesh and DPR Korea.
- **Situation in the world:** Globally, chronic Hepatitis B infection occurs in about 350 million people with more than 6 lakh deaths each year.
- **Situation in India:** Overall, India accounts for the second largest burden of HBV infection, next to China.
  - India is considered to have an intermediate level of HBV endemicity (3.7% prevalence, i.e. over 40 million HBV carriers). South Indians have higher carrier rates.
  - HBV is the second most common cause of acute viral hepatitis in India after HEV.
- **Resistance:** HBV can be destroyed by hypochlorite and heat (by autoclaving).
- **Period of infectivity:** People infected with HBV are said to be infectious as long as the HBsAg is present in blood, i.e. during incubation period (a month before jaundice) up to several months thereafter (occasionally years for chronic carriers).
  - Patients become non-infectious once HBsAg disappears and is replaced by anti-HBs antibody.
  - Maximum infectivity is observed when HBe Ag is elevated in serum.
- **HBV and HIV Co-infection:**
  - It is estimated that 10% of the total HIV infected people worldwide are co-infected with HBV.
  - Although HBV does not alter the progression of HIV, the presence of HIV greatly enhances the risk of developing HBV associated cirrhosis and liver cancer.
- **Age:** The outcome (Fig. 50.5) of HBV infection depends on the age. Following HBV infection:
  - Chance of developing acute hepatitis is directly related to the age:
    - 1% (perinatal)
    - 10% (early childhood; 1–5 years of age)
    - 30% (late childhood; after 5 years of age)
  - Chance of developing chronic hepatitis or carrier state is inversely related to age:
    - 80–90% (perinatal)
    - 30% (early childhood; 1–5 years of age)
    - 5% (late childhood; after 5 years of age)
  - **Explanation:** Pathogenesis of HBV infection is immune mediated
    - Hepatocytes carrying viral antigen are subjected to natural killer cell mediated or CD8 T cell mediated cytotoxicity

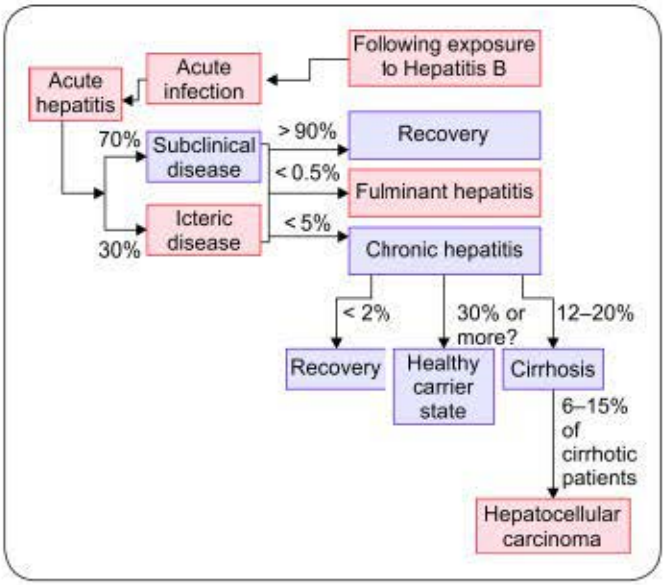

Fig. 50.5: Various outcomes of HBV infection

- Absence of an effective immune system (e.g. infants) leads to carrier state.

Clinical Manifestation

- Incubation period is about 30–180 days.
- Onset is slow and insidious
- Patients may present with subclinical infection either acute or chronic hepatitis (Fig 50.5).
- Clinically, HBV infection is indistinguishable from other hepatitis viruses; characterized by:
  - Pre-icteric phase (predominant gastrointestinal symptoms such as nausea and vomiting) followed by;
  - Icteric phase or jaundice
- Clinical outcome may be either development of carrier state or complete recovery.
- **Hepatic complications:** Very few cases may proceed to complications such as fulminant hepatitis or cirrhosis or hepatocellular carcinoma.
- **Extrahepatic complications:** During the prodromal phase, a serum sickness-like syndrome characterized by arthritis, rash, angioedema, and rarely, hematuria and proteinuria may develop in 5–10% of patients. This is due to immune complex deposition.

LABORATORY DIAGNOSIS — Hepatitis B virus

- **Antigen markers:** HBsAg, HBeAg and HBcAg
- **Antibody markers:** Anti-HBs, Anti-HBe and Anti-HBc
- **Molecular markers:** HBV DNA
- **Non-specific markers:** Elevated liver enzymes and serum bilirubin

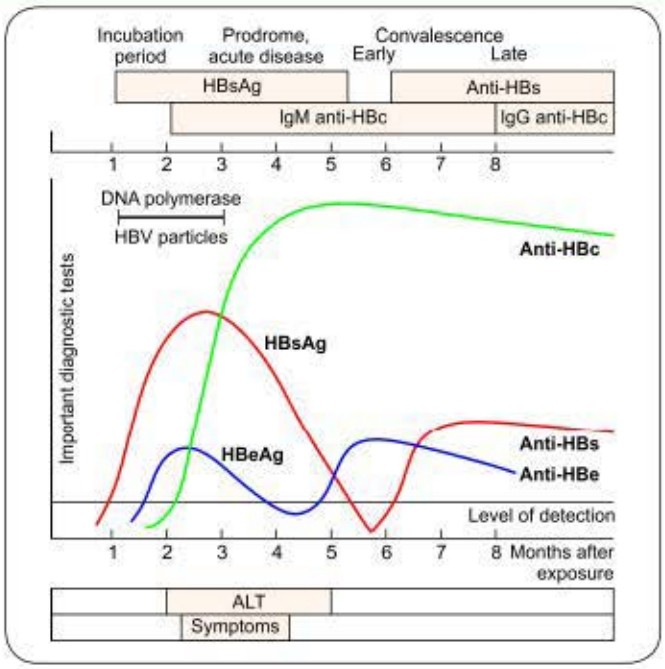

Fig. 50.6: Serological markers of hepatitis B virus in various stages of hepatitis B virus infection

Laboratory Diagnosis

Viral Markers of HBV Infection

Definitive diagnosis of hepatitis B depends on the serological demonstration of the viral markers (Fig. 50.6 and Table 50.2, laboratory diagnosis synopsis box).

The most useful detection method for HBV antigens and antibodies is ELISA although various rapid test formats such as immunochromatographic test (ICT) are also

TABLE 50.2: Interpretation of HBV sero-markers

HBsAg	Anti-HBs	Anti-HBc	HBeAg	Anti-HBe	Interpretation
+	–	–	–	–	Early acute hepatitis (Incubating)
+	–	IgM	+	–	Acute hepatitis B, high infectivity
+	–	IgG	+	–	▪ Chronic hepatitis B, high infectivity ▪ Super carrier (If asymptomatic, normal liver enzymes)
+	–	IgG	–	+	▪ Chronic hepatitis B, low infectivity ▪ Simple carrier(If asymptomatic, normal liver enzymes)
+	–	IgG	–	–	Precore–mutant hepatitis B
–	+	+	–	+/–	Recovery
–	–	IgG	–	–	▪ Remote infection (common) ▪ False positive immunoassay (rare)
+	+	IgG	+/–	+/–	▪ HBsAg of one subtype and heterotypic anti–HBs (common, seen in 10–20%) ▪ Process of seroconversion from HBsAg to anti– HBs (rare)
–	+	–	–	–	Post-vaccination
–	–	IgM	+/–	+/–	Time period between appearance of anti-HBs antibody and disappearance of HBSAg

available. Viral DNA can be detected by PCR (Polymerase chain reaction); but quantified by real time PCR. HBV does not grow in any conventional culture system.

Hepatitis B Surface Antigen (HBsAg)

HBsAg is the first marker to be elevated following infection; appears within 1–12 weeks (usually between 8 and 12 weeks of infection).

- It appears during incubation period; 2–6 weeks before the biochemical and clinical evidence of hepatitis.
- Presence of HBsAg indicates onset of infectivity (i.e. patient is capable of transmission of HBV).
- It remains elevated in the entire duration of acute hepatitis; becomes undetectable 1–2 months after the onset of jaundice
  - However, it persists rarely beyond 6 months if the disease progresses to chronic hepatitis or in carrier state.
- HBsAg is used as an epidemiological marker of hepatitis B infection (i.e. to calculate prevalence of infection).

Hepatitis B Pre-core Antigen (HBeAg) and HBV DNA

HBeAg and HBV DNA appear concurrently with or shortly after appearance of HBsAg in serum.

- They are the markers of—
  - Active viral replication
  - High viral infectivity (i.e. high transmission rate)
- However, these markers can be present in either acute, chronic or carrier state; hence they cannot differentiate between these stages. Their presence just indicates that the virus is actively multiplying, which could be either:
  - Acute active hepatitis
  - Chronic active hepatitis
  - Or a carrier in whom HBV is actively multiplying and is highly infectious (such carriers are called **super carriers**).

Hepatitis B Core Antigen (HBcAg)

- HBcAg is a hidden antigen due to its surrounding HBsAg coat. It is also non-secretory in nature; hence, it cannot be detected in blood.
- However, HBcAg may be detected in hepatocytes by immunofluorescence test.

Anti-HBc IgM (Hepatitis B Coreantibody)

Anti-HBc IgM is the first antibody to be elevated following infection.

- It appears within first 1–2 weeks after the appearance of HBsAg and lasts for 3–6 months.
- Its presence indicates acute hepatitis B infection.
- It is probably the only marker (sometimes anti-HBcIgG) present during the period between appearance of anti-HBs antibody and disappearance of HBsAg.

Anti-HBc IgG (Hepatitis B Core Antibody)

Anti-HBc IgG appears in late acute stage and remains positive indefinitely whether the patient proceeds to—

- **Chronic stage** (with persistence of HBsAg, symptomatic and elevated liver enzymes)
- **Carrier state** (with persistence of HBsAg, but asymptomatic)
- Recovery (appearance of anti-HBs antibody)

It can also be used as epidemiological marker of HBV infection.

Anti-HBe (Hepatitis B Precore Antibody)

- Anti-HBe antibodies appear after the clearance of HBeAg and remain elevated for variable period.
- Its presence signifies diminished viral replication and decreased infectivity.

Anti-HBs (Hepatitis B Surface Antibody)

It appears after the clearance of HBsAg and remains elevated indefinitely.

- Its presence indicates recovery, immunity and non-infectivity (i.e. stoppage of transmission).
- It is also the only marker of hepatitis B vaccination.

TREATMENT — Hepatitis B virus

- In acute hepatitis B infection among previously healthy adults, recovery occurs in 99%; therefore, antiviral therapy is unnecessary.
- Specific antiviral drugs are indicated in stages of fulminant hepatitis or severe chronic hepatitis. Recommended drugs are:
  - Pegylated interferon
  - Nucleoside/nucleotide analogues—lamivudine, adefovir, entecavir, telbivudine and tenofovir.

Prophylaxis

Active Immunization (Hepatitis B Vaccine)

Hepatitis B vaccine is a recombinant subunit vaccine.

- The surface antigen (HBsAg) is used as vaccine candidate which is prepared in Baker's yeast by DNA recombinant technology by cloning the S gene into the yeast chromosome.
- **Route of administration:** Vaccine is administered by intramuscular route over deltoid region (in infant-anterolateral thigh).
- **Dosage:** 10–20 µg/dose (half of the dose is given to children below 10 years).
- **Schedule:**
  - Recommended schedule for adults: Three doses are given at 0,1 and 6 months.
  - Under national immunization schedule: It is given at 6, 10, 14 weeks (along with DPT vaccine). Additional

dose at birth may be given in areas with prevalence of HBV more than 8%
  - Minimum interval between the doses—4 weeks
- **Marker of protection:** Recipients are said to be protected if they develop seroconversion with an anti-HBsAg antibody titer of more than 10 IU/mL.
- **Non/low responders:** About 5–10% of individuals mount an impaired immune response following vaccination. They may be either
  - Non responders (do not show seroconversion) or;
  - Low responders (seroconversion occurs slowly)
- Seroconversion occurs in about 95% of infants, children and young adults. However, among older people (>60 years), the protection is about 65–75% only.
- Protection may last for about 15 years or even longer.
- Booster doses are needed after 5 years especially to high-risk group if the antibody titer falls below 10 IU/mL.
- Newer vaccine containing whole HBsAg (i.e. product of *Pre S1 + Pre S2 + S genes*) is under development which may provide a better seroconversion.

Passive Immunization (Hepatitis B Immunoglobulin or HBIG)

- **Indications:** HBIG is used in the following situations where an **immediate protection** is warranted.
  - Acutely exposed to HBsAg positive blood, e.g. surgeons, nurses, laboratory workers.
  - Sexual contact of acute hepatitis B patients
  - Neonates borne to hepatitis B carrier mothers
  - Post liver transplant patients who need protection against HBV infection

  Following accidental exposure, HBIG should be started immediately (ideally within 6 hours, but not later than 48 hours).
- **Recommended dose** is **0.05-0.07 mL/kg** body-weight, two doses of HBIG should be given 30 days apart.
- HBIG gives short term passive protection which lasts for about 100 days. Since the median incubation period is less than 100 days, two doses given one month apart should suffice.

Combined Immunization

Combined immunization with **HBIG** and **vaccine** is more efficacious than HBIG alone. It is recommended for **neonates** born to HBV infected mother, where a single injection of 0.5 mL of HBIG is given to the neonate immediately after the birth, followed by full course of vaccine (the first dose being given within 12 hours of birth).

The guideline for post-exposure prophylaxis is as follows:

- If the exposed person is vaccinated and the antibody titer is protective (i.e. >10 IU/mL) no further treatment is needed:
- If the exposed person is vaccinated and the titer is not protective (i.e. < 10 IU/mL):
  - HBIG should be started immediately.
  - Vaccine: Single dose should be given within 7 days of exposure.
- If the exposed person is not vaccinated: HBIG and full course of vaccine (3 doses) are needed.

General Prophylactic Measures

- Screening of blood bags, semen and organ donors.
- Following safe sex practices (e.g. using condoms, avoiding multiple sex partners).
- Following safe injection practices—use of the disposable syringes and needles.
- Following safe aseptic surgical practices
- Health education

HEPATITIS C VIRUS

Hepatitis C virus (HCV) is the common cause of post-transfusion hepatitis in developing countries. It was discovered in 1989 and first labelled as "non-A, non-B hepatitis virus while performing the experiments in chimpanzees.

Morphology

Hepatitis C virus is classified under family Flaviviridae, genus *Hepacivirus*.

- It is spherical, 60 nm size and enveloped.
- **Nucleic acid:** It contains a positive sense ssRNA.
- **Proteins:** HCV possesses—
  - Three structural proteins: The nucleocapsid core protein C; two envelope glycoproteins (E1 and E2).
  - Six nonstructural (NS) proteins: NS1 (membrane protein p7 which functions as an ion channel), NS2, NS3, NS4A, NS4B, NS5A, and NS5B (Fig. 50.7).

Genetic Diversity of HCV

Hepatitis C virus displays diversity in the RNA genome that occurs because of high rates of mutations seen in the virus.

- **Genotypes:** HCV is divided into six major genotypes or clades, which differ from each other by 25–35% in their RNA sequence.
- **Subtypes:** Genotypes are further divided into more than 100 subtypes, which differ from each other by 15–25% in their RNA nucleotide sequence. Within any given patient, the subtypes of HCV circulate as complex closely related viral population known as **quasispecies**.
- The **E2 envelope protein** is the most variable region of the entire HCV genome followed by the non-structural proteins (especially, NS5B encoded RNA polymerase); hence they are more prone to undergo mutations.

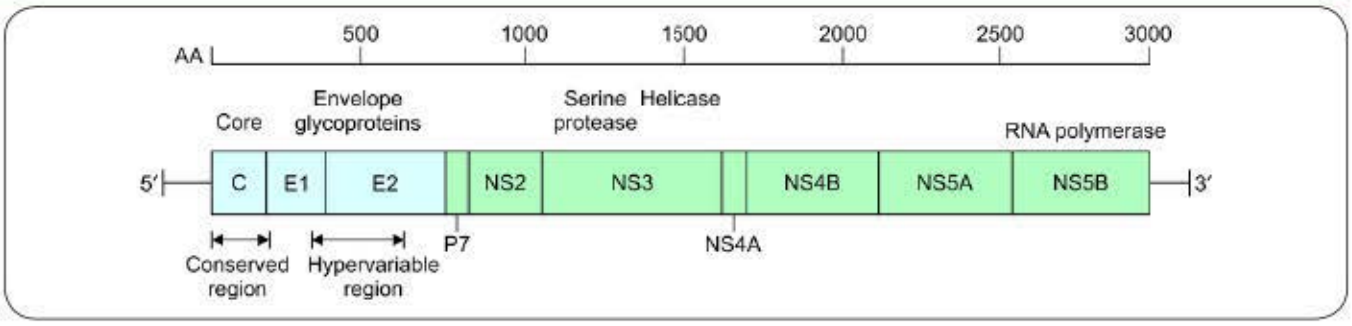

Fig. 50.7: Genome of Hepatitis C virus

- Unfortunately, E2 protein happens to be the target against which most of the neutralizing (protective) antibodies are produced.
- Thus, diversity in the gene coding E2 protein enables the emergent mutant virus strains to escape from host's humoral immunity, which in turn can result in:
  - Establishment of chronic infection
  - Failure of development of effective vaccine
- HCV genotypes do not vary in clinical severity but they vary in their epidemiological distribution:
  - Genotype 1 is the most common type, distributed worldwide
  - Other genotypes are geographically restricted, e.g. genotype 4 (Egypt); genotype 5 (South Africa) and genotype 6 (Hong Kong).
  - In India, genotypes 1 and 3 are more prevalent.
- The genotypes also vary in their susceptibility to antiviral drugs.Patients with genotype-1b respond poorly to therapy than other genotypes.

Transmission

Various modes of transmission of HCV are as follows:

- **Parenteral:** HCV is most commonly transmitted through exposure to infectious blood:
  - Recipients of contaminated blood transfusions, blood products or organ transplantations.
  - Contaminated needles and sharps pricks
  - Injection drug users
- **Vertical transmission** from infected mother to fetus may occur but at much lower rate (6%) than that of HBV (20%).
- **Sexual transmission** (rare)

Hepatitis C virus **doesn't spread** through breast milk, food or casual contacts including hugging or kissing.

Clinical Manifestations

Incubation period is about 15–160 days (average 50 days). Following an infection with HCV:

- **Acute hepatitis:** About 20% of people develop acute hepatitis; characterized by symptoms similar to that of other hepatitis viruses described earlier.
- **Chronic disease:** About 75–80% directly develop chronic disease; out of which—
  - 60–70% develop chronic hepatitis
  - 5–20% develop cirrhosis
  - 1–5% develop hepatocellular carcinoma. (HCV accounts for 25% of total liver cancer patients)
- **Extrahepatic manifestations:** Due to deposition of circulating immune complexes (composed of HCV antigens and their antibodies) in extra hepatic sites, various manifestations can set in such as:
  - Mixed cryoglobulinemia
  - Glomerulonephritis
  - Arthritis and joint pain

Epidemiology

Hepatitis C virus infection occurs worldwide. Every year, 3–4 million people are infected with HCV with more than 3.5 lakhs deaths.

Population prevalence rate:

- About 3% of the world population has been infected with HCV worldwide with more than 170 million chronic carriers.
- Higher prevalence rates have been documented from Africa (up to10%) followed by South America and Asia.
- In India, the prevalence is about 1%

Laboratory Diagnosis

Serum Antibody Detection

Anti-HCV antibodies appear in about 8–9 weeks after exposure. It is detectable in more than 95% of chronic cases; however; in acute hepatitis antibodies are variably present, detectable in 50–70% of patients; in the remaining patients, the antibodies appear after 3–6 weeks (Fig. 50.8).

Third-generation ELISAs are the most popular assays currently available, which employ the antigens from

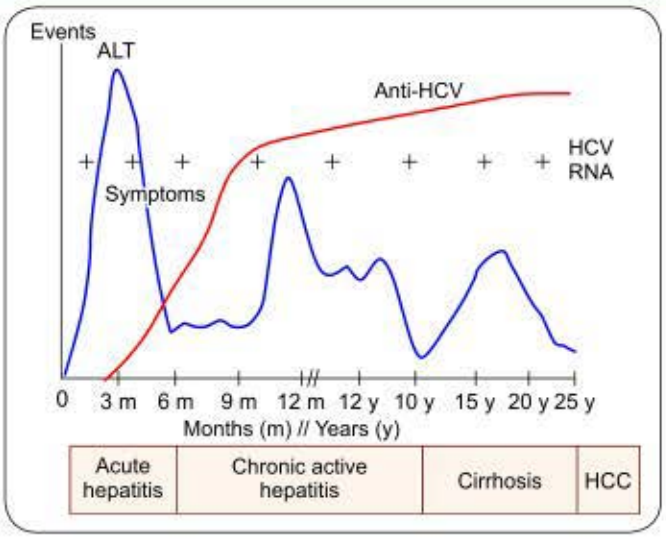

Fig. 50.8: Course of markers in hepatitis C virus infection

Abbreviations: ALT, alanine transminase; HCC, hepatocellular carcinoma

the core, NS3, NS4, and NS5 regions, to detect anti-HCV antibodies:

- **Acute diagnosis:** Anti-HCV (C33c, C22-3, NS5) are detected.
- **Chronic diagnosis:** Anti-HCV (C100-3, C33c, C22-3, NS5) are elevated.

HCV RNA

Heatitis C virus RNA detection is the most sensitive method and considered as the "gold standard test" for the diagnosis of hepatitis C. HCV RNA can be detected even before rise of liver enzymes and HCV antibodies. Methods available to detect HCV RNA are:

- **Branched-chain DNA (bDNA) assay:** It is less sensitive with a detection limit of 10^3IU/mL.
- **Reverse transcriptase PCR:** More sensitive, detection limit of 10–10^2IU/mL
- Transcription mediated amplification (TMA)
- **Real time RT PCR:** is the most sensitive test among all and can be used for quantification. However, it is noted that viral load is not a reliable marker of disease severity or prognosis, but is helpful in predicting response to therapy.

TREATMENT — Hepatitis C virus

The most recommended regimen is combined therapy with pegylated interferon plus ribavirin.

- Treatment should be started within 2–3 months after the onset of disease and continued for 24 weeks.
- This regimen gives sustained response rate of up to 50% in patients with chronic hepatitis C infection.

Predictors of Treatment Response

- **Genotypes:** People with HCV genotype 1b show the worst prognosis among all genotypes.
- **Viral RNA load:** Higher the viral load (> 800,000 IU/mL), worse is the prognosis.
- Interleukin 28 B is a strong inducer of interferon-α.
  - People possessing a subtype of IL 28B (called CC genotype), produce a stronger immune response to HCV infection by inducing IFN-α release; hence have a better outcome.
  - Caucasians and African Americans lack **CC genotype**, hence show a poor treatment response than that of Asians.
- Metabolic disorders such as insulin resistance, obesity reduce the chance of responding to HCV therapy.

Prevention

There is no effective vaccine available for HCV. General prophylactic measures are essentially same as that for HBV.

HEPATITIS D VIRUS

Hepatitis D virus is a defective virus; cannot replicate by itself; depends on Hepatitis B virus for its survival.

Morphology

Hepatitis D virus is taxonomically unclassified though resembles viroids. It is small in size (35 nm), consisting of:

- Circular, negative-sense ssRNA
- Protein coat made up of single protein called **hepatitis D antigen (HDAg)**
- Surrounded by envelope protein derived from HBsAg from hepatitis B virus; hence it is called **defective virus**.

Transmission

Transmission is similar to that of HBV and HCV. Parenteral route is the most common mode; followed by sexual and vertical routes.

HDV and HBV Association

The association of HDV with HBV is of two types (Table 50.3):

- **Co-infection:** It occurs when a person is exposed simultaneously to serum containing both HDV and HBV.
  - Hepatitis B virus infection sets in first so that HBsAg becomes available for HDV.
  - This is usually a transient and self-limited condition; clinically indistinguishable from acute hepatitis B infection.
  - It rarely progresses to chronic stage; at a rate similar to that of HBV infection alone.
  - Vaccination against hepatitis B can prevent against HDV.
- **Super-infection:** It occurs when a chronic carrier of HBV is exposed to serum containing HDV. This results in disease 30–50 days later which may have two phases

Contd...

TABLE 50.3: Differences between Hepatitis D and Hepatitis B virus (HDV-HBV) co-infection and super-infection

Features	Co-infection	Super-infection
Definition	HBV and HDV infection occurs simultaneously	HDV infection occurs to a carrier of HBV
Patient status	Healthy	HBV carrier
Risk of development of:		
Fulminant disease	More than that of HBV alone	More than that of co-infection
Chronic hepatitis	Rare	Much greater
Cirrhosis	Rare	More
HCC	Rare	More
Mortality	Rare	>20%
Diagnosis	▪ HBsAg ▪ Anti-HBc (IgM) ▪ Anti-HDV (IgM) ▪ HDV RNA	▪ HBsAg ▪ HBeAg ▪ Anti-HBc (IgG) ▪ Anti-HDV - In acute phase IgM In Chronic phase-IgG and IgM ▪ HDV RNA

Abbreviation: HCC, hepatocellular carcinoma

Contd...

- **Acute phase** in which HDV replicates actively with high transaminase levels with suppression of HBV.
- **Chronic phase** in which HDV replication decreases, HBV replication increases, transaminase levels fluctuate, and the disease progresses to cirrhosis and hepatocellular carcinoma (HCC). Mortality rate is much higher (>20%).

Laboratory Diagnosis

- **In co-infection:** IgM against both HDAg and HBcAg are elevated, although IgM anti-HDV appears late and is frequently short-lived.
- **In super-infection:** As HBV infection is already established as carrier, IgG anti-HBc will be detected. Anti-HDV would be IgM type initially; but as patient progresses to chronic state, mixture of IgM and IgG would persist for months or longer.
- Anti HBc antibody is the key to differentiate between co-infection and super-infection.
  - **IgM anti HBc + IgM anti-HDV:** Indicates co-infection.
  - **IgG anti HBc + mixture of IgM and IgG anti-HDV:** Indicates super-infection.
- HDV RNA is detectable in the blood and liver just before and in the early days of acute phase of both co-infection and super-infection.
- HBeAg, the marker of active HBV replication may be present in super-infection.

Epidemiology

Globally, about 15 million people are infected with HDV (about 5% of 350 million of HBV infected persons).

Hepatitis D virus infection occurs worldwide, but prevalence varies greatly. Surprisingly, HDV is not prevalent in Southeast Asia including India; where HBV carriers are maximum.

Two epidemiologic patterns have been identified:

1. **In endemic areas**, such as Mediterranean countries (Northern Africa, Southern Europe,and Middle East) HDV is endemic among persons with hepatitis B and is transmitted predominantly by non-percutaneous means, especially by close personal contact.
2. **In non-endemic areas**, such as the USA and Northern Europe, HDV infection is confined to persons frequently exposed to blood and blood products, primarily injection drug users and hemophiliacs who are infected with HBV.
   - HDV infection can be introduced into a non-endemic population through IV drug users or by migration of persons from endemic to non-endemic areas.
   - Introduction of HDV into non-endemic areas where HBV infection is common may lead to explosive outbreaks of severe hepatitis with high mortality.

TREATMENT **Hepatitis D virus**

Patients with HDV infection can be treated with IFN-α. Treatment for HBV should be continued as described earlier.

Prevention

Vaccination for HBV can also prevent HDV infection. General prophylactic measures are essentially same as that for HBV.

HEPATITIS E VIRUS

Hepatitis E virus (HEV) causes an enterically transmitted hepatitis primarily occurring in young adults which occurs as epidemics in developing countries.

Morphology

Although HEV resembles caliciviruses, taxonomically it is distinct from them; hence has been assigned to a unique genus, *Hepevirus*, under the family Hepeviridae.

- HEV is small (30–32 nm size), non-enveloped with icosahedral symmetry.
- It contains positive-sense, ssRNA and a specific antigen (HEV-Ag).

- **Genotypes:** HEV has single serotype; however, five genotypes exist in nature, which differ up to 25% in their RNA sequence.
  - Only four genotypes have been detected in humans
  - Genotypes 1 and 2 appear to be more virulent
  - Genotypes 3 and 4 are more attenuated and account for subclinical infections.

Clinical Manifestation

Incubation period is about 14–60 days (average 40 days).

- Most of the patients present as self-limiting acute hepatitis lasting for several weeks followed by complete recovery.
- Fulminant hepatitis may occur rarely in 1–2% of cases; except for the **pregnant women** who are particularly at higher risk **(20%)** of developing fulminant hepatitis.
- There is no chronic infection or carrier state.

Epidemiology

Hepatitis E virus is a zoonotic disease affecting various animals such as monkeys, cats, pigs and dogs

- **Transmission:** It is Fecal-orally transmitted via sewage contamination of drinking water or food.
- **Epidemics** of HEV infections have been reported primarily from India, Asia, Africa and Central America; HEV is the most common cause of acute hepatitis in this zone.
- Other parts of the world (temperate climate), HEV is uncommon and usually occurs in travelers coming from endemic zone.
- The first major epidemic of HEV was reported from New Delhi (1995) where 30,000 people were affected due to sewage contamination of the city's drinking water supply following a flood that occurred in Yamuna river. China reported more than 1 Lakh cases of jaundice during an outbreak in 1986–88.
- **In India,** HEV infection accounts for maximum (30-60%) cases of sporadic acute hepatitis.
- Though it resembles to HAV, the striking features that differentiate HEV from that of HAV are:
  - Secondary attack rate (transmission from infected persons to their close contacts) is rare (1–2%) in HEV, compared to 10–20% in HAV.
  - **Age:** Young adults (20–40 years age) are commonly affected in HEV compared to children in HAV.

Laboratory Diagnosis

- **HEV RNA** (by reverse transcriptase PCR) and **HEV virions** (by electron microscopy) can be detected in stool and serum even before the onset of clinical illness
- **Serum antibody** detection by ELISA:
  - **IgM anti-HEV** appears in serum at the same time with the appearance of liver enzymes and indicates acute infection.
  - **IgG anti-HEV** replaces IgM in 2 to 4 weeks (once the symptoms resolve) and persists for years; indicates recovery or past infection.

TREATMENT **Hepatitis E virus**

There is no specific antiviral drug available.

Prevention

General measures for prevention and containment of infection are the same as described for HAV. China has produced and licensed the first HEV vaccine called **'HEV 239'** using recombinant HEV proteins. However, it is not yet available globally.

HEPATITIS G VIRUS

Hepatitis G virus (HGV, also referred to as GB virus C) was discovered in 1995.

- It is related to Hepatitis C virus, belongs to family Flaviviridae, under the genus *Pegivirus*.
- HGV is transmitted by contaminated blood or blood products, or via sexual contact.
- Hepatitis G virus is wrongly named as it is not hepatotropic and does not cause hepatitis. Instead, it replicates in the bone marrow and spleen; however, it is not associated with any known human disease so far.
- It has been classified into six genotypes, each has its own geographical distribution.
- **HIV co-infection:** HGV commonly co-infects people infected with HIV (prevalence 35%); but surprisingly this dual infection is **protective against HIV** and patients survive longer.

EXPECTED QUESTIONS

I. Essay:

1. Raju, a 40-year-old male presented with history of loss of appetite, malaise and jaundice of 2 months duration. On examination, there was icterus, hepatomegaly and tenderness in the right hypochondriac region. He gave a history of blood transfusion in the past. On laboratory examination, he was found to be positive for HBsAg.
   a. What is the most probable etiological diagnosis?
   b. Discuss in detail about the various laboratory diagnosis of this condition?
   c. How will you prevent the transmission of this infection?

II. Write short notes on:

a. Hepatitis A virus
b. Laboratory diagnosis of hepatitis C virus
c. Hepatitis D virus
d. Hepatitis E virus

III. Multiple Choice Questions (MCQs):

1. Perinatal Hepatitis B transmission is maximum in:
a. 1st trimester b. 2nd trimester
c. 3rd trimester d. During delivery

2. Which Hepatitis virus is associated with highest mortality in pregnancy?
a. Hepatitis A b. Hepatitis B
c. Hepatitis C d. Hepatitis E

3. Hepatitis virus that spreads by fecal-oral route:
a. Hepatitis A b. Hepatitis B
c. Hepatitis C d. Hepatitis D

4. Which is known as Australia antigen?
a. HBsAg b. HBeAg
c. HBcAg d. HBV DNA

5. Acute hepatitis B is best diagnosed by:
a. HBsAg b. HBeAg
c. IgM Anti HBc antibody d. HBcAg

6. Hepatitis B vaccine should be given as per which schedule:
a. 0, 1, 6 days b. 0, 1, 6 weeks
c. 0, 1, 6 months d. 0, 1, 6 years

Answers

1. d **2.** d **3.** a **4.** a **5.** c **6.** c

CHAPTER 51

Oncogenic Viruses

Chapter Preview

- Classification
- Viral oncogenesis
- Oncogenic RNA viruses
- Oncogenic DNA viruses

CLASSIFICATION

Viruses account for 15% of all human malignancies. There are several oncogenic viruses found worldwide, which include the agents of two major malignancies—Human papillomavirus causing carcinoma cervix and Hepatitis B virus causing liver cancer (Table 51.1).

In addition to the list of human oncogenic viruses given in Table 51.1, there are certain other viruses that can cause cancers in animals but not in humans such as:

- Poxviruses such as Yaba virus and rabbit fibroma viruses
- Adenoviruses (types 12, 19, 21) produce sarcomas in newborn rodents
- Herpesviruses
  - Marek's disease virus
  - Lucke's frog tumor virus
- Animal retroviruses:
  - Avian leukosis viruses (e.g., Rous sarcoma virus)
  - Murine leukosis viruses
  - Murine mammary tumor virus
  - Leukosis sarcoma virus of various animals

VIRAL ONCOGENESIS

Before understanding the detailed mechanism of viral oncogenesis, knowledge about oncogenes and normal host genes regulating cellular growth is essential.

Oncogenes

Oncogenes encode certain proteins (oncoproteins) that trigger the transformation of normal cells into cancer cells.

- **V-onc (viral oncogenes):** Oncogenes present in the viral genome are called as **viral oncogenes (V-onc)**. They are essential for the replication of the virus. Viral oncogenes are expressed only by certain retroviruses (called as **acutely transforming retroviruses**).

TABLE 51.1: Human oncogenic viruses and associated malignancies

Virus Family	Human Cancer
DNA Oncogenic Viruses	
Papillomaviridae/ Polyomaviridae	
Human papillomaviruses	▪ Cervical carcinoma ▪ Other genital tract carcinoma • Anal • Vulval/vaginal • Penile ▪ Esophageal carcinoma ▪ Laryngeal carcinoma ▪ Oropharyngeal carcinoma
Merkel cell virus	▪ Merkel cell carcinoma of skin
Herpesviridae	
Epstein Barr virus	▪ Burkitt's lymphoma ▪ Hodgkin's disease ▪ Nasopharyngeal carcinoma ▪ B cell lymphoma
Human herpesvirus-8	▪ Kaposi's sarcoma ▪ Castleman's disease ▪ Primary effusion lymphoma
Hepadnaviridae	
Hepatitis B	Hepatocellular carcinoma
RNA Oncogenic Viruses	
Retroviridae	
HTLV-I	Adult T cell leukemia/lymphoma
HIV	AIDS-related malignancies
Flaviviridae	
Hepatitis C	Hepatocellular carcinoma

Note: The association of Herpes simplex virus-2 with cervical cancer and Cytomegalovirus with prostate cancer have not been proved yet. Molluscum contagiosum virus is not an oncogenic virus as the lesion produced (molluscum contagiosum) is a benign condition.

- **C-onc (cellular oncogenes):** They are the cellular counter part of viral oncogenes present in the cancer cells.
- **Proto-oncogenes:** They are the cellular counter part of viral oncogenes present in the normal host cells.

Genes Regulating Host Cell Growth

There are four categories of genes present in the host cell, which regulate the cellular growth and proliferation. Defect in any of these regulatory genes would lead to transformation of the normal host cells into abnormal tumor cells.

1. **Proto-oncogenes:** They promote the host cell growth and proliferation that are essential for life. However, over activation of proto-oncogenes may lead to transformation of host cells.
2. **Anti-oncogenes or tumor suppressor genes**: They continuously check cellular growth and proliferation, and supress any abnormal proliferation of cells. Inactivation of tumor suppressor genes permits the abnormal event to occur resulting in cell transformation.
3. **Apoptosis-regulatory genes:** They control the programmed cell death by either upregulating or downregulating apoptosis depending on the requirement. Hence, they may act as proto-oncogenes or tumor suppressor genes. Mutations in apoptosis-regulatory genes are another mechanism by which the cellular transformation is accelerated.
4. **DNA repair genes:** They are the normal host genes that repair any mutations occurring during the cell growth. Failure of DNA repair genes lead to inability to repair the damaged DNA and may lead to persistent mutation.

Events that Must Occur Before Oncogenesis

- **Establishing persistent infection:** Prolonged interaction between the tumor virus and the host cell is essential for oncogenesis to develop and this is possible only when the tumor virus establishes a long-term persistent infection in host cells.
- **Evades host immune response:** Host immune response plays an important role in viral clearance. The tumor virus follows various evasion mechanisms to bypass the host immune response, which are as follows—
  - By restricting the expression of viral genes which go unnoticed by the immune cells [e.g., Epstein Barr virus (EBV) in B cells].
  - Infecting the sites that are relatively inaccessible to immune responses [e.g., human papillomavirus (HPV) infecting epidermis].
  - Undergoing mutation of certain genes that allows the virus to escape from the host cellular and humoral responses (e.g. HIV).
  - Infection and suppression of essential immune cells (e.g. CD4 T cell by HIV).
- **Immunosuppression** of the host allows the cancer cells to proliferate and escape the host immune response. Immunosuppressed organ transplant recipients and HIV-infected individuals are at increased risk of EBV and HPV associated malignancies.
- **Host cell susceptibility**: Host cells may be permissive or non-permissive for replication of a given virus.
  - Permissive cells support viral growth and replication of a progeny virus; non-permissive cells do not.
  - Non-permissive cells refer to the host cells that either do not have surface receptors for viral attachment or do not support the viral replication or the release of virus progeny.
  - Host cells permissive for one virus may be non-permissive for another.
  - Though oncogenicity can occur both in permissive and non-permissive cells, but the risk is more when a non-permissive cell is infected by a tumor virus as the virus tries different ways to maintain its survival in a non-permissive cell and by doing so it may undergo some changes, which makes the cell immortal.
  - This holds true especially for DNA tumor viruses. In a permissive cell, the DNA tumor viruses are released by host cell lysis. Hence the DNA tumor viruses are not oncogenic to a permissive cell, unless the viral replicative cycle that normally results in death of the host cell is blocked in some way; and grow indefinitely.
  - In contrast, RNA tumor viruses do not cause cell lysis, hence they can be oncogenic to both permissive and non-permissive cells.
- **Retention of viral nucleic acid inside the host cells** is essential to maintain a stable genetic change that occurs in a tumor cell.
  - The DNA copies of DNA tumor viruses are integrated within the host cell chromosome.
  - RNA of retroviruses gets reverse transcribed into DNA
  - Hepatitis C virus is an exception, its RNA is neither reverse transcribed, nor integrated into the host chromosome; but are maintained in the tumor cells.

Mechanism of Viral Oncogenesis

Viral oncogenesis is a complex and multistep process requiring prolonged time (years to decades) and occur only in a small percentage of the infected individuals. There are multiple oncogenic events that take place to transform the host cells into cancer cells. Viruses contribute to only a portion of those oncogenic events. In addition, other factors are necessary such as host immunity and host genetic susceptibility, etc.

Oncogenic viruses transform the host cells into tumor cells mainly by two broad mechanisms (see the box below).

1. **Direct-acting oncogenic viruses**: Certain animal retroviruses (called as **acute transforming retroviruses**) possess viral oncogenes (*V-onc*), which they directly insert into the host cell chromosomes.
2. **Indirect-acting oncogenic viruses:** Most of the human oncogenic viruses possess certain transforming genes, which they insert into the host DNA leading to altered expression of pre-existing cellular genes (which regulate host cell growth) such as:
   - Proto-oncogenes
   - Tumor suppressor gene
   - Apoptosis regulatory genes
   - DNA repair genes

ONCOGENIC RNA VIRUSES

Retrovirus

Retroviruses possess two copies of ssRNA that get reverse transcribed to DNA (proviral DNA) and get inserted into host chromosome

- The proviral DNA of any retrovirus contains three important genes—*gag*, *pol*, and *env* in that order from the 5′ to the 3′ end with long terminal repeat (LTR) sequences present at either ends (Fig. 51.1).
- The LTRs exert regulatory control on the provirus gene functions and are linked directly to the host DNA.
- In addition, certain retroviruses possess additional genes. The acutely transforming oncogenic retroviruses possess viral oncogenes (*V.onc*). The slow transforming oncogenic retroviruses possess additional regulatory gene (e.g., *tax* gene for HTLV-1 and *tat* gene for HIV).
- Oncogenic retroviruses belong to exogenous type; (i.e. spread horizontally between host cells). Endogenous retroviruses spread vertically from parent host cells to offspring) and they are mostly non-pathogens.

Oncogenicity of HTLV-I

Oncogenicity of HTLV-I are locked in the *tax* gene. It is transcription activator gene, essential for viral replication. At the same time, it modulates the host cell functions as well.

Oncogenic Retroviruses

They are classified into two groups:

1. ***Acute transforming or direct acting retroviruses:*** They are certain animal retroviruses (e.g., Rous sarcoma virus) that carry **viral oncogene** which they directly insert into host chromosome.
   - They are highly oncogenic and cause malignancy faster (within weeks or months).
   - They can cause different types of malignancies such as, sarcoma, carcinoma, leukemia.
   - They are capable of transforming cells in culture as well.
   - **Replication defective:** Most acute transforming retroviruses are unable to replicate normally because the viral oncogene replaces some of the essential genes for viral replication. They require a standard helper retrovirus to replicate in host cells. Rous sarcoma virus is an exception as it is **replication competent**, contain full-length genome and replicate normally in the host cells.
2. ***Slow transforming or indirect acting retroviruses:*** Most human oncogenic retroviruses, such as HTLV-I are slow transforming viruses.
   - They are **replication competent**, but replicate slowly.
   - Require a long latent period to develop malignancy.
   - Viral genome can insert anywhere in the host chromosomes randomly and not necessarily adjacent to proto-oncogenes
   - **Low oncogenic potential:** They do not have viral oncogenes, but possess an additional regulatory gene (e.g., *tax* gene for HTLV-I).
   - They have restricted tissue tropism for malignancies; induce malignant change only of blood cells.
   - They do not transform cultured cells.

- *Tax* gene is capable of activating the transcription of several cellular genes involved in T cells proliferation. These include:
  - Genes coding interleukin-2 (IL-2) and its receptor
  - Gene for myeloid growth factor, granulocyte-macrophage colony-stimulating factor.
- **Inhibit cell growth cycle:** *Tax* protein inactivates the cell cycle inhibitor p16/INK4a and activates cyclin D (a cell cycle enhancer), thus promoting the host cell growth cycle by accelerating the transition between G_1 and S phase.
- *Tax* gene activates nuclear factor κβ (NF-κβ), a transcription factor that regulates certain host anti-apoptotic genes.

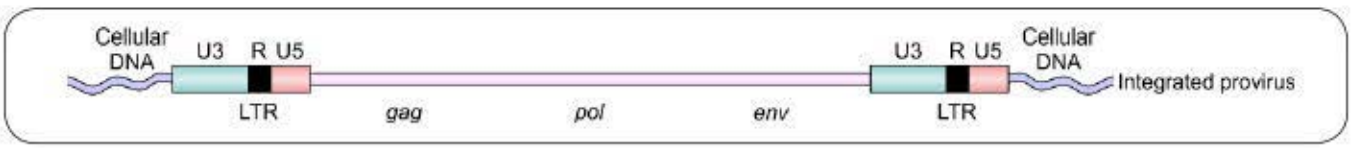

Fig. 51.1: Proviral DNA of retrovirus

- *Tax* gene also interferes with **DNA-repair pathways** (base excision repair and nucleotide excision repair) which leads to sustained DNA mutation.

Hepatitis C

Hepatitis C is the only oncogenic virus that does not get integrated with host chromosome but its RNA remains in the host cell. It is also strongly linked to the pathogenesis of liver cancer. The oncogenic mechanisms of HCV are less well defined than are those of HBV.

- Similar to HBV, chronic liver cell injury and compensatory regeneration seems to be the main mechanism.
- In addition, components of the HCV genome, such as the HCV core protein, may activate a number of growth-promoting signal transduction pathways.

ONCOGENIC DNA VIRUSES

Epstein Barr Virus

Epstein Barr virus (EBV) is associated with several malignancies:

- Burkitt's lymphoma (tumor of jaw, mostly seen in African children)
- Nasopharyngeal carcinoma
- Hodgkin's lymphoma (mixed-cellularity type)
- Non Hodgkin lymphoma (NHL)

Mechanism of Oncogenesis

Epstein Barr virus infects B lymphocytes and possibly pharyngeal epithelial cells by attaching to the complement receptor (CR2) or CD21.

- EBV does not actively replicate inside the B cells thus does not cause lysis of B cells, but such latently infected B cells with EBV become immortalized and acquire the ability to grow indefinitely in cell lines.
- Persistent EBV infection can induce malignant transformation of infected B cells and epithelial cells by expressing latent EBV antigens such as latent membrane protein (LMP) and EBNA (EBV nuclear antigen).
- Latent membrane protein-1 **(LMP-1)** is the most important viral oncogene.
  - It is coated on the surface of the infected cells and behaves as active CD40 receptor, a key recipient of helper T-cell signals that stimulate B-cell growth.
  - LMP-1 also activates the NF- κβ and JAK/STAT signalling pathways and promotes B-cell survival and proliferation.
  - LMP-1 prevents apoptosis by activating anti-apoptotic factor BCL2.
  - It induces the expression of pro-angiogenic factors such as vascular endothelial growth factor (VEGF) which may contribute to the oncogenesis of naso-pharyngeal carcinoma.
- **Viral EBNA-2** activates host cell **cyclin-D**, and the proto-oncogene *src*, thus promotes cell proliferation.
- **VIL-10 (viral interleukin 10):** It is a viral cytokine, which modulates the transformation of B cells.

Role of Host Immune Response and c-MYC

- Effective host immune response is crucial for preventing cell transformation. Oncogenicity is kept under control by anti LMP-1 antibodies.
- Thus, oncogenicity is markedly enhanced in immunosuppressed individuals who are not able to produce anti LMP-1 antibodies.
- More so, B cells in immunocompetent individuals can still undergo malignant transformation in presence of another pre-existing mutation (8;14) that in turn activates the growth promoting MYC oncogene.

Human Papillomavirus

More than 100 types of human papillomaviruses have been recognized. However, certain types (e.g., 16, 18, 30, 31, 33 and 45) have high oncogenic potential. They are associated with important malignancies such as:

- Squamous cell carcinomas of cervix
- Carcinoma of other genital mucosa (penis, vulva, vagina).
- Oropharyngeal carcinoma
- Laryngeal carcinoma
- Carcinoma of esophagus

Mechanism of Oncogenesis (Fig. 51.2)

Human papillomavirus genome consists of an early (E) region, a late (L) region. The early region consists of seven genes (E1-E7), which code for early non-structural proteins. Products of early genes E6 and E7 have oncogenic potential.

- E6 enhances p53 degradation, thus inhibiting the activation of apoptosis promoting gene *bax*. It leads to inhibition of apoptosis and also inhibits the p 53 induced activation of tumor suppressor gene p 21.
- E7 inhibits the tumor suppressor gene RB (retinoblastoma gene) either by:

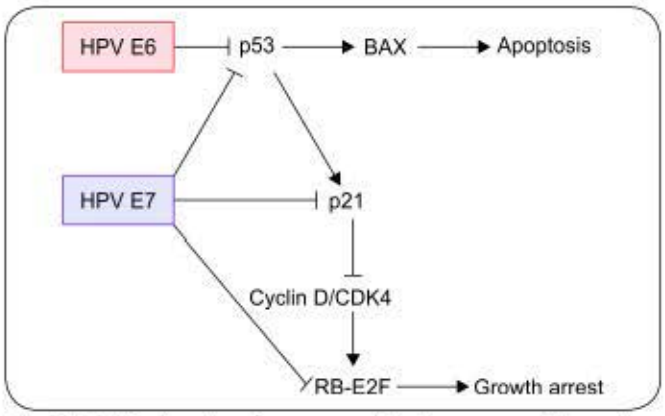

Fig. 51.2: Mechanism of oncogenesis by human papillomavirus

- Inhibiting p53
- Inhibiting p21
- Directly Inhibiting RB gene

However, HPV infection alone is not sufficient for carcinogenesis. Co-transfection with *v-fos* DNA results in full malignant transformation. There are several other factors that also have been implicated in the pathogenesis of HPV induced malignancies such as:

- Presence of other genetic co-factors like mutated *RAS* gene
- Cigarette smoking
- Coexisting microbial infections
- Dietary deficiencies
- Hormonal changes

Hepatitis B Virus

Hepatitis B virus (HBV), in adjunction with hepatitis C is responsible for 70–85% of hepatocellular carcinomas worldwide.

Mechanism of Oncogenesis

Although not fully elucidated, there are several mechanisms proposed for the oncogenesis of HBV. The HBV genome does not contain any oncogenes, however; it gets integrated with the host genome randomly in the target cells.

- **Immunologically mediated chronic inflammation** appears to be the most dominant mechanism in the pathogenesis of viral-induced hepatocellular carcinoma.
  - In chronic viral infection, hepatocellular injury occurs which is compensated by proliferation of hepatocytes. During the regenerative process, a plethora of growth factors, cytokines, chemokines, and other bioactive substances are produced by the activated immune cells which promote cell survival, tissue remodelling and angiogenesis.
  - The activated immune cells also produce reactive oxygen species, that are genotoxic and mutagenic.
  - One key molecular step seems to be activation of the NF-κβ pathway in hepatocytes which in turn blocks apoptosis, allowing the dividing hepatocytes to incur genotoxic stress and to accumulate mutations.
- **Hepatitis B X gene (HBx),** a regulatory gene in HBV genome, can activate the transcription of cellular and viral genes.
- **Deletion of tumor suppressor genes**: Integration of viral DNA with the host genome can cause secondary rearrangements of chromosomes which may lead to deletion of tumor suppressor genes.

Kaposi's Sarcoma

Kaposi's sarcoma is caused by human herpesvirus 8 (HHV8). It usually infects the endothelial cells and/or hematopoietic progenitor cells.

- The transformation of malignant cells is directly related to the expression of early lytic genes of HHV-8 such as viral G protein-coupled receptor K1,**viral interleukin-6 (vIL-6)** and K15.
- These genes induce the host cells to secrete the angiogenic, inflammatory and proliferative factors such as, vascular endothelial growth factor (VEGF), platelet-derived growth factor-β, angiopoietin 2, IL-6 and IL-8 that amount to continuous growth and transformation of cells.

EXPECTED QUESTIONS

I. Write short notes on:

1. List the human oncogenic viruses
2. Mechanism of oncogenesis of HTLV-I
3. Mechanism of oncogenesis of HPV
4. Mechanism of oncogenesis of EBV

II. Multiple Choice Questions (MCQs):

1. Which of the following is not an oncogenic virus?
   a. Hepatitis B virus
   b. Hepatitis C virus
   c. HIV
   d. Varicella-zoster virus

2. Epstein Barr virus is associated with the following malignancies except:
   a. Nasopharyngeal carcinoma
   b. Burkitt's lymphoma
   c. Carcinoma of cervix
   d. Non Hodgkin lymphoma

3. All of the following are oncogenic RNA viruses except:
   a. HTLV-I
   b. HIV
   c. Hepatitis B virus
   d. Hepatitis C virus

Answers

1. d **2.** c **3.** c

GENERAL MYCOLOGY

Medical mycology is the branch of medical science that deals with the study of medically important fungi. The name 'fungus' is derived from Greek '*mykes*' meaning mushroom (a type of edible fungus). Fungi differ from bacteria and other eukaryotes in many ways.

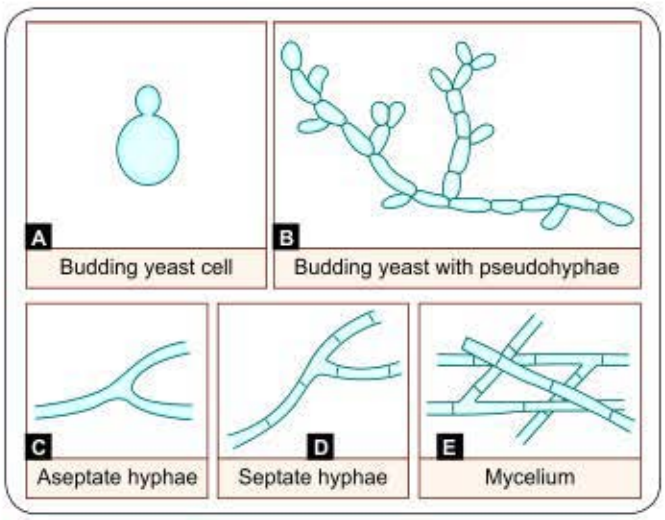
- Fungi are eukaryotic and they possess all the eukaryotic cell organelles such as mitochondria.
- They possess a rigid cell wall, composed of chitin, β-glucans and other polysaccharides.
- Fungal cell membrane contains ergosterol instead of cholesterol.
- Fungi may be unicellular or multicellular.
- They lack chlorophyll and divide by asexual and/or sexual means by producing spores.

CLASSIFICATION OF FUNGI

Morphological Classification

Based on the morphological appearance, there are four main groups of fungi given as follows: (Fig. 52.1):

1. **Yeast:** They grow as round to oval cells that reproduce by an asexual process called **budding** in which cells form protuberances which enlarge and eventually separate from the parent cells. Examples include:
   - *Cryptococcus neoformans* (pathogenic)
   - *Saccharomyces cerevisiae* (non-pathogenic)
2. **Yeast-like:** In some yeasts (e.g. *Candida*), the bud remains attached to the mother cell, elongates and undergoes repeated budding to form chains of elongated cells known as **pseudohyphae**. They can be differentiated from true hyphae as they have constriction at the septa and bear septa even at branching points.
3. **Molds:** They grow as long branching filaments of 2–10 µm wide called **hyphae**.
   - Hyphae are either septate (i.e. form transverse walls) or nonseptate (there are no transverse walls and they are multinucleated, i.e. coenocytic).
   - Hyphae grow continuously and form a branching tangled mass of growth called **mycelium**.



Figs 52.1A to E: Morphological forms of fungi

- In the culture medium, the mycelia may be categorized into two types of growth:
  1. **Aerial mycelium:** It is the part of the mycelium which projects above the surface of culture medium.
  2. **Vegetative mycelium:** It is the part of the mycelium that grows on the surface of the culture medium.
- Molds reproduce by formation of different types of sexual and asexual spores.
- Examples of true molds include—Dermatophytes, *Aspergillus*, *Penicillium*, *Rhizopus* and *Mucor*, etc.

4. **Dimorphic fungi:** They exist as molds (hyphal form) in the environment at ambient temperature (25°C) and as yeasts in human tissues at body temperature (37°C). Several medically important fungi are thermally dimorphic such as:
   - *Histoplasma capsulatum*
   - *Blastomyces dermatitidis*
   - *Coccidioides immitis*
   - *Paracoccidioides brasiliensis*
   - *Penicillium marneffei*
   - *Sporothrix schenckii*

Taxonomical Classification

Based on the production of sexual spores, the Kingdom Fungi has been divided into four medically important phyla. They are as follows.

1. Phylum zygomycota: They are lower fungi, produce sexual spores known as **zygospores** and possess aseptate hyphae, e.g. *Rhizopus* and *Mucor*.
2. Phylum ascomycota: They produce sexual spores known as **ascospores** and possess septate hyphae, e.g. *Aspergillus*.
3. Phylum basidiomycota: They produce sexual spores known as **basidiospore** e.g. *Cryptococcus*.
4. Phylum deuteromycota **(Fungi imperfecti):** In majority of the medically important fungi, the sexual state is either absent or unidentified yet. Hence, they are traditionally grouped as fungi imperfecti.

Types of fungal spores produced given in Table 52.1.

TABLE 52.1: Types of fungal spores

Sexual Spore	Observed in
Zygospores	Zygomycetes
Ascospores	*Aspergillus*
Basidiospores	*Cryptococcus*
Asexual Spore	**Observed in**
Vegetative asexual spore	
Arthrospore	*Coccidioides and Trichosporon*
Blastospore	*Candida*
Chlamydospore	*Candida albicans*
Aerial asexual spore	
Conidiospore or conidia	*Aspergillus*
Sporangiospore	Zygomycetes
Microconidia	Dermatophytes
Macroconidia	Dermatophytes

CLASSIFICATION OF FUNGAL DISEASES

Although more than 25,000 species of fungi are known, but most of them are saprophytes in soil and decaying plant materials. Only few are medically important. Fungal infections (or mycoses) can be categorized into following clinical types (Table 52.2):

- **Superficial mycoses:** These are the fungal infections involving the skin, hair, nail and mucosa.
- **Subcutaneous mycoses:** These are the mycotic infections of the skin, subcutaneous tissue and sometimes bone, resulting from inoculation of saprophytic fungi of soil or decaying matter. They are mainly confined to the tropics and subtropics.
- **Systemic mycoses:** They involve multiple organs. Mostly they are caused by the saprophytic fungi, which spread by inhalation of spores leading to pulmonary infection. From lungs, they disseminate to cause various systemic manifestations.
- **Opportunistic mycoses:** They are caused by the fungi that are normally found as human commensals or

*Superficial and systemic manifestations are also seen in candidiasis, cryptococcosis, aspergillosis and zygomycosis

in environment; but can act as human pathogen in presence of opportunities such as low immunity.

- **Mycotoxicoses:** They refer to the manifestations produced due to direct ingestion of fungal toxins.

LABORATORY DIAGNOSIS OF FUNGAL DISEASES

The laboratory diagnosis of fungal diseases comprises of the following:

Specimen Collection

It depends on the site of infection such as skin scrapping, hair, nail, sputum, etc. For systemic mycoses, blood sample may also be collected. Cerebrospinal fluid (CSF) is collected for cryptococcal meningitis.

Microscopy

Fungal elements can be detected in the clinical specimens by direct microscopic examination of material from the lesion.

- **Potassium hydroxide (KOH) preparation**: Keratinized tissue specimens such as skin scrapings and plucked hair samples are treated with 10% KOH which digests the keratin material so that the fungal hyphae will be clearly seen under the microscope.
  - 10% is the usual concentration of KOH used.
  - 20–40% KOH is needed for the specimens such as nail and biopsy tissues that take longer time to dissolve.
  - Glycerol (10%) is added to prevent drying.
  - DMSO (dimethyl sulfoxide) is added which helps in tissue digestion.
  - Caution should be maintained while interpretation of hyphae, which may be confused with collagen fiber, cotton fiber or hair present in the clinical specimens.
- **Gram stain:** It is useful in identifying the yeasts (e.g. *Cryptococcus*) and yeast like fungi (e.g. *Candida*). They appear as gram-positive budding yeast cells.
- **India ink and nigrosin stains:** They are used as negative stains for demonstration of capsule of *Cryptococcus neoformans*.
- **Calcofluor white stain:** It is more sensitive than other stains; binds to cellulose and chitin of fungal cell wall and fluoresce under UV light.
- **Histopathological stains:** They are useful for demonstrating fungal elements from biopsy tissues. This is useful for detecting fungi causing deep mycoses.
  - Periodic acid schiff (PAS) stain: It is the recommended stain for detecting fungi. PAS positive fungi appear magenta/deep pink, whereas the nuclei stain blue.
  - Gomori methenamine silver (GMS) stain: It is used as an alternative to PAS for detecting fungi. It stains both live and dead fungi, as compared to PAS which stains only the live fungi. GMS stains the polysaccharide component of the cell wall. Fungi appear black whereas the background tissue takes pale green color.
  - Mucicarmine stain: It is used for staining the carminophilic cell wall of *Cryptococcus* and *Rhinosporidium*.
  - Masson fontana stain: It is used for pigmented (or pheoid) fungi.
  - Hematoxylin and Eosin (H and E) stain.
- **Lactophenol cotton blue (LPCB):** It is used to study the microscopic appearance of the fungal isolates grown in culture. It contains:
  - Phenol acts as disinfectant.
  - Lactic acid preserves the morphology of fungi.
  - Glycerol prevents drying.
  - Cotton blue stains the fungal elements blue.

Culture

Fungal culture is frequently performed for isolation and correct identification of the fungi.

Culture Media

- **Sabouraud's dextrose agar (SDA):** It is the most commonly used media in diagnostic mycology. It contains peptone (1%), dextrose (4%) and has a pH of 5.6. This may not support some pathogenic fungi.

- **Neutral SDA** (Emmons' modification): It differs from original SDA in having neopeptone (1%) and dextrose (2%) and pH of 7.2.
- **Corn meal agar and rice starch agar:** They are the nutritionally deficient media used for stimulation of chlamydospore production.
- **Brain heart infusion (BHI) agar and blood agar:** They are the enriched media, used for growing fastidious fungi like *Cryptococcus* and *Histoplasma*.
- **Niger seed agar** and **bird seed agar:** They are used for the selective growth of *Cryptococcus*.
- **CHROMagar *Candida* medium:** It is used as selective as well as differential media for speciation of *Candida*.

Culture Condition

- **Temperature:** Most of the fungi grow well at 25–30°C except the dimorphic fungi that grow at both 25°C and 37°C.
- **BOD incubators** (biological oxygen demand): It is a special incubator used in diagnostic mycology, which is capable of maintaining low temperature.
- **Incubation time:** Culture plates should be incubated for 2–3 weeks.
- **Antibiotics** such as cycloheximide (actidione), chloramphenicol and gentamicin can be added to the culture media to inhibit bacterial growth.

Culture Identification

The correct identification of the fungus is based on the macroscopic and microscopic appearances of the colonies grown on culture.

Macroscopic Appearance of the Colony

- **Rate of growth:**
  - Rapid growth (<5 days): It is seen in saprophytes, yeasts and agents of opportunistic mycoses.
  - Slow growth (1–4 weeks): It is seen in agents of subcutaneous and systemic mycoses.
- **Pigmentation:** It can be seen on obverse and reverse of the culture media.
- **Texture:** It refers to how the colony would have felt if allowed to touch. It may be of various types such as—glabrous (waxy/leathery), velvety, yeast like or cottony or granular/powdery.
- **Colony topography**: Colony surface may be rugose (radial grooves), folded or verrucose or cerebriform (brain-like).

Microscopic Appearance of Fungi

- **Teased mount:** A bit of fungal colony is teased out from the culture tube and the LPCB mount is made on a slide and viewed under microscope. If proper teasing is not done, then the intact morphology may not be identified properly. Identification is based on the following:
  - Nature of hyphae (such as septate or aseptate, hyaline or phaeoid, narrow or wide) and
  - Type of sporulation (conidia or sporangia).
- **Slide culture:** Though this is a tedious procedure, it gives the most accurate *in situ* microscopic appearance of the fungal colony. A sterile slide is placed on a bent glass rod in a sterile petri dish. Two square agar blocks measuring around 1 cm^2 (smaller than the coverslip) are placed on the slide. Bits of fungal colony are inoculated onto the margins of the agar block. Then the coverslip is placed on the agar block and the petri dish is incubated at 25°C. LPCB mounts are made both from the coverslip and the underneath slide (Fig. 52.2).
- **Cellophane tape mount:** The impressions are taken by placing the cellophane tape on the colonies present on the surface of SDA plate, then LPCB mount is made from the cellophane tape. This is easy to perform than slide culture and *in-situ* fungal morphology is also maintained.

Other Methods of Identification

- For *Candida*: Germ tube test, Dalmau plate culture, sugar fermentation and sugar assimilation tests are done.

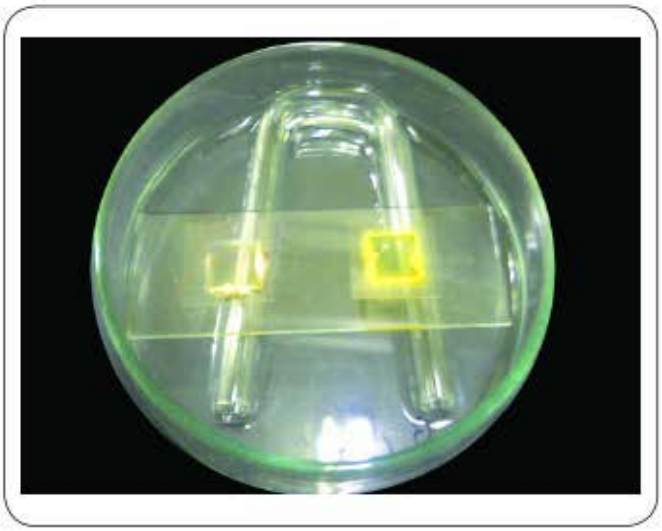

Fig. 52.2: Slide culture technique

TABLE 52.3: Antifungal agents, their mechanisms of action and uses

Class	Drug	Mechanisms	Use
Antifungal Antibiotics			
Polyenes	Amphotericin B (AMB)	Bind to ergosterol and disrupts fungal cell membranes	Systemic mycoses
	Nystatin, Hamycin		Topical use (skin infections)
Echinocandins	Caspofungin, micafungin	Inhibits β-glucan synthesis in fungal cell wall	Systemic mycoses
Benzofurans	Griseofulvin	Disrupts mitotic spindle by binding to fungal cell tubulin	Dermatophytoses
Synthetic Antifungal			
Azoles	Imidazoles ▪ Clotrimazole ▪ Miconazole ▪ Oxicozazole ▪ Ketoconazole	Inhibits ergosterol synthesis of fungi	Topical use (except, Ketoconazole can be used for both topical and systemic use)
	Triazoles ▪ Fluconazole ▪ Itraconazole ▪ Voriconazole ▪ Posaconazole	Inhibits ergosterol synthesis of fungi	Systemic mycoses
Antimetabolite	Flucytosine (5-FC)	Inhibits DNA synthesis in fungi; 5-FC is converted to fluorouracil, which inhibits thymidylate synthetase	Systemic mycoses Used in association with AMB
Allylamines	Terbinafine	Inhibits ergosterol synthesis of fungi	Topical use
Other topical agents	Tolnaftate, Benzoic acid, Whitfield's ointment, Undecylenic acid, Ciclopirox olamine		

- For dermatophytes: Hair perforation test, dermatophyte test medium and dermatophyte identification medium are used.
- Urease test can be done for the fungi that produce urease enzyme, e.g. *Cryptococcus*.

Immunological Methods

These tests are available to detect the antibody or antigen from serum and/or other body fluids.

- **Antibody detection** can be done by ELISA, immunodiffusion test, agglutination test, and complement fixation test (CFT).
- **Antigen detection:** Example includes latex agglutination test for detecting cryptococcal antigen from CSF.
- **Immunohistochemistry:** It refers to detecting antigens (e.g. proteins) on the cells of a tissue section by using fluorescent tagged antibodies that bind specifically to the antigens. It is useful in deep mycoses.

Tests for Metabolites

An alternate approach for the diagnosis of fungal infections is detection of specific fungal metabolites in body fluids by gas liquid chromatography.

Tests to Demonstrate Delayed Hypersensitivity

Skin tests are available for demonstrating delayed type of hypersensitivity for pathogens like *Histoplasma, Blastomyces, Coccidioides, Paracoccidioides, Dermatophyte, Sporothrix* and *Candida*.

Molecular Methods

Polymerase chain reaction (PCR) and its modifications such as multiplex PCR, nested PCR and the most advanced real time PCR and DNA sequencing methods have been developed for accurate identification of fungi from culture as well as from the specimens.

Antifungal agents, their mechanisms of action and their use have been described in Table 52.3.

SUPERFICIAL MYCOSES

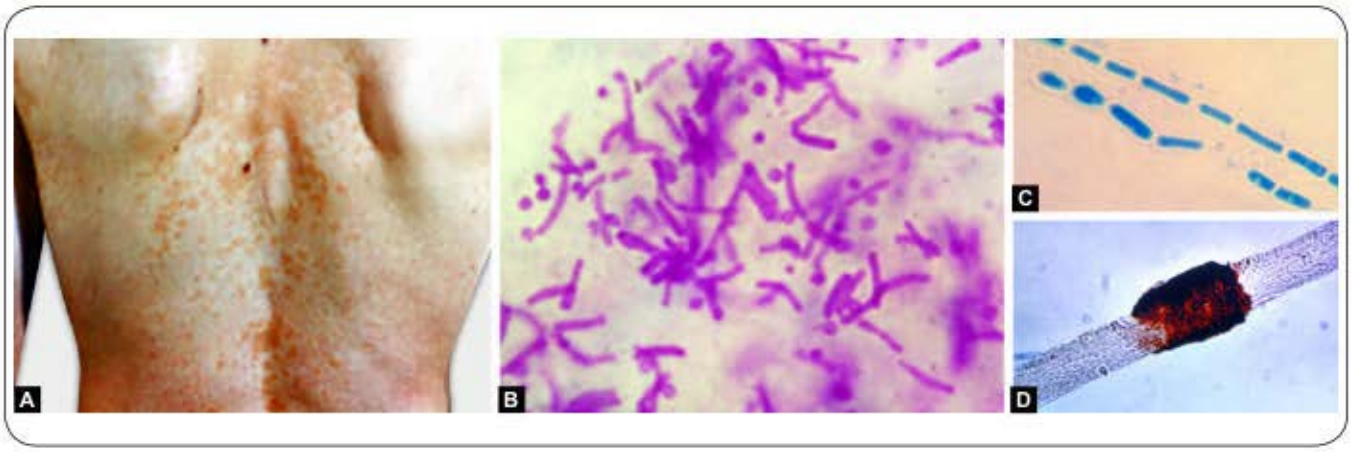
TINEA VERSICOLOR

Tinea versicolor (or pityriasis versicolor) is a chronic recurrent condition involving the superficial layer (stratum corneum) of skin, caused by a lipophilic fungus *Malassezia furfur*.

Clinical Manifestation

It is characterized by flat-round scaly patches of hypo to hyperpigmentation of skin (Fig. 52.3A).

- Lesions are non-inflammatory and non-pruritic (or rarely pruritic).
- Lesions can be mistaken for vitiligo, but the latter is not scaly.
- Areas rich in sebaceous glands are commonly involved such as neck, chest, or upper arms.
- Disease is more common in moist humid areas.



Figs 52.3A to D: A. Tinea versicolor (hypopigmented patches); **B.** *Malassezia furfur* (yeast cells and hyphae with spaghetti and meatballs appearance); **C** and **D.** Piedra; **C.** Arthrospores of *Trichosporon beigelii* (white piedra); **D.** Black nodule on hair shaft (black piedra)

Source: Public Health Image Library/ Dr. Lucille K.G. A. ID# 12534; B. ID# 2916; C. ID# 3936 and D. ID#:3937/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Other manifestations caused by *Malassezia furfur* include:

- Seborrheic dermatitis: It manifests as erythematous pruritic scaly lesions called **dandruff in adults** and cradle cap in babies. It can be severe in patients with advanced AIDS.
- Atopic dermatitis.
- Folliculitis (hair follicle infection).
- Disseminated infection occur rarely.

Laboratory Diagnosis

Diagnosis of tinea versicolor is largely made clinically. The laboratory diagnostic methods are as follows.

- **Direct microscopy:** Skin scrapings are examined microscopically after treating with 10% KOH. Mixture of budding yeasts and short septate hyphae are seen, described as **spaghetti and meatballs** appearance (Fig. 52.3B).
- **Culture:** *Malassezia furfur* being lipophilic, SDA with olive oil overlay is the ideal media for culture. Typical '**fried egg**' colonies appear after incubating for 5–7 days at 32–35°C.
- **Urease test:** It gives a positive urease test.
- **Wood's lamp examination:** Under Wood's lamp, the scaly lesions show golden yellow fluorescence.

TREATMENT	Tinea versicolor
Topical lotions like selenium sulfide shampoo, ketoconazole shampoo or cream, terbinafine cream should be used for 2 weeks.	

TINEA NIGRA

It is characterized by painless, black, non-scaly patches present on palm and sole; more commonly in females. It is caused by *Hortaea werneckii*. It is a black colored yeast like fungus.

PIEDRA

Piedra is characterized by nodule formation on hair shaft, which may be either black or white in color.

White Piedra

Here, white nodules are formed on the hair shaft, which are less firmly attached.

- **Agent:** *Trichosporon beigelii*
- **Identifying feature**: *T. beigelii* is an urease positive, yeast like fungus; produces creamy white colonies, containing hyaline septate hyphae intervening with rectangular **arthrospores** (Fig. 52.3C).

Black Piedra

It is characterized by formation of black nodules, which are firmly attached to the hair shaft (Fig. 52.3D).

- **Agent:** *Piedraia hortae*
- **Identifying feature:** It is a phaeoid fungus; produces reddish brown colonies; containing dark brown thick septate hyphae with ascus containing ascospores.

DERMATOPHYTOSES

Dermatophytoses (or tinea or ringworm) is the most common superficial mycoses affecting skin, hair and nail;

TABLE 52.4: Classification of dermatophytes based on their usual habitat

Habitat	*Trichophyton*	*Microsporum*	*Epidermophyton*
Anthropophilic	*T. rubrum* *T. mentagrophytes* *T. schoenleinii* *T. tonsurans* *T. violaceum*	*M. audouinii*	*E. floccosum*
Zoophilic	*T. equinum* *T. verrucosum*	*M. canis* *M. equinum*	
Geophilic	*T. ajelloi*	*M. gypseum*	*E. stockdaleae*

caused by a group of related fungi (called **dermatophytes**) that are capable of infecting keratinized tissues. These include:

- *Trichophyton* species: Infect skin, hair and nail.
- *Microsporum* species: Infect skin and hair.
- *Epidermophyton* species: Infect skin and nail.

Depending on the usual habitat (humans, animals, or soil), dermatophytes are classified as follows (Table 52.4):

- Anthropophilic: These are the fungal species exclusively infecting humans.
- Zoophilic: They infect animals as well as birds.
- Geophilic: These fungal species are frequently isolated from soil.

Pathogenesis

Dermatophyte infection is acquired by direct contact with soil, animals or humans infected with fungal spores. Then the spores are carried to different areas due to scratching of the inoculated site. Predisposing factors include moist humid skin and tight-ill fitting underclothing.

- **Skin:** Dermatophytes grow in a centrifugal pattern in the stratum corneum; leads to formation of characteristic well-demarcated **annular** or **ring** shaped pruritic scaly skin lesions with central clearing and raised edges. Scaling, erythema, and rarely blister formation may occur.
- **Nails:** They invade the nails through the lateral or superficial nail plates and then spread throughout the nails;
- **Hair shafts:** Dermatophytes can invade within the hair shaft or may be found surrounding it. Hairs become brittle and areas of alopecia may appear.
- Lesions are not produced by the tissue invasion by the fungi per se; but in response to the host's inflammatory reaction elicited by fungal antigens.
- Males are commonly infected than females as progesterone is inhibitory to dermatophyte growth.
- Severity depends on the infecting fungi, immune status of the host and the site of lesion.
- Anthropophilic dermatophytes are the most common dermatophytes affecting humans. They cause relatively mild and chronic lesions but respond poorly to treatment.
- In contrast, geophilic and zoophilic species, being less adapted to human hosts, produce more acute inflammatory response and severe infections; but they tend to resolve more quickly.

Clinical Types

Depending on the site of involvement, various clinical types of dermatophytic or tinea or ring worm infections are produced (Table 52.5). Incubation period is about 1–2 weeks.

TABLE 52.5: Clinical types of dermatophytoses

Clinical types		Area involved
Tinea capitis (infection of the scalp)		Scaly patches are produced on scalp, in which hair shafts are broken off right above the skin. It is of various types.
1	Kerion	It is a painful inflammatory reaction, producing boggy lesions on scalp. Agent: *Trichophyton verrucosum*
2	Favus	Cup like crust (scutula) is formed around the infected hair follicle with minimal hair shaft involvement (Fig. 52.4A). Agent: *Trichophyton schoenleinii*
3	Ectothrix	Arthrospores are formed on the surface of hair shaft Agent: *M. audouinii, M. canis,* and *T. mentagrophytes.*
4	Endothrix	Arthrospore are formed within the hair completely filling the hair shaft, thus, can result in alopecia. Agent: *T. tonsurans* and *T. violaceum*
Tinea corporis		Infection of the non-hairy skin of the body (trunk and limbs) (Fig. 52.4D)
Tinea pedis (athlete foot)		Infection of the web space between the toes, which then spreads to the sole in a "**moccasin**" pattern (Fig. 52.4C)
Tinea cruris (or jock itch)		Infection of the groin area
Tinea barbae		Infection of the beard and moustache area of face
Tinea faciei		Infection of the non-bearded area of face (Fig. 52.4B)
Tinea imbricata		Concentric lesions of the skin Agent: *T. concentricum*
Tinea unguium (nail plate infection)		Infection of nail beds Agent: *T. mentagrophytes* and *E. floccosum*
Tinea manuum		Infection of the palmar aspect of hands

Dermatophytid or Id Reaction

Occasionally, hypersensitivity to dermatophyte antigens may occur, which leads to appearance of secondary eruption in sensitized patients because of circulation of allergenic products. However, these lesions are distinct from the primary ringworm lesions as they occur distal to primary site and fungal culture often turns negative.

Laboratory Diagnosis

Woods Lamp Examination

Certain dermatophytes fluoresce when the infected lesions are viewed under Wood's lamp. It is usually positive for various *Microsporum* species and *Trichophyton schoenleinii*. Other dermatophytes do not fluoresce under Wood's lamp. Fluorescence is due to the presence of pteridine pigment in cell wall.

Specimen Collection

Skin scrapings, hair plucks (broken or scaly ones) and nail clippings are obtained from the active margin of the lesions and are kept in folded black paper. Hairs should be plucked, but not cut.

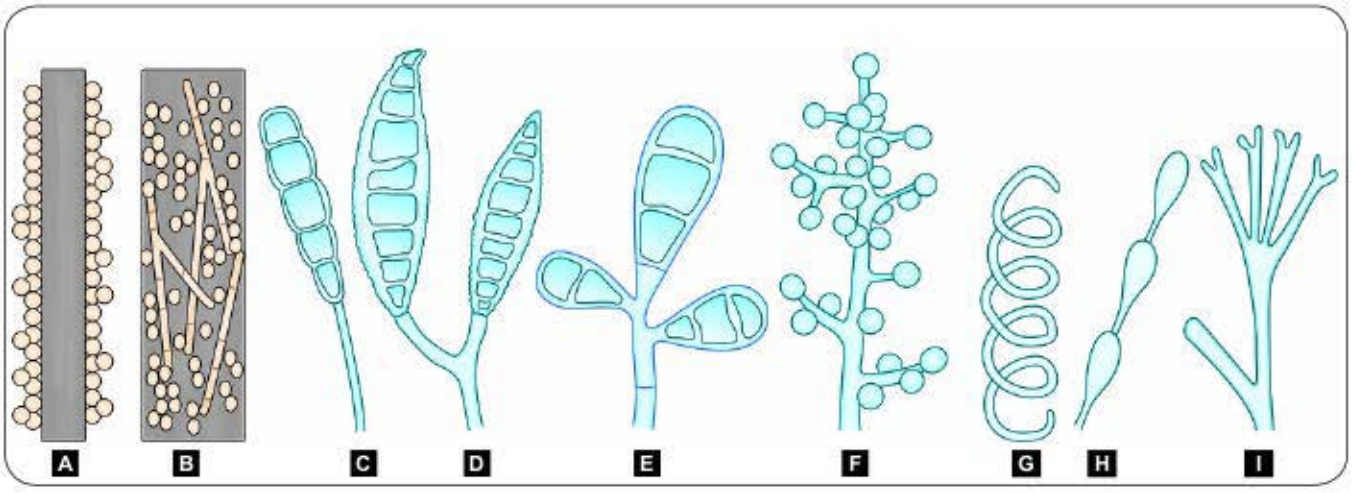
Direct Examination

The specimen is mounted in KOH (10% for skin scrapings or hair, 20–40% for nail clippings) or calcofluor white stain and is examined for the presence of thin septate hyaline hyphae with arthroconidia. When hair is involved, the arthroconidia may be found on the surface of the hair shaft (ectothrix) or within the shaft (endothrix) (Figs 52.5A and B).

Culture

Specimens should be inoculated onto SDA containing cycloheximide and incubated at 26–28°C for 4 weeks. Potato dextrose agar is used to stimulate the sporulation. Identification is made by:

- **Macroscopic appearance** of the colonies such as—rate of growth, texture, pigmentation, colony topography.



Figs 52.5A to I: **A.** Ectothrix; **B.** Endothrix infection of hair shaft by dermatophytes; **C** to **E.** Macroconidia of various dermatophyte species; **C.** *Trichophyton mentagrophytes;* **D.** *Microsporum canis;* **E.** *Epidermophyton floccosum;* **F.** Microconidia of *Trichophyton mentagrophyte;* **G** to **I.** Special types of hyphae seen in dermatophytes. **G.** Spiral hypha; **H.** Racquet hypha; **I.** Favic chandelier

TABLE 52.6: Distribution of conidia of dermatophytes

Dermatophytes*	Macroconidia	Microconidia
Trichophyton	Rare, thin walled, smooth, pencil shaped	Abundant
Microsporum	Numerous, thick walled, rough, spindle shaped	Rare
Epidermophyton	Numerous, smooth walled, club shaped	Absent

*Appearance of microconidia and macroconidia may vary depending on the dermatophyte species

- **Microscopic appearance:** The colonies are teased and LPCB mount is made to demonstrate the hyphae and spores (or conidia):
  - **Conidia:** Two types of spores or conidia are observed such as small unicellular **microconidia,** and large septate **macroconidia**; both are used for identification of species (Table 52.6 and Figs 52.5C to F).
  - **Special hyphae:** Dermatophytes possess thin septate hyaline hyphae; some species have specialized hyphae such as spiral hyphae, racquet hyphae and favic chandeliers (Fig. 52.5G to I).

Identification features (macroscopic and microscopic) of commonly encountered dermatophyte species is given in Table 52.7.

Other Methods of Diagnosis

Apart from culture, there are several other methods available for identification of dermatophytes such as:

- **Hair perforation test:** It is positive for *Trichophyton mentagrophytes* and *Microsporum canis*. The test is performed by inoculating a colony into a petri dish containing water, yeast extract, and hair. Fungi pierce the hair producing wedge shaped perforations.
- **Urease test:** *Trichophyton mentagrophytes* is urease positive.
- **Dermatophyte test medium** and **Dermatophyte identification medium:** They are used for presumptive identification. These tests are based on color change in the medium due to production of alkali metabolites.
- **Molecular methods:** PCR can be used to detect species specific genes (e.g. chitin synthase gene)
- **Skin test:** It is done for detecting hypersensitivity to dermatophyte antigen (trichophytin).

TREATMENT **Dermatophytoses**

- **Oral terbinafine or itraconazole** are the drugs of choice for treatment of dermatophytosis. Duration of treatment depends on the affected site (1–2 weeks for skin lesions, 6 weeks for hair infection, 3 months for onychomycosis). They can be given as pulse therapy.
- Alternate: Oral griseofulvin and ketoconazole may be given.
- Topical lotion such as whitfield ointment or tolnaftate can be applied.

TABLE 52.7: Identification features of commonly encountered dermatophyte species

Dermatophytes	Macroscopic appearance	Microscopic appearance
T. rubrum	Velvety, red pigment on reverse	Microconidia—tear drop shaped, plenty Macroconidia—few, long, pencil shaped
T. mentagrophytes (Figs 52.6A, 52.7A)	White to tan Powdery Pigment variable	Microconidia—numerous, round to pyriform Macroconidia—cigar shaped Spiral hyphae seen
T. schoenleinii	Smooth, waxy	Microconidia and macroconidia—rare or absent Chlamydospores seen Hyphae—hyphal swelling and favic chandelier seen
T. violaceum	Slow growing, waxy Violet pigment on reverse	Microconidia and macroconidia—rare or absent Distorted hyphae seen Chlamydospores seen
M. audouinii	Slow growing, velvety, brownish	Thick walled chlamydospores seen Macroconidia and microconidia—rare
M. gypseum	Buff colored, powdery	Macroconidia—abundant, thick walled, spiny, spindle shaped, 4-6 septa, rounded ends Microconidia—rare
M. canis (Figs 52.6B, 52.7B)	Cottony, orange pigment on reverse	Macroconidia—abundant, thick walled, spiny, spindle shaped, up to 15 septa, pointed ends Microconidia—rare
E. floccosum (Figs 52.6C, 52.7C)	Powdery, folded, yellowish green	Macroconidia club or clavate shaped in clusters, 4–6 septa Microconidia—absent

SUBCUTANEOUS MYCOSES

The agents of subcutaneous mycoses usually inhabit the soil. They enter the skin by traumatic inoculation with contaminated material and tend to produce the granulomatous lesions in the subcutaneous tissue.

MYCETOMA

Mycetoma is a chronic, slowly progressive granulomatous infection of the skin and subcutaneous tissues.

- Clinically, it is manifested as a triad of swelling, discharging sinuses and presence of granules in the discharge.
- Mycetoma is also known as **Maduramycosis** or **Madura foot,** as it was first described in Madurai, South India, by John Gill (1842).

Types of Mycetoma and Causative Agents

Mycetoma can be of two types. It can be caused by either fungal agents (eumycetoma) or bacterial agents (actinomycetoma). They differ from each other by various properties like color of granules/grains and in clnical manifestations, etc (Tables 52.8 and 52.9).

There is a third category called **botryomycosis** which refers to a mycetoma like condition caused by some bacteria such as *Staphylococcus aureus*.

TABLE 52.8: Agents of mycetoma and types of grains they produce

Eumycetoma	Actinomycetoma
Black granules: ▪ *Madurella mycetomatis* ▪ *Madurella grisea* ▪ *Exophiala jeanselmei* ▪ *Curvularia* species **White granules:** ▪ *Pseudallescheria boydii* ▪ *Aspergillus nidulans* ▪ *Acremonium* species ▪ *Fusarium* species	**White to yellow granules:** ▪ *Nocardia* species ▪ *Streptomyces somaliensis* ▪ *Actinomadura madurae:* It is the most frequent cause, significantly out numbering the cases caused by *Nocardia* **Pink to red granules:** *Actinomadura pelletieri*

Pathogenesis

The causative agents enter the skin or subcutaneous tissue from the contaminated soil, usually by the accidental trauma such as thorn prick or splinter injury. Then the disease evolves slowly; initially micro abscesses are formed by the polymorphs, replaced later by chronic granulomatous tissue in skin and subcutaneous tissues.

Clinical Manifestations

Hallmark of mycetoma is presence of clinical triad consisting of (Fig. 52.8):

- Tumor like swelling, i.e. tumefaction
- Discharging sinuses
- Discharge oozing from sinuses containing granules

Eumycetoma and actinomycetoma vary clinically (Table 52.9). Feet are the most common site affected, although any site can be involved. There may be involvement of underlying fasciae and bones, producing osteolytic or osteosclerotic bony lesions. Lesions are usually painless.

Fig. 52.8: Mycetoma of foot

Source: Public Health Image Library/ ID#: 14816/Centers for Disease Control and prevention (CDC), Atlanta (*with permission*)

TABLE 52.9: Clinical manifestations of eumycetoma and actinomycetoma

Clinical manifestations	Eumycotoma	Actinomycotoma
Tumor	Single, well-defined margins	Multiple tumor masses with ill defined margins
Sinuses	Appear late, few in number	Appear early, numerous with raised inflamed opening
Discharge	Serous	Purulent
Grains	Black/white	White/ red
Bone	Osteosclerotic lesions	Osteolytic lesions
Grains contain	Fungal hyphae (> 2 um)	Filamentous bacteria (< 2 um)

Epidemiology

Mycetoma is endemic in Africa, India, the Central and South America, and has a non-uniform distribution.

- Overall, actinomycetoma is more common (60%) than eumycetoma (40%) globally, whereas eumycetoma is more common in Africa.
- However, within a country, the distribution may vary in different regions.
- A meta-analysis is done in 2013 showed that most of the cases are reported globally from Mexico, Sudan and India.
- In India, Rajasthan reports the maximum cases of mycetoma per year followed by Tamil Nadu and West-Bengal. Actinomycetoma predominates in India (65%), except in Rajasthan where eumycetoma is more common.

Laboratory Diagnosis

Specimen Collection

The lesions should be cleaned with antiseptics and the grains should be collected on sterile gauze by pressing the sinuses from periphery or by using a loop.

Direct Examination

Granules are thoroughly washed in sterile saline; crushed between the slides and examined.

- **Macroscopic appearance of granules** such as color, size, shape, texture may provide important clue to identify the etiological agent.
- **If eumycetoma is suspected:** Grains are subjected to KOH mount, which reveals hyphae of 2–6 µm width along with chlamydospores at margin.

- **If actinomycetoma is suspected:** Grains are subjected to Gram staining which reveals filamentous gram-positive bacilli (0.5–1µm wide). Modified acid fast stain is performed if *Nocardia* is suspected, as it is partially acid fast.
- **Histopathological staining of the granules:**
  - Eumycetoma: Reveals granulomatous reaction with palisade arrangement of hyphae in the cement substance (Fig. 52.9A).
  - Actinomycetoma: Shows granulomatous reaction with filamentous bacteria at the margin (Fig. 52.9B).

Culture

Granules obtained from deep biopsies are the best specimen for culture as it contains live organisms. Both fungal (e.g. SDA) and bacteriological media (such as Lowenstein Jensen media) should be included in the panel.

- Identification of the eumycetoma agents is usually carried out by observation of the growth rate, colony morphology, production of conidia and their sugar assimilation patterns.
- Agents of actinomycetoma can be identified by their growth rate, colony morphology, urease test, acid fastness and decomposition of media containing casein, tyrosine, xanthine.

TREATMENT **Mycetoma**

Treatment of mycetoma consists of surgical removal of the lesion followed by use of:

- Antifungal agents for eumycetoma (itraconazole or amphotericin B for 8–24 months) or
- Antibiotics for actinomycetoma such as Welsh regimen (amikacin plus cotrimoxazole).

SPOROTRICHOSIS

Sporotrichosis or Rose Gardner's disease is presented as subcutaneous nodulo-ulcerative lesions; caused by a thermally dimorphic fungus, *Sporothrix schenckii*.

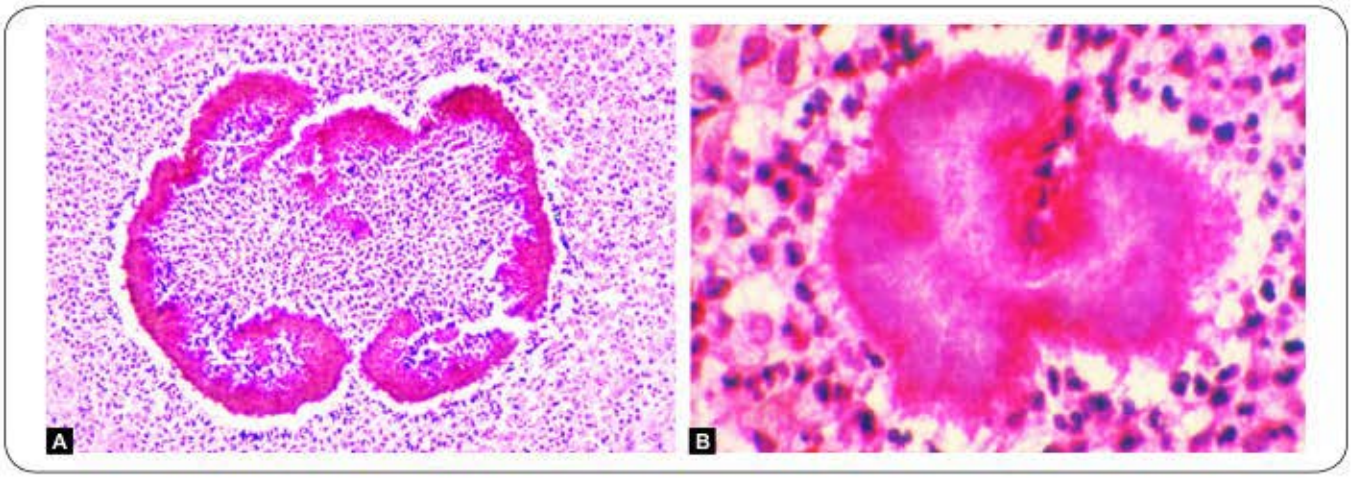
Pathogenesis

Spores of *S. schenckii* are introduced into skin following minor trauma caused by thorn prick or splinter injury. Enzymes secreted by the fungus, such as serine proteinase and aspartic proteinase help in local invasion. *S. schenckii* has a typical tendency to spread along the lymphatics.

Clinical Manifestations

Sporotrichosis is a chronic subcutaneous pyogranulomatous disease. Incubation period is about 3 weeks. Various clinical types have been observed.

- **Lympho-cutaneous type:** It is the most common type (80%) and is characterized by:
  - Nodulo-ulcerative lesions (painless) occur along the lymphatics.
  - Lymph nodes become enlarged, suppurative, indurated and have cord like feeling on palpation.
- **Other clinical types** are rare such as:
  - Osteoarticular type: It is seen among alcoholics.
  - Pulmonary type: It occurs following spore inhalation, seen in people with underlying chronic obstructive pulmonary disease (COPD).
  - Disseminated sporotrichosis: It occurs in immunocompromised patients (such as AIDS).
  - Fixed cutaneous type: Single nodule is found, that is less progressive and does not spread by lymphatics. It is more common in endemic areas such as Mexico where people show strong immunity against the fungi.



Figs 52.9A and B: A. Eumycetoma (black grain and cement like substance); **B.** Actinomycetoma caused by *Nocardia brasiliensis* (hematoxylin-eosin staining)

Source: Public Health Image Library/ A. ID#: 4331, B. ID#: 15055/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Epidemiology

Sporotrichosis is prevalent in tropical countries with high humidity.

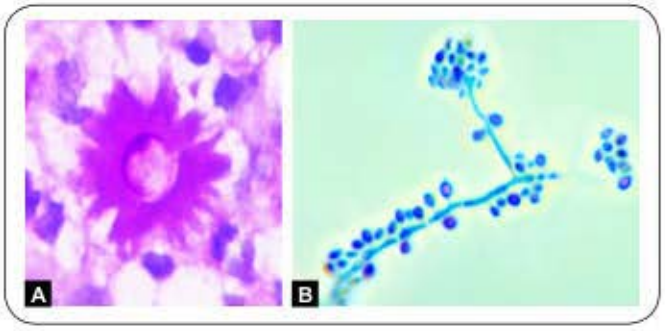
- **World:** It has been reported frequently from Central South America, South Africa and India.
- **In India**, sporotrichosis is prevalent in sub Himalayan hilly areas of northeast states ranging from Himachal Pradesh to Assam. Other endemic foci are northern Karnataka and southern Maharashtra.
- **Source:** *S. schenckii* has been isolated from decaying vegetations (such as wood, bark, leaves), and soil.
- **Risk factors** include people walking bare foot, certain occupations such as farmers and gardeners.

Laboratory Diagnosis

- **Direct microscopy:** Specimens such as pus, aspirate from nodules, curettage or swabbing from ulcers are subjected to KOH mount or calcofluor staining which demonstrate elongated yeast cells of 3–5μm in diameter. But the sensitivity is very low.
- **Histopathological staining** (e.g. hematoxylin and eosin) of tissue sections reveals cigar shaped asteroid bodies.

> **Asteroid body** consists of a central basophilic yeast cell surrounded by radiating extensions of eosinophilic mass, composed of antigen-antibody complexes (Fig. 52.10A). Such eosinophilic halo is described as **Splendore-Hoeppli phenomenon**. It is commonly observed in endemic areas.

- **Culture:** It is the most definitive tool for diagnosis. Specimens are inoculated onto SDA and blood agar in duplicate and incubated at 25°C and 37°C simultaneously, because *S. schenckii* is a dimorphic fungus.
  - **At 25°C:** It produces mycelial form, consisting of slender delicate hyphae with conidia arranged in **flower-like pattern** (Fig. 52.10B).
  - **At 37°C:** It produces yeast form, characterized by moist creamy white colonies which turn brown black in 10–14 days.
- **Serology:** Latex agglutination test detects serum antibodies in patients with extracutaneous form of the disease, but is not always diagnostic.
- **Skin test:** It may demonstrate delayed type of hypersensitivity reaction against sporotrichin antigen.



Figs 52.10A and B: *Sporothrix schenckii*. **A.** Yeast form (asteroid body); **B.** Mold form showing thin septate hyphae with flower-like sporulation

Source: A. Dr Manoj Singh and Dr M Ramam, AIIMS, New Delhi, B. Public Health Image Library/ Dr.Libero Ajello B. ID#: 4208/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT — Sporotrichosis

Itraconazole is the drug of choice for all forms of sporotrichosis; except for disseminated form where amphotericin B is recommended. Treatment is given until 2–4 weeks after the lesions resolve.

CHROMOBLASTOMYCOSIS

Chromoblastomycosis refers to slow growing chronic subcutaneous lesions caused by group of dematiaceous or phaeoid fungi (i.e. darkly pigmented fungi) that produce a characteristic morphology called **sclerotic body**.

- **Agents** of chromoblastomycosis include:
  - *Fonsecaea pedrosoi* and *F. compacta*
  - *Phialophora verrucosa*
  - *Cladosporium carrionii*
  - *Rhinocladiella aquaspersa*
- **Lesions** are typically slow growing and polymorphic, such as verrucose (most common type), crusted, ulcerative and nodular or tumor like.
- Most commonly seen in tropical or subtropical climates, often in rural areas.
- **Sclerotic bodies:** Histopathological appearance of these fungi is characterized by formation of brown thick walled round cells (5–12 μm size) with multiple internal transverse septa. They are also called **Medlar bodies** or **muriform cells**.

TREATMENT — Chromoblastomycosis

It consists of surgical removal (cryosurgery or laser therapy) of the lesion followed by antifungals (itraconazole).

PHAEOHYPHOMYCOSIS

Phaeohyphomycosis refers to chronic subcutaneous lesions, caused by dematiaceous or phaeoid fungi other than that are described in chromoblastomycosis (i.e. they do not produce sclerotic bodies). They exist in mycelial form. Agents include:

- *Alternaria* species
- *Bipolaris* species

- *Curvularia* species
- *Exophiala jeanselmei*
- *Cladophialophora bantiana* (it is neurotropic, produces brain abscess, frontal lobe being the most common site affected).

RHINOSPORIDIOSIS

Rhinosporidiosis is a chronic granulomatous disease, characterized by **large friable polyps in the nose** (most common site), conjunctiva and occasionally in ears, larynx, bronchus and genitalia.

- **Agent:** It is caused by *Rhinosporidium seeberi*, a lower aquatic fungus. Its taxonomic status is controversial; some believe that it may be a hydrophilic protist.
- **Source:** Stagnant water is the main source of infection. Fungal spores are inhaled while taking bath in contaminated ponds and rivers.
- **Distribution:** Rhinosporidiosis is common in tropical countries, especially in Sri Lanka and India (Tamilnadu, Kerala, Orissa and Andhra Pradesh).
- **Diagnosis** is made by histopathology of the polyps that demonstrates **spherules** (large sporangia up to 350 µm size, that contain numerous endospores, each 6–9 µm in size) (Fig. 52.11). It is stained better with mucicarmine stain. *R. seeberi* has not been cultivated yet.

TREATMENT **Rhinosporidiosis**

Radical surgery with cauterization is the mainstay of treatment. Dapsone has been found to be affective. Recurrence is common.

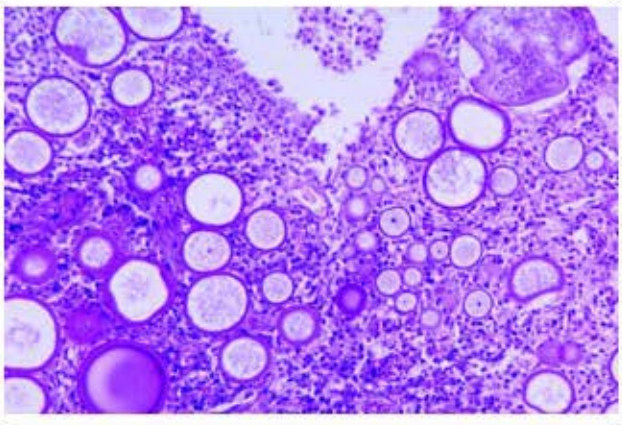


Fig. 52.11: *Rhinosporidium seeberi*—spherules containing sporangia filled with endospores (H and E stain)

Source: Public Health Image Library/Dr. Martin Hicklin/ID#: 3107/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

SYSTEMIC MYCOSES

HISTOPLASMOSIS

Histoplasmosis is a systemic granulomatous disease caused by a dimorphic fungus, *Histoplasma capsulatum*. The species name is a misnomer as it is not capsulated. It was first reported by Samuel Darling (1905), hence is also known as **Darling's disease**. It has three varieties:

1. *H. capsulatum* var. *capsulatum:* It causes classical histoplasmosis (most common type)
2. *H. capsulatum* var. *duboisii:* It causes African histoplasmosis
3. *H. capsulatum* var. *farciminosum:* It causes epizootic histoplasmosis.

The descritpion below is confined to *H. capsulatum* var. *capsulatum*. The other two varieties are described thereafter.

Epidemiology

Histoplasmosis occurs worldwide, but is endemic in USA, particularly in states bordering the Ohio River valley and the lower Mississippi River. In India, it is reported frequently from the region of West Bengal along the Ganga River. The fungus inhabits in the humid and acidic soil that contains large amount of bird or bat droppings.

Pathogenesis

H. capsulatum is transmitted by inhalation of spores (i.e. microconidia) which usually circulate in the air after the contaminated soil is disturbed.

- After the spores enter into the lungs, they are engulfed inside the alveolar macrophages and then transform into yeast forms.
- The yeasts survive within the phagolysosome of the macrophage by producing alkaline substances, such as bicarbonate and ammonia.
- Then, the intracellular yeasts travel to the lymph nodes and spread to the other parts of the body through bloodstream.
- Majority of the infected people show strong cell-mediated immune response (CMI) within 2 weeks. Granulomas are formed which later get healed with fibrosis and calcification. Unlike latent tuberculosis, histoplasmosis once healed, rarely reactivates.
- However, in patients with impaired CMI, the disseminated infection sets in.

Clinical Manifestations

Clinically, the classical histoplasmosis ranges from asymptomatic infection (in immunocompetent people) to life-threatening illness seen in people with low CMI. The various clinical types include:

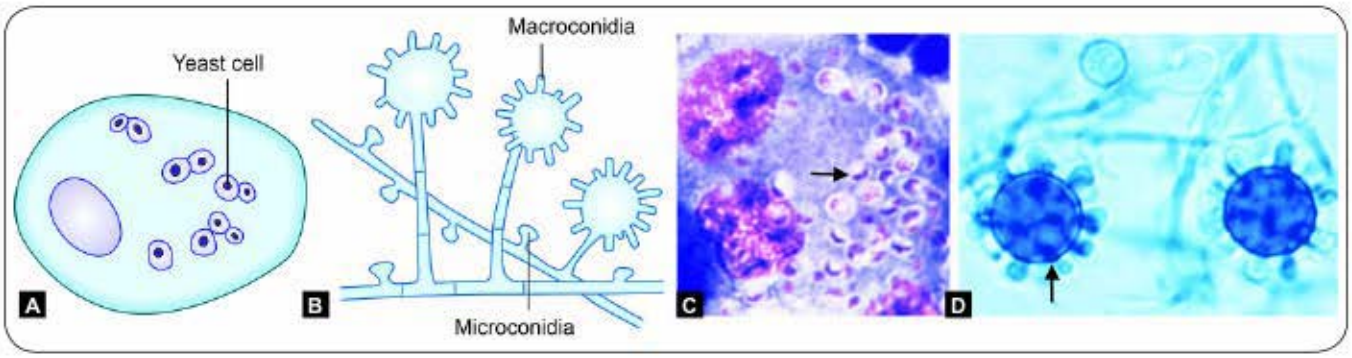
Fig. 52.12: Oral lesions of histoplasmosis (*arrow showing*)

Source: Public Health Image Library/Dr. Lucille K. Georg/ID#:15363/Centers for Disease Control and Prevention (CDC), Atlanta. (*with permission*)

- **Pulmonary histoplasmosis:** It is the most common form.
  - Acute form presents with mild flu like illness, pulmonary infiltrates in chest X-ray with hilar or mediastinal lymphadenopathy.
  - Chronic cavitary histoplasmosis may be seen in smokers with underlying structural lung disease.
- **Mucocutaneous histoplasmosis:** Skin and oral mucosal lesions may develop secondary to pulmonary infection. Oral lesions are particularly seen in Indian patients (Fig. 52.12).
- **Disseminated histoplasmosis:** It develops if CMI is very low (e.g. untreated HIV infected people or following organ transplantation). The common sites affected are bone marrow, spleen, liver, eyes and adrenal glands.

Laboratory Diagnosis

- **Specimens:** Useful specimens include sputum, aspirate from bone marrow and lymph node, blood and biopsies from skin and mucosa.
- **Direct microscopy:** Histopathological staining (such as PAS, Giemsa or GMS stain) of the specimens reveals tiny oval yeast cells (2–4 µm size) with narrow based budding within the macrophages with an underlying granulomatous response (Figs 52.13A and C).
- **Culture:** It is the gold standard method of diagnosis. Specimens should be inoculated onto media such as SDA, blood agar and BHI agar in duplicate and incubated simultaneously at 25°C and 37°C. *Histoplasma* is a dimorphic fungus, hence:
  - **At 25°C:** It forms mycelial phase; produces white to buff brown colonies that consist of two types of conidia or spores:
    1. Tuberculate macroconidia, with typical thick walls and finger-like projections which is a characteristic feature of this fungus (Figs 52.13B and D).
    2. Microconidia are smaller, thin, and smooth-walled.
  - **At 37°C:** It gets converted into yeast form (creamy white colonies), which is best developed in special media like Kelley's media.
- **Serology:** Antibodies in serum can be detected by CFT and immunodiffusion test.
  - Antibodies appear after 1 month of infection; hence are more useful in chronic stage; but are often negative in early course and in disseminated stage.
  - False positive result may occur due to past infection or cross infection with *Blastomyces*.
- **Skin test:** It may be done to demonstrate delayed type hypersensitivity response to histoplasmin antigen, which indicates prior exposure.



Figs 52.13A to D: **A** and **B.** *Histoplasma capsulatum* (schematic diagram). **A.** Yeast form; **B.** Mycelial form; **C** and **D.** *Histoplasma capsulatum*; **C.** 2–4 µm yeast cells with narrow based budding (Giemsa stain); **D.** Mold form, septate thin hyphae with tuberculate macroconidia (*arrows showing*)

Source: Public Health Image Library/C. Dr. Lucille K. Georg/ID#:15365, D. Dr. Libero Ajello/ID#:15364/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Histoplasmosis**

Liposomal amphotericin B is the antifungal agent of choice in acute pulmonary and disseminated histoplasmosis. Itraconazole is recommended for chronic cavitary pulmonary histoplasmosis.

H. capsulatum var. duboisii

It causes African histoplasmosis which is clinically distinct; characterized by frequent skin and bone involvement. Its yeast form exists as large thick walled oval yeast cells (7–15 µm) with prominent narrow based budding.

H. capsulatum var. farciminosum

It causes epizootic histoplasmosis. It is a form of lymphangitis in horses and mules.

BLASTOMYCOSIS

Blastomycosis (also known as North American blastomycosis or Gilchrist's disease or Chicago disease) is a fungal infection of humans and other animals, notably dogs and cats, caused by the dimorphic fungus, *Blastomyces dermatitidis*.

Pathogenesis

Blastomycosis is transmitted by inhalation of the conidia of *B. dermatitidis*. The spores enter into the lungs, and are engulfed by alveolar macrophages, where they get converted into yeast phase. This yeast expresses a 120-kDa glycoprotein called **BAD-1** (*B. dermatitidis* adhesin-1) which is an essential virulence factor and also a major inducer of cellular and humoral immune responses.

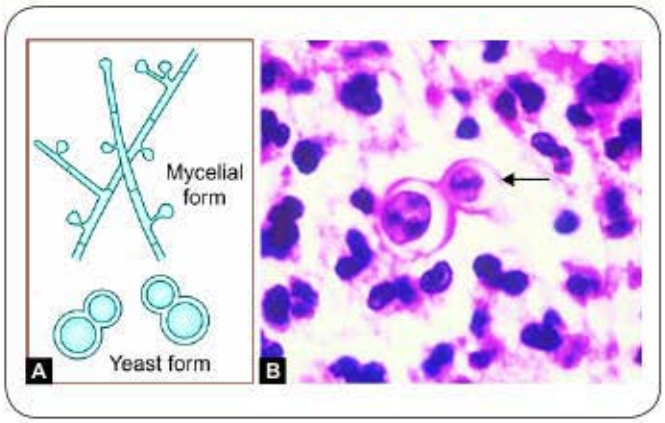
Clinical Manifestations

Acute pulmonary blastomycosis is the most common form. Extrapulmonary manifestations may also occur such as:

- Skin involvement is the most common extrapulmonary form; characterized by either verrucous (more common) or ulcerative type of skin lesions.
- Osteomyelitis may develop along with contiguous soft-tissue abscesses and draining sinuses.
- Prostate and epididymis involvement in men.
- Central nervous sytem (CNS) involvement has been reported in ~40% of AIDS patients. Brain abscess is the usual presentation, followed by cranial or spinal epidural abscess and meningitis.

Epidemiology

Like histoplasmosis, blastomycosis is also endemic in North America, particularly in states bordering the Ohio River and Mississippi River.



Figs 52.14A and B: *Blastomyces* **A.** Schematic (Mycelial and yeast form); **B.** Histopathological stain (*arrow shows*) broad based budding yeast cells (figure of 8 appearance)

Source: B. Public Health Image Library/ID#:493/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Laboratory Diagnosis

- **Histopathological staining** of the tissue biopsy specimens reveals thick-walled round yeast cells of 8–15 µm size with single broad-based budding **(figure of 8** appearance) (Figs 52.14A and B).
- **Culture media** such as SDA, blood agar and BHI agar are inoculated. At 25°C, mycelia form containing hyphae with small pear-shaped conidia are produced; whereas at 37°C mold to yeast conversion takes place.
- **Skin test:** It is done to demonstrate delayed type hypersensitivity to blastomycin antigen.
- **Antibody detection:** Immunodiffusion test specific for *B. dermatitidis* has been developed against yeast phase antigens such as antigen—A, BAD-1 and ASWS antigen (alkali soluble water soluble).
- **Antigen detection assay** to detect *Blastomyces* antigen in urine (more sensitive) and in serum is commercially available.
- **Molecular methods,** including DNA probe hybridization and real time PCR are available.

TREATMENT **Blastomycosis**

Liposomal amphotericin B is the drug of choice in most of the cases. Itraconazole can be given in immunocompetent patients with mild pulmonary or non-CNS extrapulmonary blastomycosis.

COCCIDIOIDOMYCOSIS

Coccidioidomycosis (also called desert rheumatism or Valley fever or California fever), is a systemic fungal disease caused by a dimorphic soil dwelling fungus—*Coccidioides* which has two species, *C. immitis and C. posadasii*.

Pathogenesis

Coccidioides is transmitted by inhalation of arthroconidia. In lungs, they enlarge, become rounded, and develop internal septations to form large sac like structures of size up to 200 µm called **spherules,** that encompass numerous endospores. Spherules may rupture and release packets of endospores that can disseminate and develop into new spherules. If returned to artificial media or the soil, spherules revert back to the mycelial stage.

Clinical Manifestations

Most patients are asymptomatic (60%). In remainders, pulmonary coccidioidomycosis is the most common form; presents as pneumonia, cavities, pleural effusion or nodule formation.

- Skin lesions such as rashes or erythema nodosum and arthritis with joint pain may appear secondary to pulmonary infection particularly in women.
- Disseminated form: Males and persons with low CMI (HIV infected patients with CD4+ T cell count <250/µl) are at higher risk. Common sites for dissemination include skin, bone, joints, soft tissues, and meninges.

Epidemiology

It is endemic in certain parts of Arizona, California, Nevada, New Mexico, Texas, Utah and northern Mexico.

Laboratory Diagnosis

- **Histopathological staining** (H and E stain, PAS or GMS) of sputum or tissue biopsy specimens demonstrates spherules which are large sac like structures (20–80 µm size), have thick, double refractile wall, and are filled with endospores (Figs 52.15A and C).
- **Cultures** on SDA produces mycelial growth, described as fragmented hyphae consisting of **barrel-shaped arthrospores** with alternate cells distorted (empty cells) (Figs 52.15B and D):
  - *Coccidioides* differs from other dimorphic fungi as it grows as mold at both 25°C and 37°C in usual culture media. It forms spherules at 37°C in certain special culture media only.
  - Cultures are highly infectious; may lead to accidental inhalation of spores in laboratories, require biosafety level-3 precautions.
- **Serology:** Antibodies are detected by immunodiffusion test and CFT.
- **Skin test:** It is done by using fungal extracts (coccidioidin or spherulin); if produces at least a 5 mm induration within 48 hours after injection (delayed hypersensitivity reaction) indicates past infection.

TREATMENT **Coccidioidomycosis**

Triazoles such as itraconazole are the drug of choice to treat most cases of coccidioidomycosis, except for diffuse pneumonia with pulmonary sequelae where amphotericin B is recommended.

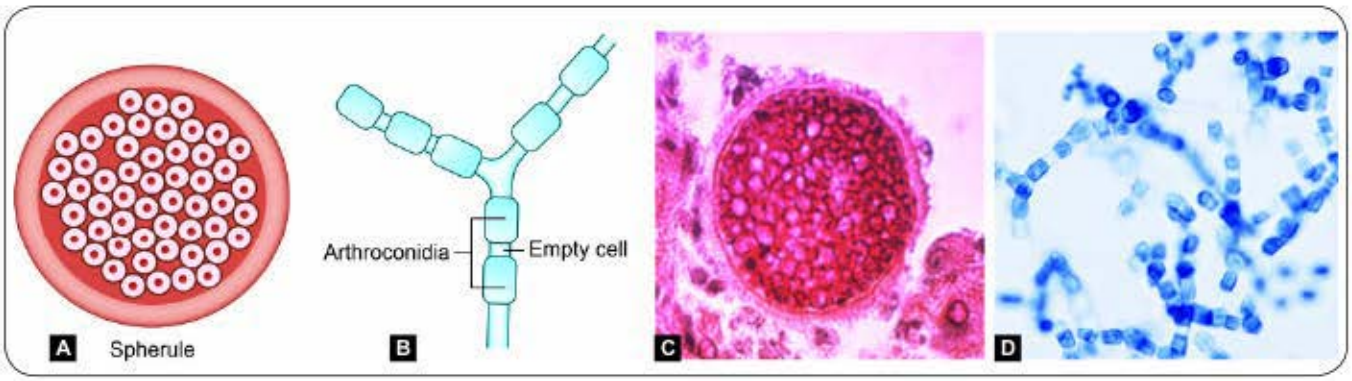
PARACOCCIDIOIDOMYCOSIS

Paracoccidioidomycosis (also known as South American blastomycosis, Lutz-Splendore-de Almeida disease) is a systemic disease caused by the dimorphic fungus—*Paracoccidioides brasiliensis.*

Pathogenesis and Clinical Manifestations

Transmission is by inhalation of spores, which then transform into the yeast phase in lungs. It occurs as two major forms.

1. **Acute form (or juvenile type):** It affects young adults under 30 years age. It is a less common variety, but more severe form, manifests as **disseminated**



Figs 52.15A to D: *Coccidioides* **A.** Spherules (schematic); **B.** Hyphae with arthroconidia (schematic); **C.** Spherules (PAS staining); **D.** Hyphae with arthroconidia (LPCB mount)

Source: Public Health Image Library/C. ID#:14499, D. ID#:12196/Centers for Disease Control and Prevention (CDC) Atlanta. (*with permission*)

infection involving multiple viscera and is refractory to treatment.

2. **Chronic form (or adult form):** It accounts for 90% of cases and predominantly affects older men. It results from reactivation of quiescent lung lesions.
   - It is less severe form, manifested as progressive pulmonary disease affecting lower lobes, with fibrosis.
   - Skin, oral mucosal lesions and cervical lymphadenopathy are the other features.

Epidemiology

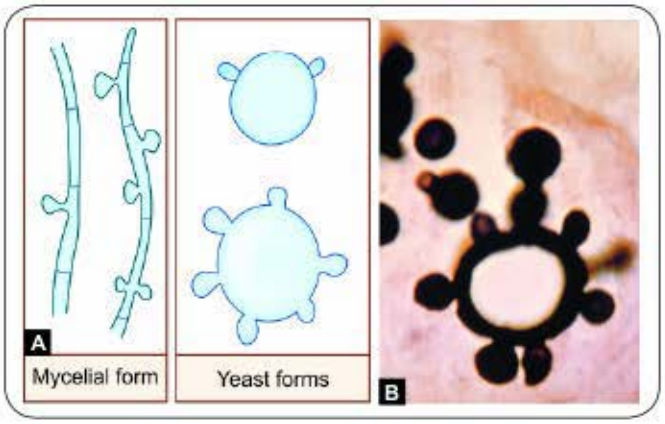
Paracoccidioidomycosis is endemic in Brazil and other South American countries.

Laboratory Diagnosis

- **Histopathological staining** of pus, tissue biopsies or sputum reveals round thick-walled yeasts, with multiple narrow-necked buds attached circumferentially giving rise to **Mickey mouse or pilot wheel** appearance. (Figs 52.16A and B).
- **Culture** on SDA yields mycelial form at 25°C which converts into yeast phase at 37°C when grown in BHI agar supplemented with blood and glutamine.
- **Serology:** Antibodies are detected by immunodiffusion, and most recently by ELISA, using gp43 antigen of *P. brasiliensis*.
- **Skin test:** It demonstrates delayed type hypersensitivity response against paracoccidioidin antigen.

TREATMENT **Paracoccidioidomycosis**

Itraconazole is the treatment of choice for paracoccidioidomycosis, except for the seriously ill patients where amphotericin B is recommended. Sulfonamides are effective, but the response is slow with frequent relapses.



Figs 52.16A and B: Paracoccidioidomycosis. **A.** Schematic representation of mycelial and yeast forms; **B.** Methenamine silver staining shows yeast from (pilot wheel appearance)

Source: B. Public Health Image Library/Dr. Lucille K. Georg/ID#:527/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

OPPORTUNISTIC MYCOSES

Opportunistic mycoses are caused by a group of fungi, which are normally a part of human anatomical flora (e.g. *Candida*) or found in nature and frequently isolated as laboratory contaminants (e.g. *Aspergillus, Rhizopus* and *Penicillium*). However, they are capable of causing infection in presence of opportunities such as low immunity.

CANDIDIASIS

Candidiasis is the most common fungal disease in humans, affecting the skin, mucosa, and various internal organs; caused by *Candida*, a yeast like fungus that produces pseudohyphae. Various species of *Candida* include:

- *Candida albicans:* It is the most common and most pathogenic species of *Candida* infecting humans.
- Other *Candida* species which can occasionally cause infection such as—*C. tropicalis, C. glabrata, C. krusei, C. parapsilosis, C. dubliniensis, C. kefyr, C. guilliermondii* and *C. viswanathii.*

Pathogenesis

Candidiasis is worldwide in distribution, accounts for the most common fungal infection in humans, both in HIV and non-HIV infected people.

Predisposing Factors

Predisposing factors that are associated with increased risk of infection with *Candida* include:

- Physiological state: Extremes of age (infancy, old age), pregnancy.
- Low immunity: Patients on steroid or immunosuppressive drugs, post transplantation, malignancy, HIV infected people.
- Patients on broad spectrum antibiotics—suppresses the normal flora.
- Others: Diabetes mellitus, febrile neutropenia and zinc or iron deficiency.

Virulence Factors

Candida albicans possesses the following virulence factors that contribute to the pathogenesis:

- **Adhesins:** Helps in adhesion to the skin and mucosa.
- **Enzymes** such as aspartyl proteinases and serine proteinases-help in tissue invasion.
- **Toxins:** Glycoprotein extracts of *Candida* cell wall are pyrogenic similar to bacterial endotoxins.
- **Pseudohyphae:** Presence of pseudohyphae indicates active infection; phospholipase released from the hyphal tip may help in invasion, though not proved.
  - *C. albicans* has a unique ability to transform frequently between three phenotypic forms in the

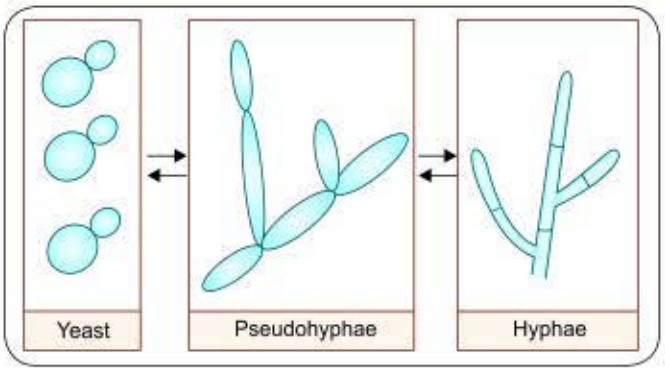


Fig. 52.17: Phenotypic switching of *Candida*

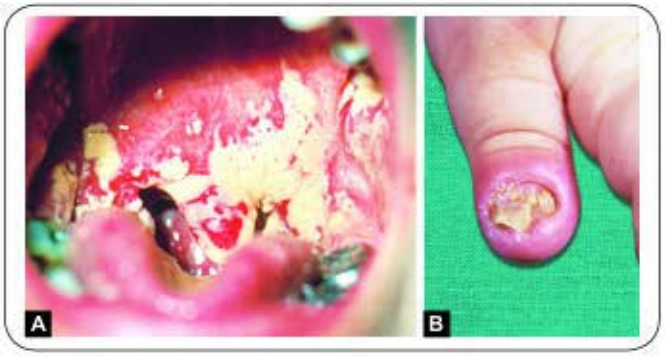
tissue—yeast (blastospores), pseudohyphae, and true hyphae. This property is known as **phenotypic switching (phenotypic dimorphism)**.

- This enables adaptation to changing conditions in host and thereby assists the fungus in evading host defense system (Fig. 52.17).

Clinical Manifestations

Candida species produce a spectrum of infections ranging from skin and mucosal to invasive and allergic infections.

- **Mucosal candidiasis:** The various mucosal manifestations include:
  - Oropharyngeal candidiasis (oral thrush): It presents as white, adherent, painless patches in the mouth (Fig. 52.18A).
  - Candidal vulvovaginitis: It is characterized by pruritus, pain, and vaginal discharge that is usually thin, but may become whitish curd like in severe cases.
  - Balanitis and balanoposthitis (occurring in uncircumcised males).
  - Esophageal candidiasis.
  - Angular stomatitis and denture stomatitis.
  - **Chronic mucocutaneous candidiasis**
    - It is seen in infants and children with deficient CMI (T cell defect).
    - Lesions are produced involving hair, nail, skin, and mucous membrane; which are usually resistant to treatment.
    - It is associated with other endocrine abnormalities.
- **Cutaneous candidiasis:** The following cutaneous manifestations are produced in candidiasis.
  - Intertrigo: It is characterized by erythema and pustules in the skin folds; associated with tight fitting undergarments and sweating.
  - Paronychia (involving nail-skin interface) and onychomycosis (fungal infection of nail) (Fig. 52.18B).
  - Diaper candidiasis: Pustular rashes, associated with use of diapers in infants.
  - Perianal candidiasis.
  - Erosio interdigitalis blastomycetica: It is an infection affecting the web spaces of hands or toes.
  - Generalized disseminated cutaneous candidiasis, seen in infants.
- **Invasive candidiasis:** It results from hematogenous or local spread of the fungi. Various forms are:
  - Urinary tract infection
  - Pulmonary candidiasis
  - Septicemia (mainly by *C. albicans* and *C. glabrata*)
  - Arthritis and osteomyelitis
  - Meningitis
  - Ocular—keratoconjunctivitis and endophthalmitis
  - Hepatosplenic candidiasis
  - Disseminated candidiasis
  - Nosocomial candidiasis (mainly by *C. glabrata*)
- **Allergic candidiasis** includes:
  - **Candidid:** This is an allergic reaction to the metabolites of *Candida*, characterized by vesicular lesions in the web space of hands and other areas, similar to that of dermatophytid reaction (both conditions are together called **'id'** reaction).
  - **Other allergic reactions** include: Gastritis, irritable bowel syndrome and eczema.



Figs 52.18A and B: Candidiasis. **A.** Oral thrush; **B.** Onychomycosis

Source: Public Health Image Library/ A. ID#:1217, B. Mr. Gust, ID#:15669/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

LABORATORY DIAGNOSIS — *Candida albicans*

- **Direct microscopy:** Gram-positive oval budding yeast cells with pseudohyphae.
- **Culture on SDA:** Produces creamy white and pasty colony.
- **Tests for species identification:**
  - Germ tube test (positive for *C. albicans*)
  - Dalmau plate culture for chlamydospore production
  - CHROMagar
  - Growth at 45°C (positive for *C. albicans*)
  - Sugar assimilation test and sugar fermentation test
  - Molecular methods such as PCR
- **Immunodiagnosis:**
  - Antibody detection against cell wall mannan antigen
  - Antigen detection such as cell wall mannan and cytoplasmic antigens
- Enzyme detection, e.g. enolase.
- Detection of metabolites, e.g. mannitol and arabinitol.

Laboratory Diagnosis

Specimen Collection

Depending on the site of infection, various specimens can be collected such as whitish mucosal patches, skin and nail scrapings, sputum, urine or blood.

Direct Microscopy

Gram staining reveals gram-positive oval budding yeast cells (4–6 µm size) with pseudohyphae (Fig. 52.19A). It has to be differentiated from true hyphae (Table 52.10).

Culture

Specimens can be inoculated onto SDA with antibiotic supplements and then incubated at 37°C. *Candida* can also grow in bacteriological culture media such as blood agar. Blood for culture can be inoculated in to blood culture bottles.

- Colonies appear in 1–2 days and described as creamy white, smooth, and pasty with typical yeasty odor (Fig. 52.19B).
- Gram staining of the colonies shows gram-positive budding yeast cells with pseudohyphae except for *C. glabrata* which does not show pseudohyphae.

Tests for Species Identification

- **Germ tube test:** It is a specific test for *C. albicans*; also called Reynolds Braude phenomenon.
  - Colonies are mixed with human or sheep serum and incubated for 2 hours. Wet mount preparation is examined under microscope.
  - Germ tubes are formed, described as long tube like projections extending from the yeast cells.
  - It is differentiated from pseudohyphae as there is no constriction at the origin (Fig. 52.19D, Table 52.10).

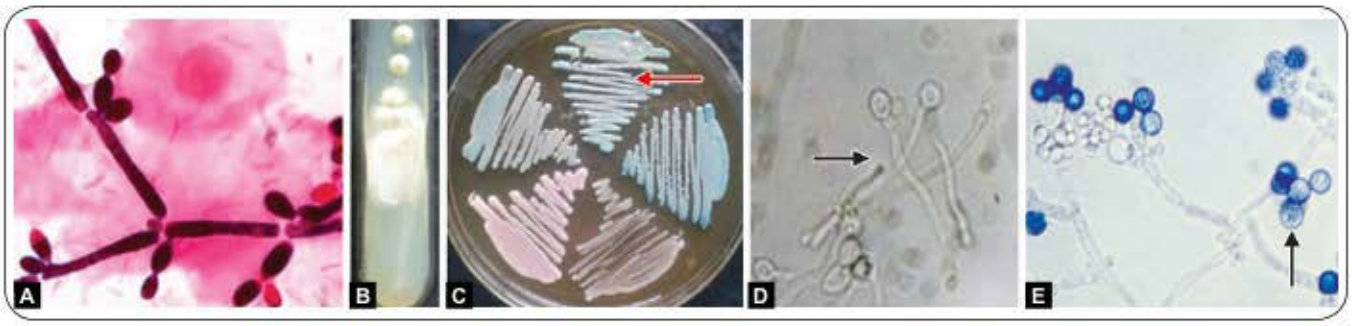
TABLE 52.10: Differences between pseudohyphae and true hyphae

Features	Pseudohyphae	True hyphae
Septa	Constricted	No constriction
Origin of branches	Constricted and septate	▪ No constriction ▪ No septum present
Grows by	Budding	Apical elongation

  - Though the test is specific for *C. albicans*, it may also be positive for *C. dubliniensis*.
- **Dalmau plate culture:** Culture on cornmeal agar can provide clue for species identification. *C. albicans* produces thick walled chlamydospores (Fig. 52.19E).
- **CHROMagar:** Different *Candida* species produce different colored colonies on CHROMagar (Fig. 52.19C).
- **Growth at 45°C:** It differentiates *C. albicans* (grows) from *C. dubliniensis* (does not grow at 45°C).
- **Sugar fermentation test** and **sugar assimilation test** can differentiate between various *Candida* species.
- **Molecular methods** such as PCR using species specific primers are useful for species identification.

Immunodiagnosis

- **Antibody detection:** Various formats like ELISA, latex agglutination tests are available detecting serum antibodies against cell wall mannan antigen.
- **Antigen detection:** *Candida* specific antigen such as cell wall mannan and cytoplasmic antigens can be detected by ELISA.
- **Enzyme detection:** Assays are available to detect enzymes specific for *Candida* such as enolase, aspartate proteinase, etc.
- **Test for metabolites:** Specific metabolites of *Candida* such as mannitol, arabinitol can be detected. G test is done for detection of α1-3 glucan.



Figs 52.19A to E: A. *Candida albicans*—gram-positive oval budding yeast cells with pseudohyphae; **B.** *Candida albicans* on SDA shows creamy white colonies; **C.** CHROMagar showing colonies of various *Candida* species producing different colors (e.g. light-green color by *C. albicans*, red arrow); **D.** *Candida albicans* shows positive germ tube test (arrow showing); **E.** *Candida albicans* shows thick walled chlamydospores (arrow showing)

Source: Public Health Image Library/A. ID#:2934; E. Dr. Godon Roberstad/ID#:2917/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT **Candidiasis**

The antifungal drugs recommended depends upon the type of candidiasis.

- Cutaneous candidiasis or oral thrush: the drug of choice is topical azole.
- Esophageal and vulvovaginal candidiasis: the drug of choice is oral fluconazole.
- Disseminated candidiasis: the drug of choice is amphotericin B.

C. glabrata and *C. krusei* exhibit intrinsic resistance to azoles and are refractory to treatment with azoles.

CRYPTOCOCCOSIS

Cryptococcosis is caused by a capsulated yeast called *Cryptococcus neoformans*, which is capable of producing potentially fatal meningitis in HIV infected people.

Species and Serotypes

Cryptococcus has two species, *C. neoformans* and *C. gattii* and four serotypes A, B, C and D.

- *C. neoformans* occurs in two varieties—*C. neoformans* var. *grubii* and *C. neoformans* var. *neoformans*; which correlate with serotypes A and D, respectively.
- *C. gattii* is antigenically diverse and corresponds to the serotypes B and C.
- Most laboratories do not routinely distinguish between the types, and report all isolates simply as *C. neoformans*.

Pathogenesis

Infection is acquired by inhalation of aerosolized forms of *Cryptococcus*. Both yeast cells as well as basidiospores (the sexual stage of *Cryptococcus*) are infectious.

- In immunocompetent individuals, the lungs exhibit defence mechanisms which usually limit the infection.
- However, in people with low immunity, pulmonary infection occurs followed by dissemination through blood.
- **CNS spread:** The unique feature of *Cryptococcus* is its ability to cross blood-brain barrier which occurs by the yeast cells either they migrate directly across the endothelium or carried inside the macrophages as "Trojan horse".
- **Virulence factors** of *Cryptococcus* that favor invasion and spread of infection include:
  - Polysaccharide capsule—It is the principal virulence factor of the fungus. It is antiphagocytic and also inhibits the host's local immune responses.
  - Ability to make melanin by producing an enzyme called phenyl oxidase.
  - Production of other enzymes such as phospholipase and urease.
- **Risk factors:** Individuals at high risk for cryptococcosis include:
  - Patients with advanced HIV infection with CD4 T cell counts less than 200/µl: They are at high risk of acquiring *C. neoformans* infection. However, *C. gattii* is not associated with HIV infection. It usually causes infection in immunocompetent individuals.
  - Patients with hematologic malignancies
  - Transplant recipients
  - Patients on immunosuppressive or steroid therapy.

Clinical Manifestations

Various clinical manifestations of cryptococcosis include:

- Pulmonary cryptococcosis: It is the first and the most common presentation.
- Cryptococcal meningitis: It presents as chronic meningitis, with headache, fever, sensory and memory loss, cranial nerve paresis and loss of vision (due to optic nerve involvement).
- Skin lesions: They are commonly seen with *C.neoformans* var. *neoformans* (serotype D).
- Osteolytic bone lesions.

Epidemiology

Worldwide, cryptococcosis accounts for nearly 1 million cases, with more than 600,000 deaths annually.

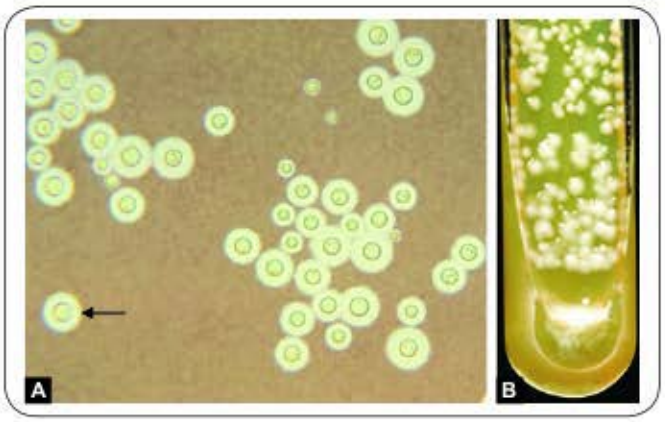
- **Geographical distribution:** *C. neoformans* var. *grubii* (serotype A) strains are found worldwide; however, *C. neoformans* var. *neoformans* (serotype D) strains are restricted to Europe and *C. gattii* is confined to tropics; outbreaks occurred in Vancouver in 1999.
- **Habitat:** *C. neoformans* is frequently found in soils contaminated with avian excreta and pigeon droppings. In contrast, *C. gattii* inhabits in eucalyptus tree.

Laboratory Diagnosis

Specimens such as CSF, blood or skin scrapings can be collected.

Direct Detection Methods

- **Negative staining:** Modified India ink stain (added with 2% mercurochrome) and nigrosin stain are used to demonstrate the capsule, which appears as refractile delineated clear space surrounding the round budding yeast cells against black background.
  - Capsules may be twice as thick as the diameter of yeast cells (Fig. 52.20A).
  - India ink stain is less sensitive (60–70%).
- **Gram staining** may show gram-positive round budding yeast cells.
- **Other stains include:**
  - Mucicarmine stain: It stains the carminophilic cell wall of *C. neoformans*.
  - Masson-fontana stain: It demonstrates the production of melanin.
  - Alcian blue stain to demonstrate the capsule.



Figs 52.20A and B: *Cryptococcus neoformans*. **A.** India ink staining shows clear refractile capsules surrounding round budding yeast cells; (arrow showing) **B.** Growth on SDA at 37°C—shows creamy white mucoid colonies

Source: Public Health Image Library/A. Dr. Leanor Haley, ID#:3771 B. Dr. William Kaplan, ID#:3199/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

- **Antigen detection:** The capsular antigens can be detected from CSF or serum by latex agglutination test. It is a rapid and sensitive (95% sensitivity) and specific method.

Culture

CSF is inoculated onto SDA without antibiotics, blood agar or chocolate agar and incubated at 37°C. Blood is inoculated in biphasic blood culture bottles. Colonies appear as mucoid creamy white and yeast like (Fig. 52.20B).

Confirmation of *Cryptococcus* species is made by:

- Niger seed agar and bird seed agar: They are used to demonstrate melanin production (brown colored colonies).
- Growth at 37°C
- Urease test is positive
- Assimilation of inositol and nitrate
- Mouse pathogenicity test

TREATMENT — Cryptococcosis

Treatment depends upon the type of cryptococcosis.

- Cryptococcosis without CNS involvement: Fluconazole is the drug of choice.
- HIV-infected patients with CNS involvement: The recommended regimen is induction phase for two weeks (amphotericin B ± flucytosine) followed by lifelong maintenance therapy with fluconazole.

ZYGOMYCOSIS

Zygomycosis represents group of life-threatening infections caused by aseptate fungi belonging to the phylum Zygomycota. Agents of zygomycosis fall into two orders:

1. Order mucorales (causes mucormycosis)
   - *Rhizopus* (*R. oryzae* and *R. microsporus*)
   - *Mucor racemosus*
   - *Rhizomucor pusillus*
   - *Absidia corymbifera*
   - *Apophysomyces elegans*
2. Order entomophthorales (causes entomophthoromycosis)
   - *Basidiobolus ranarum*
   - *Conidiobolus coronatus*

Mucormycosis

Pathogenesis

Spores of fungi causing mucormycosis are found ubiquitously in the environment. Transmission occurs via inhalation, inoculation or rarely ingestion of spores. Spores develop into mycelial form containing wide aseptate hyphae which are angioinvasive in nature resulting in spread of infection.

Predisposing factors: Agents of mucormycosis require iron as growth factor. Hence conditions with increased iron load are at higher risk of developing invasive mucormycosis.

- Diabetic ketoacidosis (DKA) is the most important risk factor. Acidosis causes release of iron from the sequestered proteins in serum.
- End stage renal disease.
- Patients taking iron therapy or deferoxamine (iron chelator).
- Defects in phagocytic functions (e.g. neutropenia or steroid therapy).

Clinical Manifestations

Agents of mucormycosis are angioinvasive in nature. Mucormycosis has six types of clinical presentations.

1. **Rhinocerebral mucormycosis:** It occurs commonly in patients with diabetic ketoacidosis. It is the most common form; starts as eye and facial pain, may progress to cause orbital cellulitis, proptosis and vision loss (Figs 52.21A and B).
2. Pulmonary mucormycosis is the second most common form, occurs in patients with leukemia.
3. Cutaneous mucormycosis.
4. Gastrointestinal mucormycosis such as necrotizing enterocolitis; seen commonly in premature neonates.
5. Disseminated mucormycosis: Brain is the most common site of dissemination, but can affect any organ.
6. Miscellaneous forms: Any body site may be randomly affected such as bones, trachea and kidneys, etc.

Figs 52.21A and B: Mucormycosis manifestations. **A.** Orbital cellulitis; **B.** Proptosis

Source: Public Health Image Library/A. Dr. Thomas F. Sellers, ID#:2831, B. Lucille K. Georg. ID#:14554 /Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

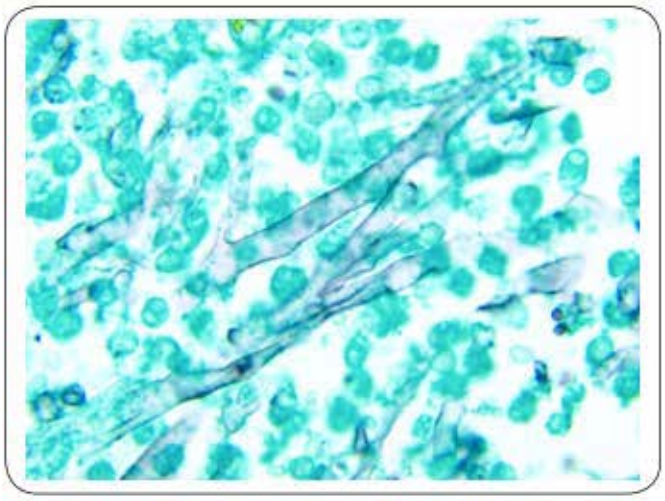


Fig. 52.22: Zygomycosis—histopathology of tissue section shows aseptate broad hyphae (Methenamine silver stain)

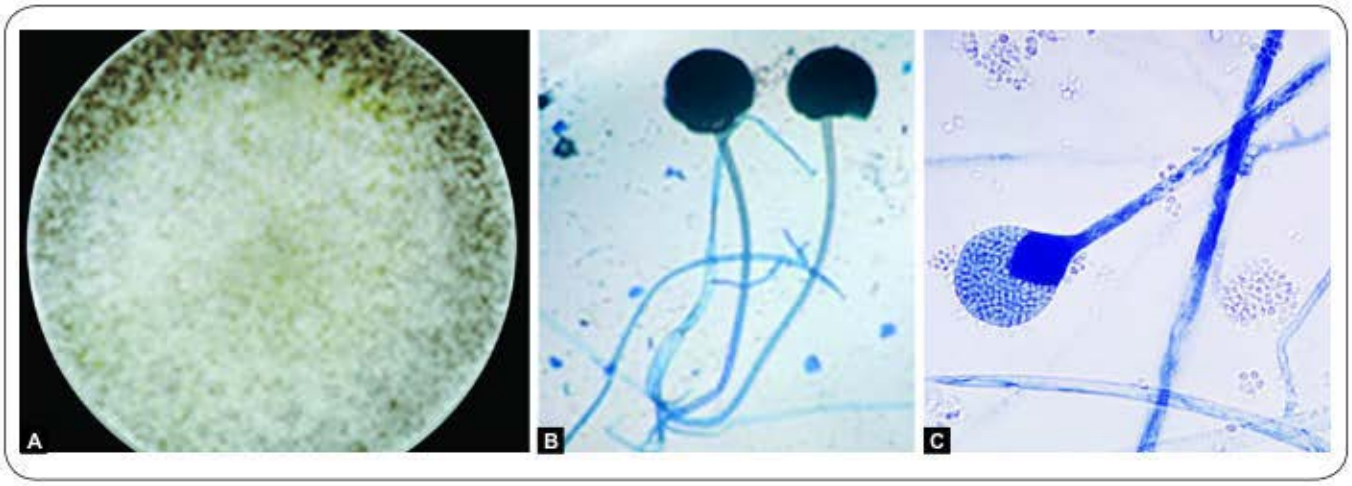
Source: Public Health Image Library/Dr. Libero Ajello, ID#:4234/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

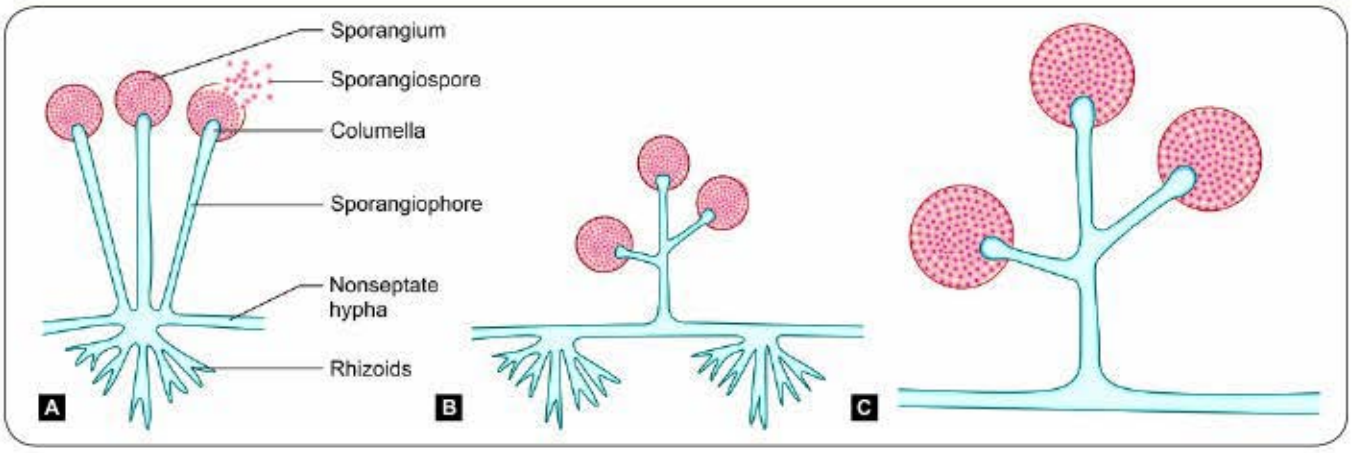
Laboratory Diagnosis

- **Histopathological staining** of tissue biopsies shows broad aseptate hyaline hyphae with wide angle branching (Fig. 52.22).
- **Culture on SDA at 25°C:** Reveals characteristic white cottony woolly colonies with tube filling growth (hence called **lid lifters**). In some species, e.g. *Rhizopus* the colonies become brown black later, due to sporulation giving rise to **salt and pepper** appearance (Fig. 52.23A).
- **Microscopic appearance:** LPCB mount of the colonies reveals broad aseptate hyaline hyphae, from which sporangiophore arises and then ending at sporangium which contains numerous sporangiospores (Figs 52.23B, C and 52.24).
- **Rhizoid:** Some species bear a unique root like growth arising from hyphae called rhizoid which provides initial clue for identification of the fungus. Species can be differentiated depending on the position of the rhizoid with respect to sporangiophore (Fig. 52.24).
  - *Rhizopus* bears nodal rhizoid
  - *Absidia* bears internodal rhizoid
  - *Mucor*: rhizoid is absent.



Figs 52.23A to C: *Rhizopus*. **A.** Macroscopic (salt and pepper appearance colony); **B.** Microscopic (LPCB mount); **C.** Mucor; (LPCB mount) shows sporangium, rhizoid present

Source: C. Public Health Image Library/ Dr. Lucille K. Georg, ID#:3960/Centres for Disease Control and Prevention (CDC), Atlanta (*with permission*)



Figs 52.24A to C: Microscopic schematic diagram. **A.** *Rhizopus;* **B.** *Absidia;* **C.** *Mucor*

TREATMENT **Zygomycosis**

Amphotericin B deoxycholate remains the drug of choice for all forms of mucormycosis except the mild localized skin lesions in immunocompetent patients, which can be removed surgically.

Entomophthoromycosis

This includes the subcutaneous lesions produced by members of order Entomophthorales, i.e. *Conidiobolus* and *Basidiobolus;* the latter is also associated with visceral involvement.

ASPERGILLOSIS

Aspergillosis refers to the invasive and allergic diseases caused by a hyaline mold named *Aspergillus*. There are nearly 35 pathogenic and allergenic species of *Aspergillus,* important ones being—*A. fumigatus, A. flavus* and *A. niger.*

Pathogenesis

Aspergillus species are widely distributed in nature, most commonly growing on decaying plants, producing chains of conidia. Transmission occurs by inhalation of airborne conidia.

Risk factors for invasive aspergillosis are:

- Glucocorticoid use (the most important risk factor)
- Profound neutropenia
- Neutrophil dysfunction
- Underlying pneumonia, chronic obstructive pulmonary disease, tuberculosis or sarcoidosis
- Anti-tumor necrosis factor therapy.

Clinical Manifestations

The incubation period varies from 2 to 90 days. Depending up on the site of involvement, *Aspergillus* produces various clinical manifestations such as:

- **Pulmonary aspergillosis:** It is the most common form of aspergillosis; includes various manifestations such as:
  - Allergic bronchopulmonary aspergillosis (ABPA)
  - Severe bronchial asthma
  - Extrinsic allergic alveolitis
  - Aspergilloma (fungal ball)
  - Acute angio-invasive pulmonary aspergillosis
  - Chronic cavitary pulmonary aspergillosis
- **Other forms of aspergillosis include:**
  - Invasive sinusitis
    - Invasive sinusitis (acute and chronic from)
    - Chronic granulomatous sinusitis
    - Maxillary fungal ball
    - Allergic fungal sinusitis
  - Cardiac aspergillosis: Endocarditis (native or prosthetic) and pericarditis
  - Cerebral aspergillosis: Brain abscess, hemorrhagic infarction, and meningitis
  - Ocular aspergillosis: Keratitis and endophthalmitis
  - Ear infection: Otitis externa
  - Cutaneous aspergillosis: Direct invasion of the skin occurs in neutropenic patients at the site of IV catheter insertion and in burns patients.
  - Nail bed infection: Onychomycosis.
  - Mycotoxicosis: Various *Aspergillus* species produce several fungal toxins; e.g. *A. flavus* produces aflatoxin, which causes liver carcinoma (see Table 52.12).

Clinical manifestations also depend on the species involved:

- *A. fumigatus* accounts for most of the cases of acute pulmonary and allergic aspergillosis.
- *A. flavus* is more common in hospitals and causes more sinus, skin and ocular infections than *A. fumigatus*.
- *A. niger* can cause invasive infection but more commonly colonizes the respiratory tract and causes otitis externa.

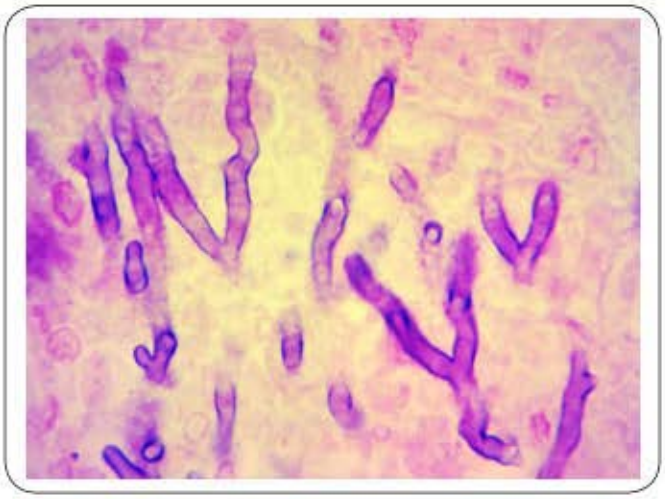


Fig. 52.25: Hematoxylin-eosin stained (H and E) lung section shows septate narrow hyphae—confirms invasive aspergillosis

Source: Public Health Image Library/Armed Forces Institute of Pathology; Dr. Hardin, ID#:15630/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TABLE 52.11: Identification features of *Aspergillus* species

Aspergillus species	Macroscopic appearance of colony	Microscopic appearance of colony (LPCB mount)
A. fumigatus (Figs 52.26A, 52.27A, 52.28A)	Colonies—smoky green, velvety to powdery, reverse is white	▪ Vesicle is conical-shaped. ▪ Phialides are arranged in single row ▪ Conidia arise from upper third of vesicle ▪ Conidia are hyaline
A. flavus (Figs 52.26B, 52.27B, 52.28B)	Colonies—yellow green, velvety, reverse is white	▪ Vesicle is globular-shaped ▪ Phialides in one or two rows ▪ Conidia arise from entire vesicle ▪ Conidia are hyaline
A. niger (Figs 52.26C, 52.27C, 52.28C)	Colonies—black, cottony type, reverse is white	▪ Vesicle is globular-shaped ▪ Phialides in two rows ▪ Conidia arise from entire vesicle ▪ Conidia are black

Laboratory Diagnosis

Specimens such as sputum and tissue biopsies may be collected.

Direct Examination

KOH (10%) mount or histopathological staining (Fig. 52.25) of specimens reveals characteristic narrow septate hyaline hyphae with acute angle branching.

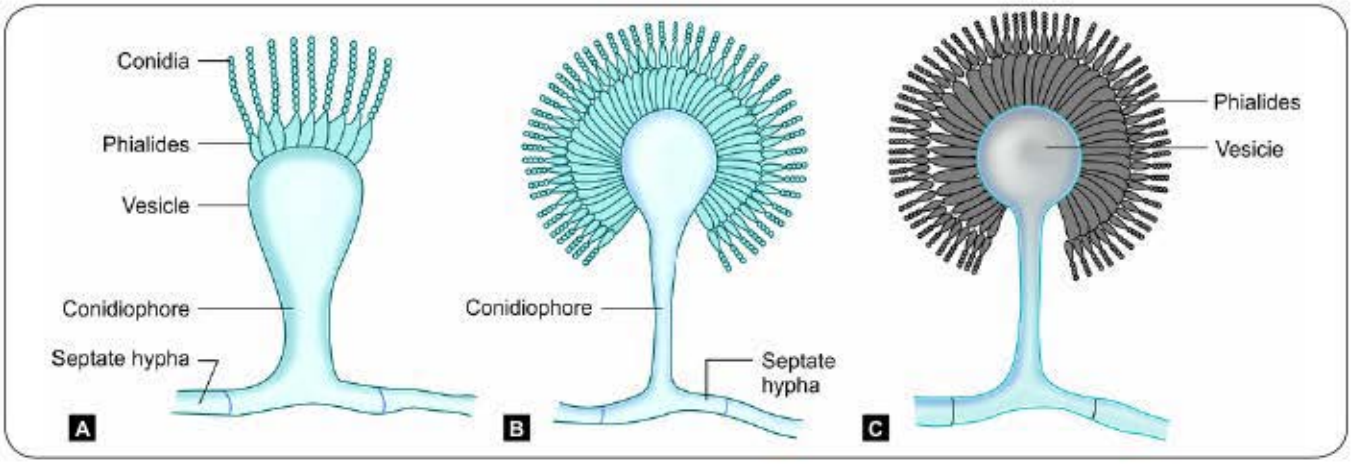
Culture

Specimens are inoculated onto SDA and incubated at 25°C. Species identification is done based on macroscopic and microscopic (LPCB mount) appearance of the colonies (Table 52.11).

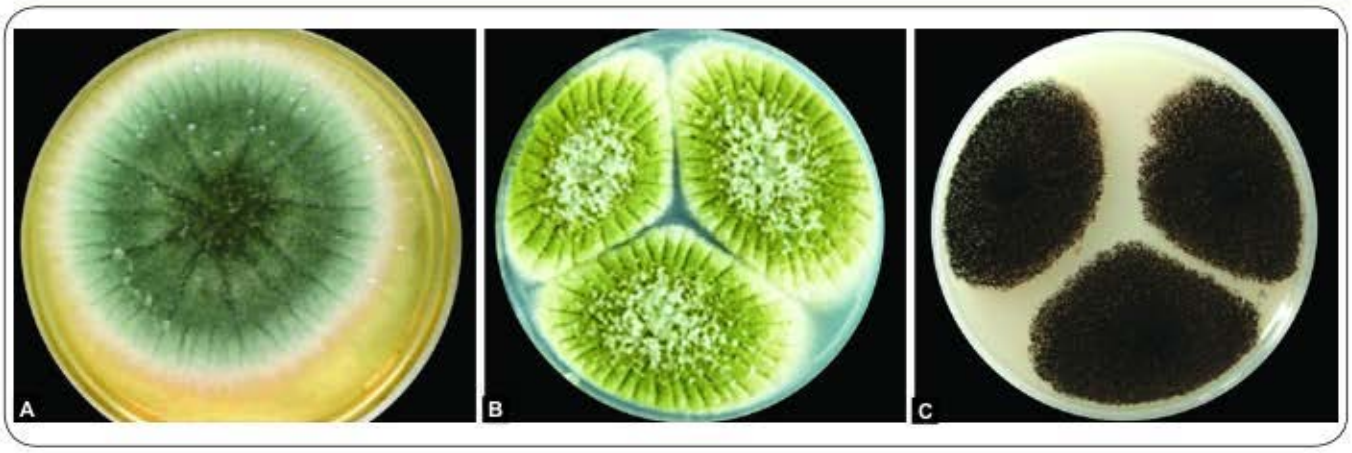
- Colonies consist of hyaline septate hyphae from which conidiophores arise which end at vesicles. Vesicles are either tubular or globular in shape.
- From the vesicle, finger-like projections of conidia producing cells arise called **phialides** or **sterigmata**. Phialides are arranged either in one or two rows, the first row is called **metulae**.
- Conidia arise from the vesicles either on their entire surface or only on the upper half (Figs 52.26A to C and Table 52.11).

Antigen Detection

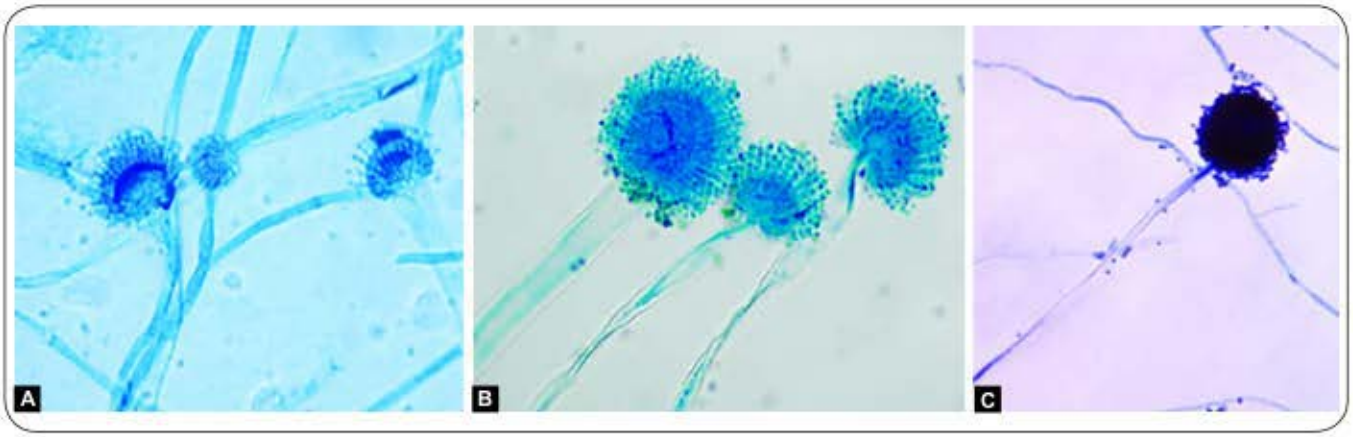
ELISA detecting *Aspergillus* specific galactomannan antigen in patient's sera or urine is useful for establishing early diagnosis.



Figs 52.26A to C: Conidiation of various *Aspergillus* species. **A.** *A. fumigatus*; **B.** *A. flavus*; **C.** *A. niger*



Figs 52.27A to C: *Aspergillus* (colonies on SDA). **A.** *Aspergillus fumigatus*; **B.** *Aspergillus flavus*; **C.** *Aspergillus niger*



Figs 52.28A to C: *Aspergillus* microscopic picture (LPCB mount). **A**. *Aspergillus fumigatus*; **B.** *Aspergillus flavus*; **C.** *Aspergillus niger*

Antibody Detection

- Detection of serum antibodies is very useful for chronic invasive aspergillosis and aspergilloma, where the culture is usually negative. Titer falls rapidly following clinical improvement.
- In allergic syndromes such as ABPA and severe asthma, specific serum IgE levels are elevated.

Detection of Metabolites

Detection of α1-3 glucan (by G test) or mannitol (by gas liquid chromatography) is useful alternative for establishing the diagnosis, particularly when the culture is negative.

Skin Test

Positive skin test to various antigen extracts of *Aspergillus* indicates hypersensitivity response and is usually positive for various allergic type of aspergillosis.

TREATMENT **Aspergillosis**

Following are the first line treatment recommended in different forms of aspergillosis.

- For invasive aspergillosis—voriconazole is the drug of choice.
- For ABPA—itraconazole is the drug of choice.
- For single aspergilloma—surgery is indicated.
- For chronic pulmonary aspergillosis—itraconazole or voriconazole is the drug of choice.
- For prophylaxis, posaconazole is indicated.

PENICILLIOSIS

Penicilliosis denotes the group of infections caused by pathogenic *Penicillium* species.

Clinical Significance

Penicillium has more than 250 species, most are found as saprophytes in the environment. However, some species are associated with human diseases such as:

TABLE 52.12: Features of common mycotoxins

Mycotoxin	Produced by fungal species	Source	Clinical condition
Aflatoxin	*Aspergillus flavus* *Aspergillus parasiticus, A. nomius* *Penicillium puberulum*	Nuts, maize	Hepatoma, hepatitis Indian childhood cirrhosis Reye's syndrome
Fumonisins	*Fusarium moniliforme*	Maize	Equine leukoencephalomalacia Porcine pulmonary edema Carcinoma esophagus
Trichothecenes	*Fusarium graminearum*	Maize, wheat, sorghum	Alimentary toxic aleukia Biological warfare (yellow rain)
Ochratoxin	*Aspergillus ochraceus, A. niger* *Penicillium verrucosum*	Cereals, bread	Nephropathies (Balkan endemic nephropathy)
Cyclopiazonic acid	*Aspergillus flavus, A. versicolor, A. oryzae* *Penicillium cyclopium*	Groundnut, corn	Kodua poisoning Co-contaminant with aflatoxin
Zearalenones	*Fusarium graminearum*	Wheat, maize	Genital disorder in pigs

- *Penicillium marneffei* (a dimorphic fungus, described later).
- Mycotoxicoses is caused by toxins released by certain species of *Penicillium* such as *P. cyclopium, P. verrucosum* and *P. puberulum* (Table 52.12).
- Other *Penicillium* species are usually found in environment and are isolated as common laboratory contaminants. Rarely they are associated with human diseases such as:
  - Invasive penicilliosis: e.g. endophthalmitis and endocarditis.
  - Superficial disease: Such as otomycosis, keratitis and onychomycosis.
  - Allergic disease: e.g. asthma and allergic pneumonitis.

Laboratory Diagnosis

Except for *P. marneffei* which is a dimorphic fungus, all other *Penicillium* species occur only as molds, can grow easily on SDA at 25°C.

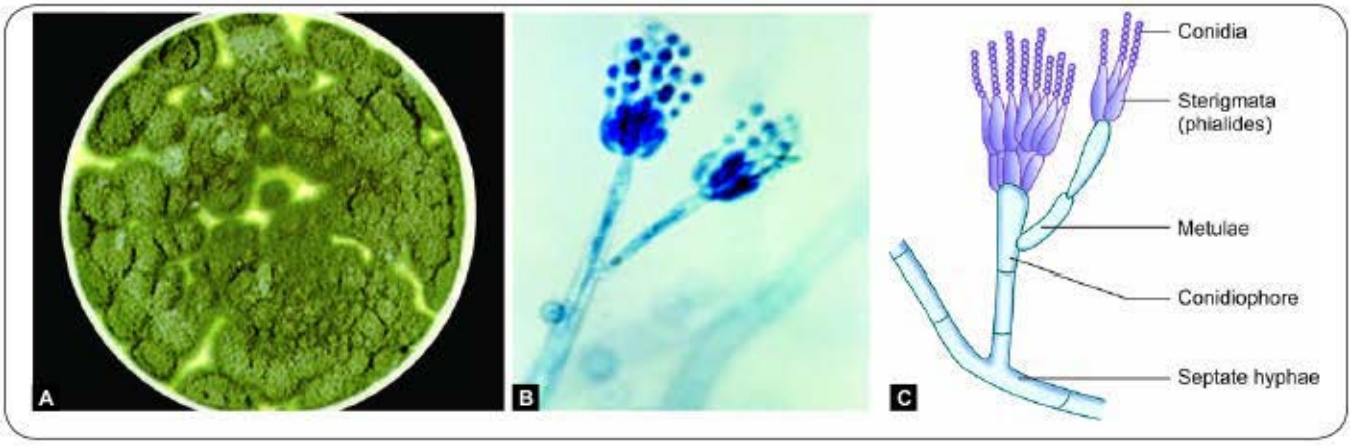
- **Colonies** are rapid growing, flat with velvety to powdery texture and greenish in color (Fig. 52.29A).
- **Microscopic appearance:** LPCB mount of the colonies reveals hyaline thin septate hyphae, and the vesicles are absent. The conidiophore directly divides into elongated metulae, from which flask shaped phialides originate which bear chain of conidia. Such an arrangement is called as **brush border appearance** (Figs 52.29B and C).

Penicillium marneffei

Penicillium marneffei is a thermally dimorphic fungus that causes opportunistic infection in HIV infected patients.

Epidemiology

P. marneffei is endemic in south East Asian countries including Thailand, Vietnam and India (Manipur).



Figs 52.29A to C: *Penicillium* species. **A.** Colonies on SDA; **B.** Microscopic picture (LPCB mount); **C.** Schematic microscopic picture

Source: B. Public Health Image Library/Lucille Georg, ID#:8398/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

Pathogenesis

P. marneffei is found mostly in rural areas where the bamboo rats are prevalent, which are the reservoirs of infection; however, there is no direct rat to man transmission.

- Immunocompromised hosts (e.g. patients with advanced AIDS) are at higher risk.
- Transmission is by inhalation of conidia from the environment.
- Mold to yeast conversion occurs in the lungs and then the yeast form spreads via blood to the reticuloendothelial system.

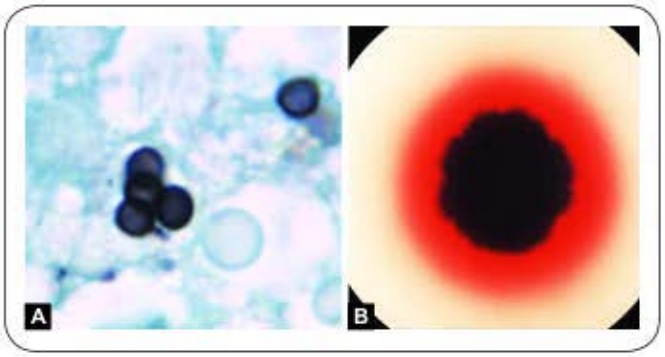
Clinical Manifestations

P. marneffei produces two types of clinical manifestations.

1. **Systemic infection:** The manifestations are similar to that of disseminated histoplasmosis such as fever, weight loss, dyspnea, lymphadenopathy and hepatosplenomegaly.
2. **Skin lesions:** Warty lesions mimicking that of molluscum contagiosum are seen.

Laboratory Diagnosis

- **Histopathological staining** of tissue sections, skin scrapings or blood smear shows **oval or elliptical yeast cells with central septation**, which indicates that these cells divide by transverse fission rather than budding (Fig. 52.30A).
- **Culture:** *P. marneffei* being dimorphic; produces yeast like colonies at 37°C and mold form at 25°C.
- The mold form has a characteristic **brick red pigment** (Fig. 52.30B), but the microscopic appearance of mold form is similar to other *Penicillium* species.



Figs 52.30A and B: *Penicillium marneffei*. **A.** Methenamine silver staining shows yeast cells with central septations; **B.** Red pigmented colony (mold form)

Source: Public Health Image Library/Dr. Libero Ajello, A. ID#:11959 and B. ID#:11967/Centers for Disease Control and Prevention (CDC), Atlanta (*with permission*)

TREATMENT — Penicilliosis

AIDS patients with severe penicilliosis are treated with amphotericin B till the condition improves followed by maintenance therapy with itraconazole for 12 weeks. In mild penicilliosis, itraconazole is recommended for 12 weeks.

PNEUMOCYSTIS PNEUMONIA

Pneumocystis pneumonia (PcP) has been increasingly reported after the discovery of HIV/AIDS.

Taxonomy

Recently the taxonomy of *Pneumocystis* has been changed (2002). Once thought to be a protozoan, now it is classified under fungus based on nucleic acid sequence studies.

- Taxonomists renamed the human species of *Pneumocystis* as *Pneumocystis jirovecii*.
- The previously used species name *P. carinii* has been assigned to describe the rat species of *Pneumocystis*.

Pathogenesis

Like protozoa, *Pneumocystis* exists in cyst and trophozoite forms. The cysts are found in environment, where as in human tissues both cysts and trophozoites (containing 4–8 sporozoites) are found.

Once inhaled, the cysts are carried to the lungs where they transform into the trophozoite stage. The trophozoites induce an inflammatory response, that leads to recruitment of plasma cells resulting in formation of **frothy exudate** filling the alveoli. Hence, this condition is also called **plasma cell pneumonia**.

Laboratory Diagnosis

Histopathological examination of lung tissue or fluids obtained by bronchoscopy, bronchial lavage, or open lung biopsy reveals **cysts**.

- Gomori's methenamine silver (GMS) staining is the method of choice to demonstrate the cysts of *P. jirovecii*. The cysts resemble black colored **crushed ping-pong balls**, against the green background (Fig. 52.31).
- *Pneumocystis* is not cultivable and there is no serological test available.
- PCR assay has been developed for detection of *P. jirovecii* specific genes.

TREATMENT — *Pneumocystis* pneumonia

Cotrimoxazole (trimethoprim/sulfamethoxazole) is the drug of choice for *Pneumocystis* pneumonia. It is given for 14 days in non-HIV patients and 21 days in patients with HIV. It is also the recommended drug for primary and secondary prophylaxis in patients with HIV.

FUSARIOSIS

Pathogenesis

Fusarium species are soil and plant saprophytes found worldwide. They rarely cause human infections.

- In immunocompetent individuals, they cause:
  - Keratitis in contact lens wearers
  - Onychomycosis
- In immunocompromised patients—they are angioinvasive and cause pulmonary and sinus infection.
- In patients with neutropenia and hematologic malignancies, disseminated fusariosis occurs with frequent skin lesions.

Laboratory Diagnosis

Fusarium is a filamentous fungus, grows rapidly on SDA at 25°C and produces woolly to cottony, flat, spreading white to pink colonies. LPCB mount of the colony reveals hyaline septate hyphae bearing round microconidia, sickle shaped large macroconidia and chlamydospores (Fig. 52.32).

TREATMENT **Fusariosis**

Fusarium species are resistant to many antifungal agents. Liposomal amphotericin B, voriconazole or posaconazole are recommended.

MYCOTOXICOSES

Mycotic poisoning can be classified into two varieties:

1. **Mycotoxicosis:** Refers to the disease produced following consumption of food contaminated by toxins liberated by certain fungi (Table 52.12).
2. **Mycetism:** Refers to the toxic effects produced by eating poisonous fleshy fungi; usually different types of mushrooms (Table 52.13).

TABLE 52.13: Features of common mycetism

Mushroom poisoning	Produced by fungal species	Source	Clinical condition
Ergot alkaloid	*Claviceps purpurea*	Rye flour	St. Anthony's fire
Coprine poisoning	*Coprine atrementarius*	Butter	Antabuse like reaction
Muscarine	*Inocybe fastigiata*	Food	Cholinergic effect
Ibotenic acid, muscimol	*Amanita pantherina*	Edible mushroom	Abdominal pain, vomiting, diarrhea
Cyclopeptide	*Amanita phalloides*	Edible mushroom	Hepatocellular failure, green death cap

EXPECTED QUESTIONS

I. Essay:

1. Ranjit, a 29-year-old HIV-infected male presents to the clinic with a 5-day history of a mild burning sensation in his mouth that is accentuated when eating acidic or spicy foods. The oral examination showed creamy white patches on the oral mucosa. Scraping obtained from the patches revealed gram-positive budding yeast cells with pseudohyphae.
   a. What is the clinical diagnosis and the likely etiological agent?
   b. Name the risk factors predisposing for this condition.
   c. What are the other clinical manifestations caused by this organism?
   d. Describe the laboratory diagnosis of this clinical condition in detail?
2. A 21-year-old male had developed characteristic well-demarcated annular or ring shaped pruritic scaly skin lesions with central clearing and raised edges. Culture of the skin scraping done on Sabaouraud's dextrose agar reveals velvety colonies with red pigment on the reverse. Microscopy of the culture isolate reveals plenty of tear drop shaped microconidia and few, long, pencil shaped macroconidia.
   a. What is the clinical diagnosis and what is the most likely etiological agent?
   b. Describe the various clinical manifestations produced by this organism?
   c. Add a note on the laboratory diagnosis of this condition.
3. Classify various types fungal diseases. Describe the aetiology, clinical manifestations and laboratory diagnosis of mycetoma.

II. Write short notes on:

1. Cryptococcosis
2. Histoplasmosis
3. Dimorphic fungi
4. Mucormycosis
5. *Pneumocystis* pneumonia (PcP)
6. Aspergillosis

III. Multiple Choice Questions (MCQs):

1. All are yeast or yeast like fungi except:
   a. *Candida*
   b. *Geotrichum*
   c. *Cryptococcus*
   d. *Trichophyton*

2. Fungi which do not have sexual stage:
   a. Zygomycota
   b. Ascomycota
   c. Basidiomycota
   d. Fungi imperfecti

3. Organism that does not affect nail:
   a. *Trichophyton*
   b. *Epidermophyton*
   c. *Microsporum*
   d. *Candida albicans*

4. A patient coming from Himachal Pradesh, presents with multiple skin lesions. Microscopy reveals cigar shaped yeast cells and asteroid bodies. Microscopy of culture shows 'flower like' pattern. Identify the agent?
   a. *Candida*
   b. *Sporothrix schenckii*
   c. *Epidermophyton floccosum*
   d. *Rhizopus*

5. Germ tube test is diagnostic for:
   a. *Candida glabrata*
   b. *Candida albicans*
   c. *Cryptococcus neoformans*
   d. *Coccidioides immitis*

6. Example for fungus having branching, aseptate hyphae are all except:
   a. *Rhizopus*
   b. *Absidia*
   c. *Penicillium*
   d. *Mucor*

7. Most common fungus causing orbital cellulitis in a patient with diabetic ketoacidosis is:
   a. *Mucor*
   b. *Aspergillus*
   c. *Candida*
   d. *Cryptococcus*

  - Prebiotics

INTRODUCTION

Normal flora (also called "indigenous microbiota") refers to the diverse group of microbial population that every human being harbors on his/her skin and mucous membranes.

- In humans, the normal flora is located in various sites such as gastrointestinal tract (GIT), respiratory tract, genitourinary tract and skin.
- Although there are many species of normal flora, these microbes typically fall into one of the two categories—resident flora and transient flora.

Resident Flora

These organisms are life-long members of the body's normal microbial community.

- They are very closely associated with a particular area. When disturbed, they again re-establish themselves. For example, *Escherichia coli* is a resident flora of the intestine.
- They do not cause harm; rather they have beneficiary effect on the host (described later).

Transient Flora

The transient flora consists of microorganisms that inhabit the body surface or mucous membrane temporarily for a short interval.

- Many of the transient flora are potential pathogens which may cause disease under certain conditions, e.g. pneumococcus and meningococcus in nasopharynx.
- In hospitals, patients may acquire many resistant organisms as transient flora from the healthcare workers and hospital environment. For examples, MRSA (Methicilin-resistant *Staphylococcus aureus*) in nose and skin, multidrug resistant gram-negative organisms such as *Klebsiella, Escherichia coli, Pseudomonas, Acinetobacter* in respiratory tract.
- In contrast to resident flora, they can be easily eliminated from the body surface by following proper hand hygiene and other infection control practices.

MICROBIOLOGY OF NORMAL FLORA

The resident microbial flora is more or less constant for a given area of the body at a given age.

- Humans acquire the normal flora soon after the birth and then continue to harbor until death.
- Although life is possible without normal flora (e.g. germ free experimental animals), but they certainly have a definite role in maintaining health and normal functions of their host.
- The presence of the normal microbial flora in a given body site depends upon various local factors:
  - Local temperature, moisture, pH (acidic or alkaline)
  - Presence of certain nutrients and inhibitory substances
  - Environmental flora (hospital or community)
  - Immune status of the individual
  - Anatomical site: Skin or mucosa (gastrointestinal, respiratory or urogenital)
- Most of the normal flora predominantly contain bacteria and to a less extent some fungi. The existence of viruses and parasites as normal flora is doubtful.
- The total population of normal flora in humans is roughly about 10^{14} bacteria; which is more than total number of cells (10^{13}), present in human body.
- Overall, anaerobic flora dominates over aerobes; the ratio of anaerobic/aerobic bacteria varies depending upon the body site (Table 53.1).
- GIT is the predominant site, where over 400 species of different bacteria have been counted till date.

TABLE 53.1: Microbiology of normal flora

Anatomical Site	Total bacteria/ gm or mL	Anaerobic/ Aerobic Ratio	Anaerobic Normal flora (common)	Aerobic Normal flora	
Mouth				**Predominant**	**Less predominant**
Saliva	10^8–10^9	1:1	▪ Anaerobic cocci ▪ *Actinomyces* ▪ *Fusobacterium* ▪ *Bifidobacterium* ▪ *Prevotella* ▪ Spirochetes	Viridans streptococci	
Tooth surface	10^{10}–10^{11}	1:1			
Gingiva	10^{11}–10^{12}	10^3:1			
Nasopharynx				**Predominant**	**Less predominant**
			▪ *Prevotella* species ▪ Anaerobic cocci ▪ *Fusobacterium*	▪ Streptococci (α and non-hemolytic) ▪ *Neisseria* (non-pathogenic species) ▪ Diphtheroids ▪ *Staphylococcus epidermidis*	▪ *Haemophilus* ▪ Meningococcus ▪ Pneumococcus ▪ *Staphylococcus aureus* ▪ Gram-negative rods ▪ Yeasts
Gastrointestinal tract				**Predominant**	**Less predominant**
Stomach	0–10^5	1:1	*Lactobacillus*	*Helicobacter pylori*	
Jejunum/ileum	10^4–10^7	1:1	▪ Anaerobic cocci ▪ *Bacteroides fragilis*	▪ Enterobacteriaceae and other gram-negative rods ▪ Enterococci ▪ Streptococci (α and non hemolytic), *S. agalactiae*	▪ Diphtheroids ▪ *Candida albicans* and other yeasts ▪ *Staphylococcus aureus*
Terminal ileum and colon	10^{11}–10^{12}	10^3:1	▪ *Fusobacterium* ▪ *Bifidobacterium* ▪ *Prevotella* ▪ *Clostridium*		
Female genital tract				**Predominant**	**Less predominant**
Vagina	10^7–10^9	10:1	▪ Anaerobic cocci ▪ *Lactobacillus* ▪ *Prevotella* ▪ *Bifidobacterium* ▪ *Clostridium*	▪ *Corynebacterium* species ▪ *Lactobacillus* species ▪ Streptococci *(α,* non hemolytic and *S.agalactiae)* ▪ *Neisseria* (non-pathogenic species)	▪ Enterococci ▪ Enterobacteriaceae and other Gram-negative rods ▪ *S. epidermidis* ▪ *Candida albicans* and other yeasts
Skin				**Predominant**	**Less predominant**
	10^2–10^3	3:2	▪ *Propionibacterium* ▪ Anaerobic cocci	▪ *Staphylococcus epidermidis* ▪ Diphtheroids ▪ *Micrococcus* species ▪ *Neisseria* (Non-pathogenic species) ▪ Streptococci (α and non hemolytic)	▪ *Staphylococcus aureus* ▪ *Candida* species ▪ *Acinetobacter* species

- The most common normal flora in humans is *Bacteroides fragilis*; however among aerobes, it is *Escherichia coli*; both are a part of intestinal flora.

The microbiological profile of the normal flora in various sites of human body is given in Table 53.1.

ROLE OF NORMAL FLORA

Various microorganisms present in the normal flora have different relationship with the host.

- They may have beneficiary effect on the host or;
- They may be harmful to the host (if enter into a wrong site causing endogenous infection), or;
- They may exist as commensals (inhabiting the host for long periods without causing detectable harm or benefit).

Beneficial Effects

The normal microbial flora has several beneficial effects to the host (Fig. 53.1) which is proved experimentally by comparing between the conventional animals having normal flora with germ-free animals (animals lacking normal flora) and gnotobiotic animals (animals harboring certain few known microorganisms). The beneficial effects of normal flora are as follows:

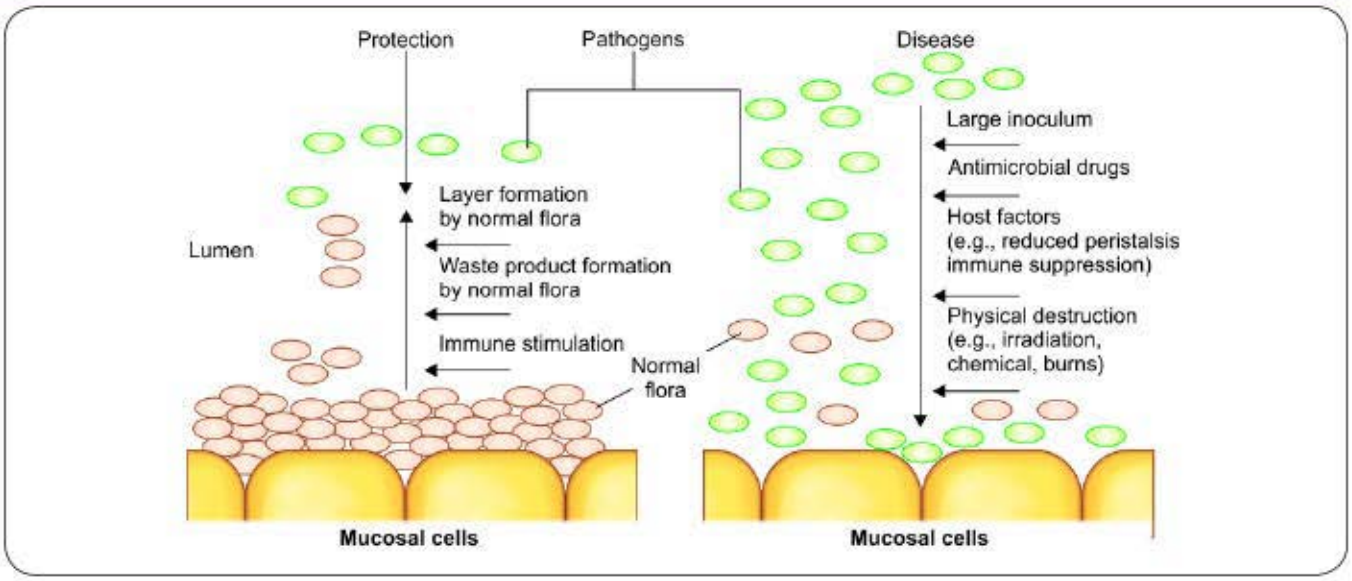

Fig. 53.1: Beneficial effect of normal flora in health and disease

- **Prevent colonization of pathogen:** The normal flora prevent colonization of pathogens by competing for attachment sites or for essential nutrients.
- **Synthesize vitamin:** Human enteric bacteria secrete several vitamins such as Vitamin K and B complex (e.g. Vitamin B12) in excess; which can be absorbed by the host as nutrient.
- **Waste produced antagonize other bacteria:** Normal flora may inhibit or kill other nonindigenous organisms by producing a variety of waste substances such as:
  - Fatty acids and peroxides
  - Lactic acid: Lactobacilli present as normal flora in vagina of adult females maintain the acidic pH by producing lactic acid, thereby prevent the growth of pathogenic bacteria.
  - Bacteriocin: Some bacterial flora may produce bacteriocin or colicins which are antibiotic-like substances that can inhibit or kill other bacteria.
- **Immune stimulation:** Normal microbial flora being foreign to the host stimulates the host's immune system.
  - **Development of lymphatic tissues:** Immune stimulation helps in development of lymphatic tissues in the local sites (e.g. Peyer's patches in intestine).
  - **Stimulate antibody production:** The antigens of the normal microbial flora stimulate the host immune system to produce antibodies that cross-react with pathogens having related or shared antigens and prevent their entry.
- **Prevent allergic diseases (Hygiene hypothesis):** It states that a lack of early childhood exposure to symbiotic microorganisms (e.g. gut flora or probiotics), infectious agents and parasites increases susceptibility of the individual to allergic diseases by suppressing the natural development of the immune system.
- **Complement activation:** The endotoxins liberated by the Gram-negative population of normal flora may help the defense mechanisms of the body by triggering the alternative complement pathway.

Disturbed Normal Flora Promote Infection

When the composition of normal flora is disturbed, it facilitates pathogenic organisms to enter and cause disease. Several mechanisms by which the normal flora is disturbed are as follows:

- **Injudicious use of broad spectrum antimicrobial agent**—It may completely suppress the normal flora thus permitting the pathogen (exogenous and endogenous) to take the upper hand and cause infection. *Clostridium difficile*, an obligate anaerobe which is found in minute quantity as endogenous flora, may flourish when the normal flora is suppressed due to administration of broad spectrum antibiotics especially clindamycin. It liberates toxins resulting in serious life-threatening illness called pseudomembranous colitis.
- **Host factors** such as immune suppression, reduced peristalsis may promote the pathogen to grow.
- **Physical destruction** of the normal flora—by irradiations, chemicals, burns, etc.
- If the **inoculum size** of the entering pathogen is high then it can dominate over the normal flora.
- **Minor trauma** in mouth (e.g. by dental procedure, chewing or vigorous brushing) can promote passage of small numbers of bacteria (e.g. viridians streptococci) transiently into bloodstream, which can cause bacterial endocarditis.

TABLE 53.2: Diseases produced by normal flora

Diseases produced by normal flora	Anatomical site from which the flora is transferred
Urogenital infections including UTI	Intestinal flora such as *Escherichia coli, Klebsiella, Proteus*
Endocarditis	Oral flora (Viridans streptococci)
Dental caries and periodontal disease	Oral flora (*Streptococcus mutans*)
Peritonitis, abdominal infection	Intestinal flora
Pneumonia	Transient respiratory flora
Septicemia	From any site

Harmful Effects

Normal flora may produce the following harmful effects, out of which the first two are significant.

- **May be agents of disease:** Members of the normal flora may cause endogenous disease (Table 53.2).
  - When the host immunity is lowered, the transient flora may invade and produce disease, e.g. Gram-negative organisms (*E. coli*) colonizing the respiratory tract can cause pneumonia.
  - If they enter a wrong site or tissue (e.g. blood, sterile body cavities)—then even the resident flora can produce disease. For example *E. coli* which is a resident flora of intestine may cause urinary tract infection if enters into urinary tract.
- **Transfer to susceptible hosts:** Some pathogens of humans that are members of the normal flora for one host can produce disease if transferred to the other host. For example, the pathogens that colonize the upper respiratory tract (such as meningococcus, pneumococcus, etc) can produce disease in susceptible hosts.
- **Bacterial synergism:** Bacterial vitamins and growth factors produced by members of the normal flora may promote the growth of the potential pathogens.
- **Contribute to the drug resistance of pathogens:** Some members of normal flora produce enzymes such as beta lactamases which destroy the beta lactam antibiotics; thus indirectly contribute to the drug resistance of pathogens that are otherwise susceptible to the drug.
- **Competition for host nutrients:** Bacteria in GIT absorb some of the host's nutrients for their survival. Germ-free animals are known to grow more rapidly and efficiently than conventional animals.

Probiotics

The term "Probiotics" is defined as the live microorganisms (part of normal flora) which, when administered in adequate amounts, confer a health benefit to the host.

- They are extremely useful in the conditions where the normal intestinal flora is suppressed.
- Probiotics are commercially available in the form of capsule or sachet, consisting of mixture of some important beneficiary bacteria and yeast of human intestinal flora such as *Bacillus coagulans, Bifidobacterium longum, Lactobacillus acidophilus, Saccharomyces boulardii,* etc.

Probiotics are found to have beneficiary role in the following conditions/diseases:

- To treat various forms of GIT conditions like:
  - Gastroenteritis due to any cause
  - Antibiotic-associated diarrhea
  - Lactose intolerance
  - Irritable bowel syndrome and colitis
  - Necrotizing enterocolitis
  - *Helicobacter pylori* infection
- Reducing serum cholesterol level by breaking down bile in the gut, thus inhibiting its reabsorption.
- Reducing blood pressure (by producing ACE inhibitor-like peptides during fermentation).
- Immune function restoration and preventing infections
- Modulate inflammatory and hypersensitivity responses, hence can be given in allergic disorders, eczema and atopic dermatitis.
- Bacterial vaginosis (restoring the acid pH of vagina by lactic acid producing bacteria)

The live organisms contained in probiotics must remain live to have their action on the large intestine. More so, they have to compete with the existing flora to get themselves established. They can exert their beneficiary effect only after that. Hence, now a days, instead of probiotics, another related preparation called prebiotics is being increasingly used.

Prebiotics

In contrast to probiotics, prebiotics are the dietary non digestible fibers which when administered, stimulate the growth and activity of commensal microorganisms and thereby exert beneficiary effect to the host indirectly.

EXPECTED QUESTIONS

I. Write short notes on:

1. Resident flora and transient flora
2. Harmful effects of the normal flora
3. Beneficial effects of the normal flora
4. Probiotics

CHAPTER 54

Clinical Microbiology (Infective Syndromes)

Chapter Preview

- Urinary tract infections
- Diarrheal diseases
- Meningitis
- Blood stream infections
- Fever of unknown origin
- Respiratory tract infections
- Skin, soft tissue and wound infections
- Sexually transmitted infections
- Congenital infections
- Eye infections
- Ear infections

URINARY TRACT INFECTION

Urinary tract infection (UTI) is defined as a disease caused by microbial invasion of the urinary tract that extends from the renal cortex of the kidney to the urethral meatus.

- The presence of detectable bacteria in urine is named as bacteriuria.
- Presence of pus cells in urine is referred to as pyuria.

Classification

- UTIs may be broadly classified into two types—lower UTI and upper UTI (Table 54.1) depending upon the anatomical sites involved.
- Depending upon the source of infection, UTI can be of two types—hospital acquired and community acquired.

Epidemiology

Urinary tract infections (UTIs) are among the most common bacterial infections that need medical care; accounting for second most common infection after respiratory tract infections in the community. Whereas in hospitals, they are the most common HAIs (hospital acquired infections) accounting for 35% of total HAIs.

TABLE 54.1: Comparison between lower and upper UTIs

	Lower UTI	Upper UTI
Sites involved	Urethra, and bladder	Kidney and ureter
Symptoms	Local manifestations-dysuria, urgency, frequency	Local & systemic manifestations (fever, vomiting, abdominal pain)
Route of spread	Ascending route	Both ascending (common) and descending route
Occurrence	More common	Less common

Predisposing Factors

- **Prevalence:** About 10% of humans develop UTI in some part of their life.
- **Gender:** UTI is predominantly a disease of females. The higher prevalence in females is due to the anatomical structure of female urogenital system, (1) short urethra, and (2) close proximity of urethral meatus to anus; so that there is more chance of introduction of endogenous bacteria into the urinary tract.
- **Age:** Incidence increases with age.
  - During first year of life, the prevalence is around 2% in both females and males.
  - After that, the incidence of UTI decreases in males until old age where they again show an increased prevalence because of the prostate enlargement which interferes with emptying of the bladder.
  - Whereas in females, the incidence keeps increasing after first year of life.
    - During 5–17 years, the incidence of bacteriuria is about 1–3%.
    - Thereafter in adult life, the incidence is around 10–20%.
    - Reinfection is common in females (20–40 years of age), as many as 50% would suffer a reinfection within one year.
- **Pregnancy:** Anatomical and hormonal changes in pregnancy favor development of UTIs. Most females develop asymptomatic bacteriuria during pregnancy. In some, it can lead to serious infections in both mother and fetus.
- **Structural and functional abnormality** of urinary tract may cause obstruction to the urine flow and urinary stasis; which predisposes to infection.

- Structural obstruction: E.g. urethral stricture, renal and ureteric stones, prostate enlargement, tumors, renal transplants, etc.
- Functional obstruction: E.g, neurogenic bladder due to spinal cord injury or multiple sclerosis.

- **Bacterial virulence** such as expression of pili helps in bacterial adhesion to uroepithelium.
- **Vesico-ureteric reflux:** If the normal valve-like mechanism at the vesico-ureteric junction is weakened, it allows urine from bladder up into ureters and sometimes into the renal pelvis.
- **Genetic factors:** Genetically determined receptors present on uroepithelial cells may help in bacterial attachment.

UTI is the leading cause of gram-negative sepsis especially in hospitalized patients and the urinary catheters are the origin of nearly 50% of nosocomial UTIs.

TABLE 54.2: Common microorganisms causing UTIs

Bacterial agents:	Other agents:
Gram-negative Bacilli: ▪ ***Escherichia coli:*** Most common ▪ *Klebsiella pneumoniae* ▪ *Proteus mirabilis* ▪ *Pseudomonas aeruginosa* ▪ *Acinetobacter* species ▪ *Enterobacter* species ▪ *Serratia* species	**Fungus:** *Candida albicans* **Parasites:** ▪ *Schistosoma hematobium* ▪ *Trichomonas vaginalis*
Gram-positive Cocci: ▪ *Staphylococcus saprophyticus* ▪ *Staphylococcus aureus* ▪ *Staphylococcus epidermidis* ▪ *Enterococcus* species	**Viruses:** ▪ Herpes simplex virus ▪ Adenovirus ▪ JC and BK virus ▪ Cytomegalovirus

Abbreviations: UTI, Urinary tract infection; JC, John Cunningham

Etiology

Escherichia coli (uropathogenic *E.coli*) is by far the most common cause of all forms of UTIs (i.e. community acquired & nosocomial UTI and upper & lower UTI) accounting for 70% of total cases.

- The endogenous flora such as gram-negative bacilli (e.g. *E.coli, Klebsiella, Proteus,* etc) and enterococci are the important agents.
- In hospital acquired UTIs, the agents are often multidrug resistant. In addition to the members of Enterobacteriaceae, other organisms such as staphylococci, *Pseudomonas, Acinetobacter* are also increasingly reported.
- In general, viruses and parasites are not considered as urinary pathogens except for few (Table 54.2). Among fungi, *Candida albicans* is a frequent cause of UTI.

Pathogenesis

Bacteria invade the urinary tract mainly by two routes—ascending and descending routes (Fig. 54.1).

Ascending Route

It is the most common route; the enteric endogenous bacteria (*E.coli*, other gram-negative bacilli, enterococci) enter the urinary tract which is facilitated by sexual intercourse, or instrumentation (e.g. catheterization), etc.

- **Colonization:** Adhesion to urethral epithelium is the first and the most important step in pathogenesis. A number of virulence factors (e.g. P fimbria, mannose resistant fimbria in *E.coli*) help in adhesion.
- **Ascension:** Following colonization, pathogen ascends through urethra upwards towards bladder to cause cystitis. Bacterial toxins may facilitate ascension by inhibiting peristalsis (urinary stasis).
- **Further ascension** through ureter may occasionally occur if there is vesico-ureteric reflux leading to pyelonephritis (infection of renal parenchyma causing an acute inflammatory response).
- **Acute tubular injury:** If the inflammatory cascade continues, tubular obstruction and damage occurs which may lead to interstitial nephritis.

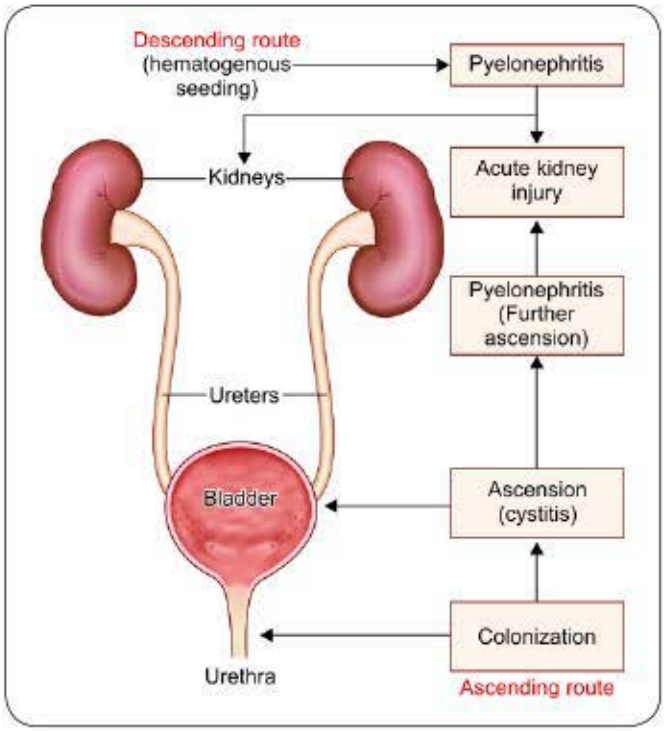

Fig. 54.1: Pathogenesis of urinary tract infection

TABLE 54.3: Host defense mechanisms against UTIs

Urine factors	Mucosal immunity
Acidic urine- inhibit pathogens	Uroepithelial secretion of cytokines (induced by bacterial LPS)
High urine osmolality- inhibit pathogens	Mucosal IgA- prevent attachment of pathogen to uroepithelium
Urinary inhibition of bacterial adherence	Tamm Horsfall protein (uromucoid)—a glycoprotein secreted by epithelial cells of kidney, serves as anti-adherence factor by binding to type-I fimbria of *Ecoli*
Mechanical flushing of urine flow	In men: (1) Zinc in prostatic secretions is bactericidal, (2) long urethra

Abbreviation: LPS, Lipopolysaccharide

Descending Route

This refers to invasion of renal parenchyma through hematogenous seedling of the pathogen, which occurs as a consequence of bacteremia. This accounts for 5% of total UTIs. Although most infections affecting kidney are acquired by ascending route, certain organisms are particularly invasive and their association with pyelonephritis often indicates a descending route of origin; for example—*Staphylococcus aureus, Salmonella, Mycobacterium tuberculosis, Leptospira* and *Candida*.

Host Defense Mechanisms

Host defense mechanisms play an important role in prevention of UTI. They can be grouped into—(1) factors related to urine, (2) activation of host's mucosal immunity by the uropathogens (Table 54.3).

Clinical Manifestations

UTIs may be presented in various forms:

1. Asymptomatic bacteriuria
2. Lower UTI: Cystitis, and acute urethral syndrome
3. Upper UTI (pyelonephritis)

Cystitis (Infection of Bladder)

It is characterized by localized symptoms such as:

- Dysuria (pain while micturition), frequency, urgency, and supra-pubic tenderness (over the bladder area).
- Urine becomes cloudy, with bad odor, and in some cases grossly bloody (hematuria).
- There is not associated systemic manifestation.

Asymptomatic Bacteriuria

It refers to isolation of specified quantitative count of bacteria in an appropriately collected urine specimen, obtained from a person without symptoms of UTI. It is more common in females and its incidence increases with age (1% among school girls to more than 20% in old age).

Clinical Significance

- Asymptomatic UTI is clinically significant in certain group of people such as pregnant women (as chances of complication in mother and fetus are more), people undergoing prostatic surgery or any urologic procedure where bleeding is anticipated. Therefore, in this group the routine screening and treatment for asymptomatic UTI is highly recommended.
- In contrast, asymptomatic UTI is not clinically significant in non-pregnant, pre-menopausal women, old age, catheterized patient, or patients with spinal injury. In such cases, neither screening for or treatment of asymptomatic UTI is needed.

Acute Urethral Syndrome

This is another form of lower UTI seen in young sexually active females, characterized by:

- Presence of classical symptoms of lower UTI as described for cystitis
- Bacterial count is often low (10^2 to 10^5 CFU/mL)
- Pyuria is present
- **Agents:** Most are due to usual agents of UTI, few cases may be caused by gonococcus, *Chlamydia*, herpes simplex virus, etc.

Upper UTI or Pyelonephritis

Pyelonephritis refers to inflammation of kidney parenchyma, calyces and the renal pelvis i.e. the part of ureter present inside the kidney.

- Associated with systemic manifestations such as—fever, flank pain, vomiting.
- Lower tract symptoms such as frequency, urgency and dysuria may also be present.

Laboratory Diagnosis

- **Specimen collection:** Urine should be collected in a wide mouth screw capped sterile container by—(1) midstream urine, (2) suprapubic aspiration from bladder, (3) In catheterized patients—urine aspirated from the catheter tube after clamping distally and disinfecting, but never collected from urine bag.
- **Transport:** Urine sample should be processed immediately. If delay is expected then it can be refrigerated or stored by adding boric acid.
- **Direct examination:** Screening tests done are as follows:
  - Wet mount examination is done to demonstrate the pus cells in urine.
  - Leukocyte esterase test—to detect the esterase enzyme liberated by leukocytes.
  - Nitrate reduction test (Griess test)—to detect nitrate reducing bacteria.
  - Catalase test—to detect catalase producing bacteria
  - Gram-staining of urine.

- **Culture:** Urine sample should be inoculated onto MacConkey agar and blood agar or CLED (cysteine lactose electrolyte deficient) agar.
  - A count of ≥10^5 **colony forming units (CFU)/mL** of urine is considered as significant – indicates infection (referred to as 'significant bacteriuria')
  - **Low count of** ≤ 10^4 CFU/mL is considered as insignificant – indicates presence of commensal bacteria (due to contamination during voiding).
  - **Quantitative culture** such as pour plate method is carried out to count the number of colonies.
- **Antibody coated bacteria test:** It is used to differentiate upper and lower UTI.

The laboratory diagnosis of UTI has been described in detail in chapter 29.

TREATMENT **Urinary tract infections**

Treatment should be based on antimicrobial susceptibility testing report. Quinolones, nitrofurantoin, cephalosporins, and aminoglycosides are among the preferred drugs.

DIARRHEAL DISEASES

Definition

Diarrhea

Diarrhea is defined as passage of three or more loose or liquid stools per day, in excess than the usual habitat for that person (World Health Organization). It may be caused by microbial infections, or as a result of other gastrointestinal diseases such as inflammatory bowel diseases, coeliac disease, etc. Common microbial agents causing diarrhea and the mechanisms involved are summarised in Table 54.4.

Gastroenteritis

Gastroenteritis or infectious diarrhea may be defined as inflammation of the mucous membrane of stomach and intestine resulting in combination of diarrhea, vomiting and pain abdomen with or without mucus/blood/fever/dehydration.

TABLE 54.4: Infectious agents of acute diarrhea and the underlying mechanism

Mechanism	Features	Examples of pathogens involved	
Non-inflammatory	**Location:** Proximal small bowel **Illness:** Watery diarrhea **Stool findings:** ▪ No fecal leukocytes ▪ Fecal lactoferrin—not increased	**Bacteria:** **(Mostly Enterotoxin mediated)** ▪ *Vibrio cholerae* ▪ *Escherichia coli* • Enteropathogenic • Enterotoxigenic • Enteroaggregative ▪ *Clostridium perfringens* ▪ *Bacillus cereus* ▪ *Staphylococcus aureus* ▪ *Aeromonas hydrophila* ▪ *Plesiomonas shigelloides*	**Viruses:** ▪ Rotavirus ▪ Norovirus ▪ Enteric adenoviruses **Parasites:** ▪ *Giardia lamblia* ▪ *Cryptosporidium* species ▪ *Cyclospora* species ▪ Microsporidia
Inflammatory (invasion or cytotoxin)	**Location:** Colon or distal small bowel **Illness:** ▪ Dysentery or ▪ Inflammatory diarrhea **Stool findings:** ▪ Fecal pus cells (polymorphonuclear leukocytes)—increased ▪ Fecal lactoferrin—increased	**Predominantly dysentery:** ▪ *Shigella* species ▪ *Campylobacter jejuni* ▪ Enterohemorrhagic *E. coli* ▪ Enteroinvasive *E. coli* ▪ *Vibrio parahaemolyticus* **Predominantly inflammatory diarrhea** ▪ *Salmonella* species ▪ *Yersinia enterocolitica* ▪ *Listeria monocytogenes* ▪ *Clostridium difficile* ▪ *Aeromonas hydrophila* ▪ *Plesiomonas shigelloides* ▪ *Klebsiella oxytoca*	**Parasite** (predominantly dysentery) ▪ *Entamoeba histolytica,* ▪ *Balantidium coli*
Penetrating	**Location:** Distal small bowel **Illness:** Enteric fever **Stool findings:** Fecal mononuclear leukocytes (↑)	*Salmonella* Typhi, (enteric fever) *Yersinia enterocolitica* (typhoid like features)	

TABLE 54.5: Infectious agents of food poisoning

Incubation period, Organism	Symptoms	Common food sources
1–6 h		
Staphylococcus aureus	Nausea, vomiting, diarrhea	Ham, poultry, potato or egg salad, mayonnaise, pastries
Bacillus cereus	Nausea, vomiting, diarrhea	Fried rice
Clostridium botulinum	Nausea, vomiting, diarrhea	Canned food
8–16 h		
Clostridium perfringens	Abdominal cramps, diarrhea (vomiting rare)	Beef, poultry, legumes, gravies
B. cereus	Abdominal cramps, diarrhea (vomiting rare)	Meats, vegetables, dried beans, cereals
>16 h		
Vibrio cholerae	Watery diarrhea	Shellfish, water
Enterotoxigenic *E. coli*	Watery diarrhea	Salads, cheese, meat, water
Enterohemorrhagic *E. coli*	Bloody diarrhea	Ground beef, salami, raw milk, raw vegetables, apple juice
Salmonella species	Inflammatory diarrhea	Beef, poultry, eggs, dairy products
Campylobacter jejuni	Inflammatory diarrhea	Poultry, raw milk
Shigella species	Dysentery	Potato or egg salad, lettuce, raw vegetables
Vibrio parahaemolyticus	Dysentery	Mollusks, crustaceans

Dysentery

Dysentery is characterized by diarrhea with increased blood and mucus, often associated with fever, abdominal pain, and tenesmus (a feeling of incomplete defecation).

Food Poisoning

Food poisoning refers to an illness acquired through consumption of food or drink contaminated either with microorganisms, or their toxins.

- There are several non-bacterial agents that can cause food poisoning such as capsaicin (found in hot peppers), variety of toxins found in fish and shellfish, poisonous mushrooms and some chemical poisons.
- The microbial causes of food poisoning have been listed in table 54.5.

Traveler's Diarrhea

Traveler's diarrhea is the most common travel-related infectious illness.

- Occurs in about 20–50% of people travelling from temperate industrialized countries to tropical regions of Asia, Africa, and Central and South America;
- Characterized by a sudden onset of abdominal cramps, anorexia, and watery diarrhea.
- Microbial agents causing traveler's diarrhea are listed in table 54.6.

Epidemiology

Worldwide, about 1.7 to 5 billion cases of diarrhea occur per year, with 1.26 million deaths; accounting for the second leading cause of death globally. It is more common in developing countries, where young children get diarrhea on an average three times a year.

TABLE 54.6: Agents causing traveler's diarrhea

Etiologic agent	Comments
Bacteria (50–75%)	
Enterotoxigenic *E. coli* (10–45%)	Single most important agent
Enteroaggregative *E. coli* (5–35%)	Emerging enteric pathogen with worldwide distribution
Campylobacter jejuni (5–25%)	More common in Asia
Shigella	Major cause of dysentery
Salmonella	Common agent in India
Others	Including *Aeromonas, Plesiomonas*, and *Vibrio cholerae*
Viruses (<20 %)	
Norovirus (<10%)	Associated with cruise ships
Rotavirus (<5%)	Common among children
Parasites (0–10 %)	*Giardia lamblia, Cryptosporidium, Entamoeba histolytica, Cyclospora*

Etiological Agents

The microbial agents of diarrheal diseases (gastroenteritis), dysentery and food poisoning are summarized in tables 54.4, 54.5 and 54.6 respectively.

Pathogenic Mechanisms

Enteric pathogens have developed a variety of strategies to overcome host defences (Table 54.7).

TABLE 54.7: Pathogenic mechanisms of diarrheal agents

Toxins production		
Enterotoxins	**Cytotoxins**	**Neurotoxins**
Cholera toxin *Vibrio parahaemolyticus* *E. coli* ▪ LT and ST of ETEC ▪ EAST of EAEC ▪ VT of EHEC *Clostridium difficile* (toxin A) *Aeromonas* *Rotavirus (NSP4)* *Campylobacter jejuni*	*Shigella dysenteriae* type 1 Enterohemorrhagic *E.coli* *Clostridium difficile* (toxin B)	*Staphylococcus aureus* enterotoxin *Bacillus cereus* toxin *Clostridium botulinum* toxin
Attachment within or close to mucosal cells	**Invasion of intestinal epithelium**	
E. coli ▪ Enteropathogenic ▪ Enterohemorrhagic *Cryptosporidium* species *Cyclospora* species Rotavirus Norovirus	*Shigella* species Enteroinvasive *E. coli* *Campylobacter jejuni* *Yersinia enterocolitica* *Plesiomonas shigelloides* *Entamoeba histolytica* *Balantidium coli*	

Abbreviations: LT, heat labile toxin; ST, heat stable toxin; ETEC, Enterotoxigenic *E. coli*; EAST, Enteroaggregative *E. coli* heat-stable enterotoxin; EAEC,Enteroaggregative *E. coli*; VT, verocytotoxin; EHEC, Enterohaemorrhagic *E. coli*; NSP4; non-structural protein-4

Inoculum Size

Enteric pathogens differ from each other in their infective dose (minimum dose required to initiate infection) as follows:

- *Shigella*, enterohemorrhagic *E.coli*, *Giardia*, or *Entamoeba*: 10–100 bacteria or cysts
- *Vibrio cholerae:* 10^5–10^8 bacilli
- *Salmonella*: 10^3–10^5 bacilli

Adherence

Adherence to intestinal mucosa helps the organism to compete with the normal bowel flora and there by colonizing the intestinal mucosa. This is crucial for the pathogenesis of many diarrheal agents such as Enteropathogenic *E. coli*, enterohemorrhagic *E. coli*, enterotoxigenic *E. coli* and *V. cholerae*.

Toxin Production

Enteric organisms can produce variety of toxins, which are implicated in pathogenesis (Table 54.7). These include:

- **Enterotoxins:** Cause watery diarrhea by acting directly on secretory mechanisms in the intestinal mucosa.
- **Cytotoxins:** Cause destruction of mucosal cells, leading to inflammatory diarrhea.
- **Neurotoxins:** Act directly on the central nervous system producing vomiting.

Invasion

In addition to producing cytotoxins, bacterial invasion is another mechanism by which destruction of intestinal mucosal cells takes place resulting in dysentery (Table 54.7).

Host Factors

Alterations of the host defense mechanisms can promote the diarrheal diseases.

- Suppression of the normal flora
- Neutralization of gastric acidity: Promote the acid labile pathogens (e.g. *V.cholerae*)
- Inhibition of intestinal motility: Interfere with the clearance of bacteria from small intestine
- Impaired host immunity
- Genetic Determinants: Host genetic variation influences susceptibility to diarrheal diseases. People with blood group O show increased susceptibility to disease due *to V. cholerae, Shigella, E. coli* O157, and Norovirus.

Laboratory Diagnosis

Specimen Collection

- Fecal specimen (containing mucus flakes) is collected in a sterile screw capped wide mouthed container. In carriers, a rectal swab may be collected.
- In food poisoning outbreaks, vomitus, stool or the suspected food materials are the ideal specimens. The food material should be homogenized or washed thoroughly in sterile diluent, e.g. Ringer's solution.

Microscopy

- **Wet mount preparation** in saline or iodine is done for detection of pus cells, RBCs and detection of parasitic cysts, trophozoites, eggs or larvae.
- **Hanging drop preparation:** It is done for liquid specimens to demonstrate darting motility of *Vibrio cholerae*; which can be further confirmed by inhibition of motility by adding H–antisera.
- **Gram stained smear:** Gram-staining is not routinely done because of presence of normal flora in feces. It is recommended only in special situations where the typical morphology would suggest preliminary clue for diagnosis:
  - Presence of comma shaped bacilli: *Vibrio cholerae*
  - Budding oval yeast cells in immunocompromised host or infant—suggestive of *Candida* species.

- **Acid fast staining** can be carried out for detection of oocysts of *Cryptosporidium, Isospora* and *Cyclospora*.
- **Electron microscopy** for detection of morphology of specific viruses causing gastroenteritis.
  - Rotaviruses appear as spokes grouped around the hub of a wheel
  - Astroviruses have star-like morphology
  - Coronaviruses have cup-like depressions on the capsid surface.

Bacterial Culture

- Fecal specimen should be inoculated onto the following media.
  - Enrichment broth: Selenite F broth and alkaline peptone water
  - Mildly selective medium: MacConkey agar
  - Highly selective medium such as: DCA (deoxycholate citrate agar), XLD (xylose lysine deoxycholate) agar and TCBS (thiosulfate citrate bile salt sucrose) agar.
- **Identification:** Appropriate biochemical tests are carried out for identification of the enteric pathogen. Then serotyping is performed with specific group or type specific antisera.
- **Antimicrobial susceptibility test:** It is done to choose appropriate drug.

Tissue Culture

This is carried out for detection of enteric viruses and also for some diarrheogenic *E. coli*. Enterotoxigenic *Escherichia coli* (ETEC) penetrates HeLa and HEp-2 cell line whereas verocytotoxin of enterohemorrhagic *Escherichia coli* (EHEC) is detected by its cytotoxic effect on Vero cell line.

Antigen Detection

ELISA and rapid tests (e.g. latex agglutination) based antigen detection methods are available e.g. detection of antigens of rotavirus, *Entamoeba histolytica, Giardia* and *Cryptosporidium* in stool.

Molecular Methods

Polymerase chain reaction (PCR) assays can be carried out for detection specific genes of enteric pathogens

Toxin Detection

- ELISA based formats are available for detection of enterotoxins in stool.
- PCR for detecting of genes coding for enterotoxins.

Steps of microbiological analysis of stool or food specimens to detect the pathogen responsible for gastrointestinal infection are given in Figure 54.2.

MENINGITIS

Definition

Meningitis is an inflammation of the meninges surrounding the brain and spinal cord. In true sense, it implies to infection of subarachnoid space or the leptomeninges (arachnoid and piamater) but not duramater.

Types of Meningitis and their Causative Agents

Based on the changes in leukocytes in cerebrospinal fluid (CSF), meningitis can be grouped into:

- **Pyogenic meningitis:** It is characterized by elevated polymorphonuclear cells in CSF.
  - It is exclusively caused by bacterial agents.
  - According to the age, the agents involved may vary (Table 54.8).
  - Overall *Streptococcus pneumoniae* is the most common cause of pyogenic meningitis.
  - However for the neonatal meningitis, the common agents are Group B *Streptococcus, Escherichia coli,* and *Listeria*.
- **Aseptic meningitis:** It is characterized by elevated lymphocytes in CSF. The etiological agents include viral, tubercular, fungal and parasitic agents (Table 54.9). The term 'aseptic' is frequently a misnomer, implying a lack of infection. On the contrary, with the advent of PCR and other newer diagnostic methods, it is now possible to detect most of these agents.

Pathogenesis

Routes of Infection

Organisms may gain access to the meninges by several routes:

- **Hematogenous spread:** This is the most common route, where entry into the subarachnoid space is gained through the choroid plexus or through other blood vessels of the brain.
- **Direct spread from an infected site** present close to meninges—otitis media, mastoiditis, sinusitis, etc.
- **Anatomical defect in central nervous system (CNS):** It may occur as a result of surgery, trauma, congenital defects which can allow organisms for ready and easy access to CNS.
- **Direct intraneural spread along the nerve:** This is the least common route, occurs in cases of rabies virus or herpes simplex virus infection.

Predisposing Factors

Pathogenesis of meningitis depends upon various host and microbial factors.

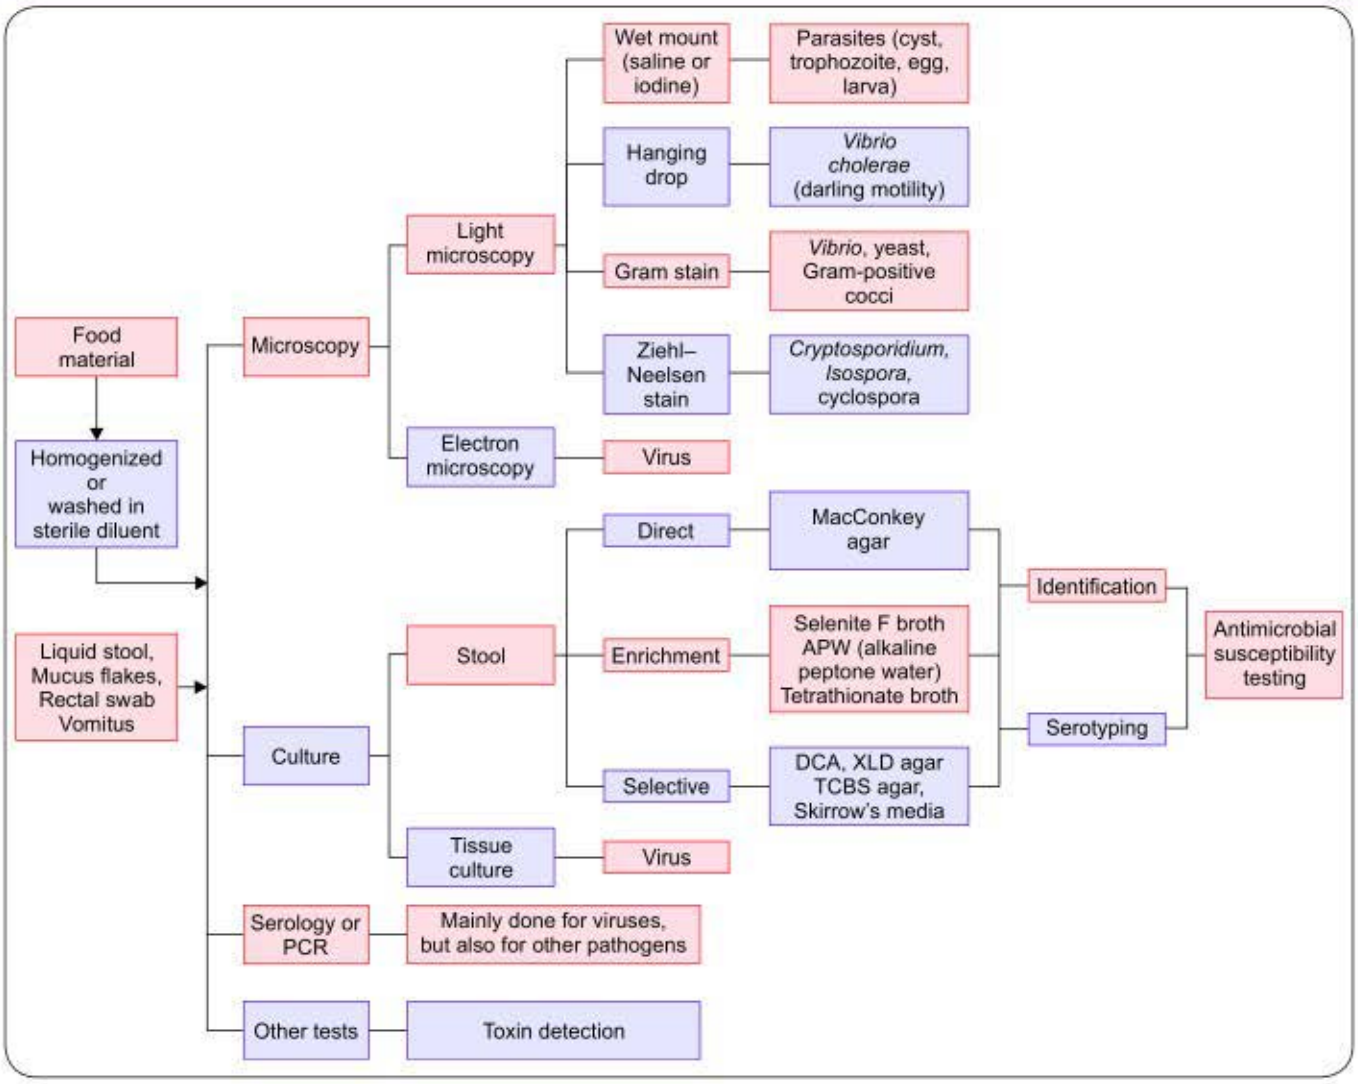

Fig. 54.2: Microbiological analysis of stool/food specimen to detect gastrointestinal pathogen(s)

Abbreviations: PCR, polymerase chain reaction; DCA, deoxycholate citrate agar; XLD, xylose lysine deoxycholate; TCBS, thiosulfate citrate bile salt sucrose

TABLE 54.8: Causes of pyogenic meningitis

Age	Common causes
Neonates or Infants of 0–2 months	▪ *Escherichia coli* ▪ Group B *Streptococcus* (*S. agalactiae*) ▪ Other gram-negative *bacilli* (like *Klebsiella pneumoniae*) ▪ *Listeria monocytogenes*
2–20 years	▪ *Neisseria meningitidis:* Most common ▪ *Haemophilus influenzae* ▪ *Streptococcus pneumoniae*
> 20 years (adults)	▪ *Streptococcus pneumoniae:* Most common agent ▪ *Haemophilus influenzae** ▪ *Neisseria meningitidis*
Overall	Most common agent is: *Streptococcus pneumoniae*

*Incidence of *H. influenzae* meningitis has been dramatically reduced after the start of Hib vaccination

TABLE 54.9: Causes of aseptic meningitis

Viruses	**Enteroviruses** (Polioviruses, echoviruses, Coxsackie viruses): the most common agents Herpes simplex virus 1 and 2 Other Herpes group: VZV, CMV, EBV Myxoviruses: Influenza A and B, parainfluenza virus, and mumps virus Arboviruses, and adenoviruses Rubella viruses and HIV
Bacteria	*M.tuberculosis, Treponema pallidum*, and *Leptospira*
Parasites	*Naegleria* species, *Acanthamoeba* species and *Toxoplasma gondii*
Fungi	*Cryptococcus neoformans*

Abbreviations: CMV, Cytomegalovirus; EBV, Epstein-Barr virus; HIV, Human immunodeficiency virus ;VZV,Varicella-zoster virus

- **Age:** Neonates have the highest prevalence of meningitis; probably due to, (1) their immature immune system, (2) acquiring the colonized organisms from mother's birth canal (e.g. *Listeria* or Group B *Streptococcus*), (3) ↑ permeability of blood brain barrier.
- **Vaccination:** Widespread vaccination is shown to reduce the incidence of meningitis due to the particular agent, e.g. ↓ incidence of *H. influenzae* meningitis following implementation of Hib vaccination.
- **Factors that promote infection at primary site:** Because respiratory tract is the primary portal of entry for many etiological agents of meningitis, the factors that predispose to respiratory infections can also increase the likelihood of development of meningitis. Such factors include alcoholism, diabetes, immunosuppression, splenectomy, etc.
- **Presence of CSF shunts** can also directly predispose to the pathogen entry.
- **Breach in the blood brain barrier (BBB):** Organism can gain access through BBB by:
  - Loss of capillary integrity by disrupting the tight junctions of BBB.
  - Transport within circulatory phagocytes.
  - Crossing the endothelial cells by transport within the endothelial cell vacuoles.
- **Microbial virulence factors** may also contribute to the pathogenesis such as:
  - Capsular polysaccharide
  - Lipoteichoic acid
  - IgA proteases

Clinical Manifestations

Patients with meningitis develop various manifestations such as:

- Important symptoms:
  - High grade fever, vomiting,
  - Intense headache
  - Photophobia (intolerance to bright light)
- Important signs of meningism (meningeal irritation) such as:
  - Neck rigidity
  - Kernig's sign (Severe stiffness of the hamstrings causes an inability to straighten the leg when the hip is flexed to 90 degrees)
  - Brudzinski's sign: Severe neck stiffness causes the patient's hips and knees to flex when the neck is flexed.

Laboratory Diagnosis

Specimen Collection and Transport

- CSF is the most ideal specimen. Other useful specimens are:
  - Blood (for culture),
  - Serum (for antibody or antigen detection),
  - Urine (for antigen detection)
- **CSF collection:** CSF is obtained by lumbar puncture under strict aseptic conditions. It is collected in three sterile containers, one each for cell count, biochemical analysis and bacteriological examination.
- **CSF transport:** The CSF being the most precious specimen should be examined immediately.
  - If delay is expected, it may be kept in an incubator at 37°C.
  - When bacteriological examination is required, CSF should never be refrigerated as delicate pathogens such as *H. influenzae* may die.
- For virus isolation, it may be kept inside the freezer.

Biochemical Analysis and Cell Count of CSF

Biochemical analysis and cell count of CSF give a preliminary clue about the type of meningitis (Table 54.10). For example:

- In acute pyogenic meningitis, the CSF usually contains more than 1000 leukocytes/µl and predominantly neutrophils (90–95%).

TABLE 54.10: Cytological and biochemical parameters in CSF of normal individuals and in different types of meningitis

Character	Normal individual	Pyogenic meningitis	Tuberculous meningitis	Viral meningitis
CSF pressure (mm of water)	Normal (50–150)	Highly elevated (>180)	Moderately elevated	Slightly elevated/normal
Total leukocyte count (per mm^3)	0-5	100- 10,000	10–500	25–500
Predominant cell type	Lymphocytes	Neutrophils	Lymphocytes	Lymphocytes
Glucose (mg%)	40–70	(<40 mg/dL) (decreased to absent)	20–40 mg/dL (slightly decreased)	Normal
Total proteins (mg%)	15–45	>45 mg/dL (usually >250) (markedly increased)	100–500 mg/dL (moderate to markedly increased)	20–80 mg/dL (normal or slightly elevated)

- The total protein content is elevated and the glucose level is markedly diminished or even absent.
- CSF pressure is highly elevated.

- **In Tuberculosis meningitis:** Cell count is slightly increased which is predominantly lymphocytic.
  - Protein level in CSF is markedly increased; glucose level is slightly decreased.
  - Cobweb coagulum formation occurs when CSF is kept for long time in a tube due to high fibrin content of CSF.
  - CSF pressure is moderately elevated
- **In viral meningitis:** Mild lymphocytosis is noticed in CSF. Protein content may be normal or slightly elevated; however glucose level is normal. CSF pressure is mildly elevated.

Microbiological Examination

CSF Microscopy

- **Gram staining of CSF:** Microscopic examination of Gram stained smear may give a preliminary clue about the etiological agent of pyogenic meningitis based on the morphology of the bacteria (Table 54.11).
  - This helps in early initiation of appropriate antimicrobial agents (empirical therapy).
  - **Heaped smear:** As the bacterial load in CSF may be very low, so several drops of CSF should be placed at the same spot on the slide, each being allowed to air dry before the next is added.
  - **Centrifugation:** Alternatively, CSF can be centrifuged (by cytospin) and the deposit is examined for Gram staining.
- **Ziehl Neelsen staining** of CSF smear should be performed to detect *Mycobacterium tuberculosis*. If negative then PCR should be done to detect *M. tuberculosis* specific genes.
- **India ink preparation** of CSF can be examined microscopically for detection of capsule of *Cryptococcus neoformans*, which appears as clear refractive unstained area surrounding the budding yeast cells.
- **Wet mount preparation** can be examined for detection of trophozoites of parasites such as *Naegleria*.

TABLE 54.11: Morphological clue suggesting bacterial pathogens in CSF causing pyogenic meningitis

Morphology of bacteria	Suggestive of-
Gram positive cocci in pair, lanceolate shaped	*Streptococcus pneumoniae*
Gram positive cocci in short chain (in neonate)	*Streptococcus agalactiae*
Gram negative cocci in pair, intracellular, inside the pus cells	*Neisseria meningitidis*
Pleomorphic gram-negative bacilli	*Haemophilus influenzae*
Gram negative bacilli	*Escherichia coli* or other gram-negative bacilli

Antigen Detection

- **From CSF:** After centrifugation of CSF, the supernatant can be used for antigen detection. Latex agglutination test formats are available for detection of capsular antigens of common agents of meningitis such as:
  - *Cryptococcus neoformans*
  - *Streptococcus pneumoniae*
  - *Streptococcus agalactiae*
  - *Neisseria meningitidis*
  - *Haemophilus influenzae*
- **From urine:** Various test formats are available to detect capsular antigen in urine; *e.g.*
  - *Streptococcus pneumoniae* (by immunochomatographic test)
  - *Cryptococcus neoformans* (by latex agglutination).

Culture

- **Bacteriological culture:** Ideal media for bacteriological culture of CSF are the enriched media like chocolate agar and blood agar.
  - Brain Heart Infusion (BHI) broth: As the bacterial load is very low, a part of the CSF should be enriched by inoculating into brain heart infusion (BHI) broth.
  - Blood culture can be carried out by inoculating the blood directly into blood culture bottles.
  - Biochemical tests: Colonies grown on solid media should be subjected to biochemical tests for identification of the organism.
  - Antimicrobial susceptibility test should be done for initiation of definite therapy.
- **Fungal culture:** It is carried out by inoculating the CSF on SDA (Sabouraud's dextrose agar) or BHI agar.
- **Viral culture:** Can done by inoculating the CSF onto appropriate cell lines.

Serological Test (Antibody Detection)

Antibody detection in serum may be useful for the diagnosis of underlying viral etiology; for example, detection of serum antibody against herpes simplex virus.

Bacterial Endotoxin Detection

Limulus lysate assay is widely used to detect endotoxins from gram-negative bacteria. The principle of this test—amoebocytes from the horseshoe crab (*Limulus polyphemus*) undergoing coagulation when added with the patient's blood containing endotoxin.

Molecular Methods

- If tubercular meningitis is suspected—PCR should be done to detect *Mycobacterium tuberculosis* specific genes such as IS 6110 gene.
- If pyogenic meningitis is suspected—multiplex PCR can be performed on CSF specimen by using multiple primers to detect the common etiological agents such as *S.pneumoniae,* meningococcus, *H.influenzae* etc.

BLOOD STREAM INFECTIONS

Blood stream infections (BSI) refer to presence of microorganisms in blood, which are a threat to every organ in the body.

- Microbial invasion of blood stream can have serious immediate consequences such as shock, multiple organ failure, and DIC (disseminated intravascular coagulopathies).
- Therefore, timely detection of the causative agent is one of the most important goals of microbiology laboratory.
- All four categories of microbes (bacteria, viruses, fungi and parasites) can cause BSI; however as bacteria account for the majority of BSI, bacterial causes of BSI are addressed here.

Bacteremia and Septicemia

- **Bacteremia** refers to the presence of bacteria in blood without any multiplication.
- **Septicemia** is a condition in which bacteria circulate and actively multiply in the bloodstream (and may produce their products, e.g. toxins) that cause harm to the host.

There are Three Types of Bacteremia

1. **Transient bacteremia:** It may occur spontaneously or with minor events such as brushing teeth or chewing food, instrumentation of contaminated mucosal site and surgery involving non-sterile site. These circumstances may also lead to septicemia.
2. **Continuous bacteremia:** Here, the organisms are released into the bloodstream at a fairly constant rate. It occurs in conditions such as:
   - Septicshock, endocarditis and other endovascular infections.
   - During the early stage of certain infections including enteric fever, brucellosis, and leptospirosis.
3. **Intermittent bacteremia:** In most other infections, bacteria are released into blood intermittently.
   - Undrained abscess (bacteria are released approximately 45 minutes before a febrile episode)
   - Early course of meningitis, pneumonia, pyogenic arthritis and osteomyelitis.

Types of Bloodstream Infections (BSI)

There are two major categories of bloodstream infections—intravascular and extravascular.

Factors that contribute to the initiation of BSI are:

- Immunosuppression
- Use of broad spectrum antimicrobial agents can supress the normal flora; thus allowing the emergence of resistant strains of bacteria.
- Invasive procedures or extensive surgeries that allow the bacteria to access the blood
- Prolonged survival of debilitated patients.

Intravascular Bloodstream Infections

Intravascular infections are those that originate within the cardiovascular system which include:

- Infective endocarditis
- Mycotic aneurysm
- Suppurative thrombophlebitis
- Intravenous catheter associated bacteremia

These infections being present within the vascular system, lead to continuous bacteremia which result into serious and life threatening events.

Infective Endocarditis

It is the infection of endocardium, characterized by presence of '*vegetation*' which is composed of mass of platelets, fibrin, micro colonies of organisms, and scanty inflammatory cells.

- Vegetations are most commonly present in heart valves followed by low-pressure side of a ventricular septal defect, and on the mural endocardium
- Endocarditis may be classified as:
  - Onset-acute (rapidly damages the cardiac structures, and spread to extracardiac site, rapidly fatal) or subacute (slow evolution, metastasizes slowly)
  - Type of valve affected—can occur in native or in prosthetic valve
  - May be associated with intravenous drug abuse
- The etiological agents of endocarditis depend on the type of endocarditis (Table 54.12).

Extravascular Bloodstream Infections

Most cases of clinically significant bacteremia are of extravascular origin.

- The organisms multiply at the primary site such as lungs, and drained by lymphatics and reach the bloodstream.
- The organisms are either removed by the cells of the reticuloendothelial system or they multiply more widely and thereby causing septicemia.
- **Portal of entry:** The most common portals of entry for bacteremia are the genitourinary tract (25%), followed by respiratory tract (20%), abscesses (10%), surgical site

wound infections (5%), and biliary tract (5%). In upto 25% of cases, the portal of entry remains uncertain.

- **Agents:** The organisms invading the bloodstream depend upon the portal of entry and have been listed in table 54.13.

TABLE 54.12: Agents of Endocarditis

Agents of endocarditis
▪ Streptococci (Viridans streptococci and others) ▪ Pneumococci ▪ Enterococci ▪ *Staphylococcus aureus* ▪ Coagulase-negative staphylococci ▪ (e.g. *Staphylococcus epidermidis)* ▪ Fastidious gram-negative coccobacilli (HACEK group) ▪ Gram-negative bacilli ▪ *Candida* species ▪ Diphtheroids ▪ Culture-negative endocarditis: Such as *Bartonella, Coxiella*
Most common agent in specific types of endocarditis
Native valve endocarditis: *Staphylococcus aureus*
Prosthetic valve endocarditis: It occurs following cardiac valve replacement ▪ Early prosthetic valve endocarditis (occurs within 12 months of valve replacement)—*Staphylococcus epidermidis* is the commonest agent ▪ Late prosthetic valve endocarditis (occurs after 12 months of valve replacement)—Viridans streptococci is the commonest agent
Endocarditis in IV drug abusers: Young males are the most common victims. The skin is the commonest source of infection. ▪ Right sided: Most common agent is *Staphylococcus aureus* ▪ Left sided: Most common agent is *Enterococcus*, followed by *S.aureus* ▪ Over all: Most common agent is *Staphylococcus aureus*
Most common cause of Subacute endocarditis: Viridians streptococci

TABLE 54.13: Bacteria causing extravascular blood stream infection (BSIs) and their common sources

Organisms	Portal of entry/sources
E.coli and other gram-negative bacteria such as *Klebsiella, Proteus, Enterobacter, Pseudomonas*	Urinary tract (most common), Intestine (rarely)
Haemophilus influenzae-b	Meninges, epiglottis, lungs
Pneumococcus	Meninges, lungs
Brucella	Reticuloendothelial system
Salmonella Typhi	Small intestine, lymph nodes and reticuloendothelial system
Listeria	Intestine, meninges
Staphylococcus aureus and coagulase negative staphylococci	Surgical site infections

Clinical Manifestations

The manifestations due to bloodstream infection are evident in the septicemic stage, where the bacteria multiply releasing their products (e.g. toxins). The common signs and symptoms include:

- Fever or hypothermia with/without chills and rigors
- Hyperventilation leads to excess loss of CO_2 and subsequent respiratory alkalosis
- Skin lesions, change of mental status and diarrhea
- **Septic shock:** This is the gravest late stage complication of septicemia and is manifested as—hypotension, DIC and multiorgan failure (e.g. acute respiratory distress, renal failure, tissue destruction, etc.). The endotoxins of gram-negative bacteria have a direct effect on the pathogenesis of septic (or endotoxic) shock.

Laboratory Diagnosis

Diagnosis of bloodstream infection depends on isolation of the causative agent from blood.

Specimen Collection

- **Site:** Usually blood is collected from antecubital vein, at a point below the existing IV line (if present), as blood above the IV line usually gets diluted with the fluid being infused.
- **Preparation of site:** To avoid contamination with skin flora, blood should be collected under strict aseptic conditions using sterile disposable syringe.
- **Antiseptics:** Skin should be treated with 70% isopropyl alcohol and then an antiseptic solutions, such as tincture iodine or chlorhexidine should be applied.
- **Timing of collection:** Blood should be collected before starting antimicrobial therapy.
- **Blood volume:** Higher the volume of blood, greater is the yield of isolation (yield increases by 3.2% per mL of blood cultured). At least 10–20 mL per culture is recommended for adults.
- **Number of blood cultures:** This depends on periodicity of bacteremia.
  - When continuous bacteremia is expected—single blood culture collected before start of antibiotics would give a positive result in 90-95% cases.
  - In other situations—2–3 blood cultures are required to have good isolation chances (around 65%, 80% and 95% with one, two and three specimens respectively).

Culture Medium

Blood culture broths in bottles are the recommended media. There are two types of media:

- **Monophasic medium:** It contains 50–100 mL of brain heart infusion (BHI) broth.
- **Castaneda's biphasic medium:** It consists of BHI agar slope and BHI broth (50–100 mL)
- **Dilution:** The blood is inoculated in the medium at a dilution of 1:5 so that the antibacterial components in the blood, if any, will get diluted.
- **SPS** (sodium polyanethol sulfonate) is added to the medium as anticoagulant. It also counteracts the bactericidal action of blood.

Inoculation and Incubation

10–20 mL of fresh blood is directly injected at the bedside through the rubber cap of the bottle, rather than opening the bottle (to avoid contamination from the external environment) and then it is incubated at 37°C for up to 7 days.

Repeat Subcultures

- **From monophasic medium:** Repeat subcultures are made onto blood agar and MacConkey agar when the broth becomes turbid or periodically (blind subcultures) for one week. There is a risk of contamination due to opening of the cap of the bottle every time when subcultures are made.
- **Biphasic medium** is preferred as the subcultures can be made just by tilting the bottles so that the broth runs over the agar slope. Bottle is incubated in the upright position. If colonies appear over the agar slant, colonies are picked up and used for further identification.

Identification

The isolated organism is identified by colony morphology, Gram staining, biochemical reactions and serological tests.

Antimicrobial Susceptibility Test

Antimicrobial susceptibility test by disk diffusion method is carried out for institution of appropriate therapy. However for endocarditis, determining the MIC (minimum inhibitory concentration) is the ideal method, especially when tested against penicillin.

FEVER OF UNKNOWN ORIGIN (FUO)

Definition

Petersdorf and Beeson Classification

Petersdorf and Beeson had defined fever of unknown origin (FUO) in 1961 as patients having:

- Temperatures of more than 38.3°C (more than 101°F)
- For a duration of more than 3 weeks; and
- Failure to reach a diagnosis despite 1 week of inpatient investigation.

This classification has stood for more than 30 years, but later in 1990s, it was revised.

Durack and Street Classification

Durack and Street (1990) have proposed a revised system for classification of FUO that better accounts for non-endemic and emerging diseases and improved newer diagnostic facilities. This updated classification includes four types of FUO (Table 54.14).

Causes

- **Infections (36%):** This accounts for majority of FUO cases. All groups of microbial infections (both localized and systemic) can cause FUO (Table 54.15).

TABLE 54.14: Classification of fever of unknown origin

Durack and Street definition of fever of unknown origin (FUO)
▪ **Classic FUO** (corresponds closely to the earlier definition of FUO): • Temperatures of >38.3°C (>101°F) • Duration of fever >3 weeks • Three outpatient visits or 3 days in the hospital without elucidation of a cause or 1 week of intelligent and invasive ambulatory investigations
▪ **Nosocomial FUO:** • Temperature of >38.3° C (101°F) develops in a hospitalized patient; in whom infection was not manifested or incubating on admission • Three days of investigation, including at least 2 days of incubation of cultures—reveals no source
▪ **Neutropenic FUO** is defined as: • Temperature of >38.3°C (101°F) • Neutrophil count is <500/μL • Three days of investigation, including at least 2 days of incubation of cultures—reveals no source
▪ **HIV-associated FUO** is defined as: • Temperature of >38.3°C (101°F) for >4 weeks for outpatients or >3 days for hospitalized patients • HIV infection has been confirmed • Three days of investigation, including at least 2 days of incubation of cultures—reveals no source

Abbreviations: FUO, fever of unknown origin; HIV, human immunodeficiency virus

TABLE 54.15: Causes of fever of unknown origin

Bacterial causes		Non-bacterial causes		
Localized pyogenic infections	**Systemic bacterial infections**	**Viral infections**	**Parasitic infections**	**Fungal infections**
▪ Appendicitis ▪ Cholangitis ▪ Cholecystitis ▪ Localized abscess ▪ Mesenteric lymphadenitis ▪ Osteomyelitis ▪ Pelvic inflammatory disease ▪ Sinusitis ▪ Suppurative thrombophlebitis ▪ Intravascular infections	▪ Mycobacterial infections ▪ Typhoid fever ▪ Rickettsial infections ▪ *Mycoplasma* infections ▪ Chlamydial infections ▪ Brucellosis ▪ Melioidosis ▪ Listeriosis ▪ Bartonellosis ▪ Spirochete infections: • Syphilis • Lyme disease • Relapsing fever • Leptospirosis	▪ Chikungunya fever ▪ Dengue fever ▪ Cytomegalovirus and EBV infection ▪ Coxsackievirus group B infection ▪ Viral hepatitis ▪ HIV infection	▪ Malaria ▪ Amoebiasis ▪ Leishmaniasis ▪ Chagas'disease ▪ Toxoplasmosis ▪ Strongyloidiasis	▪ Aspergillosis ▪ Mucormycosis ▪ Blastomycosis ▪ Histoplasmosis ▪ Coccidioidomycosis ▪ Paracoccidioidomycosis ▪ Candidiasis ▪ Cryptococcosis ▪ *Pneumocystis* infection ▪ Sporotrichosis

Abbreviations: EBV, Epstein-Barr virus; HIV, human immunodeficiency virus

- **Neoplasms (19%):** e.g. lymphoma, leukemia, myeloma, renal, colon and liver cancers, etc.
- **Non-infectious Inflammatory Diseases (19%):** E.g. connective tissue disorders like rheumatoid arthritis, SLE (systemic lupus erythematosus), etc.
- **Miscellaneous Causes (19%)**
  - Granulomatous diseases
  - Inherited and metabolic diseases
  - Thermoregulatory disorders
- Undiagnosed cases (7%)

Laboratory Diagnosis

Specimen Collection

Prior to specimen collection, a complete clinical history (including details of travel, immunization, exposure to any other patients) and physical examination should be carried out that may be helpful in choosing the appropriate specimen such as blood, urine, bone marrow aspirate, pus from abscesses, etc.

Microscopy

- **Blood microscopy:** Useful for detection of malaria parasites (ring forms and gametocytes), microfilariae, *Leishmania donovani* (LD bodies or amastigote forms), and trypanosomes (trypomastigote forms).
- **Stool wet mount:** For detection of cyst ,trophozoitie or ova of parasitic agent of FUO (e.g. *Entamoeba histolytica*).
- **Gram stain** of pus, sputum and other specimen can be carried out for detection of the causative agent (e.g. gram-negative coccobacilli may be suggestive of *Brucella*).
- **Ziehl Neelsen stain:** For *M.tuberculosis.*
- Periodic acid-schiff (PAS) or Gomori methenamine silver (GMS) stain for detection of fungal morphology.

Culture

- Blood culture is done for typhoid fever, brucellosis.
- Culture on Lowenstein Jensen medium is done for *M.tuberculosis.*
- Culture of pus and exudate specimen from the abscesses—for detection of the causative agent.
- Sabouraud dextrose agar (SDA) culture—for fungal isolation.
- Cell line culture: Culture in appropriate cell lines is useful for the isolation of virus, e.g. human diploid cell line for cytomegalovirus (CMV).

Serological Test

- ELISA and rapid tests for viral diseases such as hepatitis, HIV, CMV, EBV infections, etc.
- Standard agglutination test—for brucellosis.
- Microscopic agglutination test—for leptospirosis.
- Cold agglutination test—for *Mycoplasma.*
- Weil Felix test—for rickettsial diseases.
- Paul-Bunnell test—for infectious mononucleosis.
- Widal test—for typhoid fever.
- Micro immunofluorescence test or complement fixation test (CFT) for chlamydial infections.
- Rheumatoid arthritis (RA) factor—for rheumatoid arthritis.

- Antinuclear antibody detection by immunofluorescence or ELISA for diagnosis of SLE.

Molecular Tests

If the infective organism load is very low, PCR can be carried out to amplify the specific genes, even if few copies are present will be detected.

Other Tests

- **Complete blood count:** Increased neutrophil count indicates pyogenic infections.
- **Raised ESR (erythrocyte sedimentation rate):** It may indicate tuberculosis.
- Histopathological examinations of the biopsies obtained from tumors may suggest the underlying etiology.
- **Imaging methods:** Chest X ray (for diagnosis of tuberculosis) and CT or MRI scan to identify the malignant tumours and their extension.
- ECG for rheumatic fever and endocarditis.

RESPIRATORY TRACT INFECTION

Infections involving the respiratory tract can be further classified into—upper and lower respiratory tract infections.

Upper Respiratory Tract Infections

Upper respiratory tract infections (URI or URTI) includes infections of the airway above the glottis or vocal cords. This includes the nose, sinuses, pharynx, and larynx.

- Typical infections of the upper respiratory tract include tonsillitis, pharyngitis, laryngitis, sinusitis, otitis media, and rhinitis.
- Symptoms of URIs can include cough, sore throat, runny nose, nasal congestion, headache, low grade fever, facial pressure and sneezing

Common aetiological agents of URTI are listed in table 54.16.

TABLE 54.16: Microorganisms causing upper respiratory tract infections (URTI)

Rhinitis or common cold	Pharyngitis (sore throat), and tonsillitis	Laryngitis	Laryngotracheobronchitis (or croup)

Mostly caused by viruses:
▪ Rhinovirus
▪ Coronavirus
▪ Adenovirus
▪ Influenza virus
▪ Parainfluenza virus
▪ Human metapneumovirus
▪ Respiratory syncytial virus
 	
Sinusitis
Inflammation of the sinuses (due to allergy or infections)
Symptoms:
▪ Headache/facial pain
▪ Thick nasal mucus,
▪ Plugged nose
Agents of acute sinusitis:
Viruses (most common cause):
▪ Rhinoviruses,
▪ Influenza viruses,
▪ Parainfluenza viruses
Bacterial agents
▪ *Streptococcus pneumoniae*
▪ *Haemophilus influenzae*
▪ *Moraxella catarrhalis*
▪ *Pseudomonas* and other gram-negative bacilli (nosocomial sinusitis)
Agents of chronic sinusitis:
▪ Obligate anaerobes
▪ *Staphylococcus aureus*
	Symptoms:
	Pharynx and/or tonsils become inflamed, red, swollen, and show exudate, and sometimes a membrane is formed
	Viruses:
	(most common cause)
	▪ Influenza virus
	▪ Parainfluenza virus
	▪ Coxsackievirus A
	▪ Rhinovirus
	▪ Coronavirus
	▪ Epstein-Barr virus
	▪ Adenoviruses
	Bacteria:
	▪ *Streptococcus pyogenes* (most common bacterial cause)
	▪ *Streptococcus* groups C and G
	▪ *Arcanobacterium* species
	▪ *Corynebacterium diphtheriae, C.ulcerans*
	▪ *Mycoplasma pneumoniae*
	▪ Vincent angina
	  ▪ *Treponema vincentii*
	  ▪ *Leptotrichia buccalis*
	Fungal:
	Candida albicans
		Symptoms:
		▪ Hoarseness of voice
		▪ Lowering and deepening of voice
		Mostly viral agents:
		▪ Influenza virus
		▪ Parainfluenza virus
		▪ Rhinovirus
		▪ Adenovirus
		▪ Coronavirus
		▪ Human metapneumovirus
		If membrane or exudate present:
		▪ *Streptococcus pyogenes*
		▪ *C.diphtheriae*
		▪ Epstein-Barr virus
			Age- Children, < 3 years age
			Symptoms:
			▪ Inspiratory stridor (high-pitched breath sound resulting from turbulent air flow in the larynx)
			▪ Hoarseness
			▪ Fever
			▪ Cough (harsh, barking non-productive)
			Agents:
			▪ Parainfluenza virus (most common)
			▪ Influenza virus
			▪ Respiratory syncytial virus
			▪ Adenoviruses
			
			Epiglottis
			Edema and inflammation of epiglottis and soft tissue above vocal cords
			Age: children 2–6 years
			Symptoms:
			▪ Fever,
			▪ Difficulty in swallowing
			▪ Inspiratory stridor
			Most common agent:
			Haemophilus influenzae type b

TABLE 54.17: Organisms causing Lower respiratory tract infections (LRTI)

Pneumonia		Bronchitis	Bronchiolitis
Community acquired	**Hospital acquired**		
Bacterial agents: ▪ *Streptococcus pneumoniae* ▪ *Mycoplasma pneumoniae* ▪ *Haemophilus influenzae* ▪ *Chlamydophila pneumoniae*	**Bacterial agents:** ▪ *S. pneumoniae* ▪ *M. pneumoniae* ▪ *Chlamydophila pneumoniae* ▪ *H. influenzae* ▪ *Legionella* species ▪ *Staphylococcus aureus* ▪ Gram-negative bacilli	**Bacterial agents** ▪ *B. pertussis* ▪ *B. parapertussis* ▪ *Mycoplasma pneumoniae* ▪ *Chlamydophila pneumoniae*	**Viral agents** ▪ Respiratory syncytial viruses ▪ Parainfluenza viruses ▪ Rhinoviruses ▪ Influenza viruses ▪ Adenoviruses ▪ Enterovirus ▪ Human metapneumovirus
Respiratory viruses ▪ Influenza viruses ▪ Adenoviruses ▪ Respiratory syncytial viruses ▪ Parainfluenza viruses	Respiratory viruses (same as for community acquired pneumonia).	**Viral agents** ▪ Influenza viruses ▪ Adenoviruses ▪ Rhinoviruses ▪ Coronaviruses	

Lower Respiratory Tract Infection

The infections of trachea, bronchi, bronchioles, and the lungs are called as lower respiratory tract infections (LRI or LRTI). These include bronchitis, bronchiolitis, pneumonia, and lung abscesses (Table 54.17).

Pneumonia

Pneumonia refers to inflammation of lungs which can be classified into: (1) community acquired—patients acquire the organisms in the community, (2) hospital acquired—patients acquire the organisms in the hospital setting.

Clinical Manifestations

The common manifestations include fever, chills, chest pain and cough. Based on area of lungs involved, and type of cough produced, pneumonia can be grouped into:

- **Lobar pneumonia** infecting lung parenchyma (alveoli): It is characterized by consolidation and productive cough (purulent sputum). It is mostly caused by pyogenic organisms such as:
  - Pneumococcus
  - *Haemophilus influenzae*
  - *Staphylococcus aureus*
  - Gram-negative bacilli
- **Interstitial or atypical pneumonia** infection occurs in interstitial space of lungs. Cough is characteristically non-productive. It is mostly caused by organisms such as:
  - *Chlamydophila pneumoniae*
  - *Mycoplasma pneumoniae*
  - Viral pneumonia
  - *Legionella* species
- **Bronchitis:** Bronchitis is characterized by inflammation of bronchus, which occurs either as an extension of upper respiratory tract infection such as influenza or may be caused directly by bacterial agents such as *Bordetella*. Common symptoms include fever, cough, sputum production, and rarely croup-like features.
- **Bronchiolitis:** Bronchiolitis is inflammation of the smaller airways (bronchioles). It presents as an acute viral infection that primarily occurs in children less than 2 years.
  - It is characterized by acute onset of wheeze, dyspnea, cough, rhinorrhea, and respiratory distress.
  - Respiratory syncytial viruses account for 40–80% of the infections.

Oral Cavity Infection

- **Stomatitis:** Inflammation of the mucus membrane of oral cavity
  - Most common agent: Herpes simplex virus
  - Symptom: Painful vesicular ulcers
- **Oral thrush:** It is characterized by whitish patch of exudate in the oral cavity.
  - Agent: *Candida albicans*
  - Risk factor: Immunosuppression
- **Periodontal infections:** Root canal infections and perimandibular infections mainly caused by:
  - Anaerobic bacteria (*Bacteroides fragilis*)
  - Streptococci (*S. sanguis*)
  - *S. aureus*
  - *Eikenella corrodens*
- **Salivary gland infections:** Parotitis is characterized by painful tender swelling of the parotid glands. The most common cause is *Staphylococcus aureus*, whereas most common viral agent is mumps.

Laboratory Diagnosis of Respiratory Tract Infections

Specimen Collection

Depending upon the nature of the disease, various respiratory specimens collected are:

- **For URTI**:
  - Throat swab—two swabs should be collected, one for direct examination, other one for culture

- A part of the membrane, if present
- Nasopharyngeal aspirate for viral diagnosis or for *B.pertussis*.

- **For LRTI:** Sputum, induced sputum, tracheal aspirate, bronchoalveolar lavage (BAL)

Microscopy

- **Albert staining** of the throat swab may demonstrate the presence of metachromatic granules in the ends of the bacilli—suggestive of *C.diphtheriae*
- **Gram staining** of the sputum or other specimens is done to:
  - Detect the quality of the sputum: If many pus cells are present (>25/low power field) and less epithelial cells are present (<5/low power field), such samples are regarded as good quality sputum, where the chance of recovery of the pathogen is more.
  - Identify bacteria based on their morphology—for example, gram-positive cocci, pair, lanceolate shaped- suggestive of pneumococcus
- **Acid fast staining** of sputum by Ziehl Neelsen technique is performed to demonstrate the acid fast bacilli e.g. *M.tuberculosis*.
- **GMS stain** (Gomori methenamine silver stain) is used to demonstrate *Pneumocystis jerovecii*.
- **Immunofluorescence microscopy** of nasopharyngeal aspirate is performed to detect the presence of antigens of respiratory viruses.

Culture

- **For bacteriological culture:** Specimens are inoculated onto blood agar, chocolate agar and MacConkey agar and incubated overnight with 5% CO_2.
- **For isolation of *C. diphtheriae*:** Loeffler's serum slope and potassium tellurite agar are used.
- **For *M.tuberculosis*:** Specimen should be inoculated onto LJ medium and incubated for up to 6–8 weeks.
- **For fungal pathogen isolation:** Sabouraud Dextrose Agar is used.
- **Appropriate cell lines** are sometimes used for the isolation of the respiratory viruses

Identification

- Specific bacterial identification is done based on colony morphology, and biochemical reactions.
- Viral agents in the cell lines can be detected by demonstration of cytopathic effect or detection of viral antigens by immunofluorescence test.

Serology

This is important for detection of antibodies:

- ***Mycoplasma*:** Cold agglutination test, complement fixation test (CFT) and ELISA formats are available.
- **Chlamydial antibodies in serum:** Micro-IF and CFT are used
- Most viral infections.

Molecular Test

Multiplex PCR assays are available where multiple primers targeting the genes specific for each of the suspected agents of URTI/LRTI are used.

Skin, Soft Tissue and Wound Infections

Approximately 15% of all patients who seek medical attention have some skin diseases or lesions, and many of which are infectious.

- Skin infections can arise from invasion of organism through skin or from organisms that reach the skin from blood as a part of systemic infection.
- Skin comprises of dermis, epidermis and subcutaneous issues. Hair follicles and sweat glands originate in the subcutaneous tissues. Infection can involve any of these layers of skin (Table 54.18).

Skin Lesions

Skin infections can be subdivided into primary and secondary lesions:

- **Primary lesion:** An area of tissue with impaired structure/function due to damage by trauma or disease.
- **Secondary lesion:** A lesion arising as a consequence of any primary lesion.

Agents implicated in surgical site infections and burn wound infections are listed in Table 54.19 and 54.20 respectively.

Laboratory Diagnosis

Specimen Collection

Appropriate specimens include:

- Pus from the wound collected by sterile swab
- Pus from abscess collected by incision and drainage, or needle aspiration
- Vesicle or bulla fluid, collected by needle aspiration or sterile swab
- Subcutaneous infections: Sample collected from the base of the lesion or biopsy of the deep tissues
- Skin scrapings, plucked hair or nail clippings in suspected fungal infections.

Microscopy

- Gram staining of the specimen may demonstrate the morphology of the causative organisms.
- KOH mount is done for suspected fungal infections (e.g. dermatophyte)
- Tzanck smear of the vesicle fluid suspected of herpes simplex or varicella virus infections.

TABLE 54.18: Infective skin manifestations and their common causative agents

Skin lesions	Description	Common etiological agents
Macule	Flat, non-palpable discoloration of skin (<5cm size). If size exceeds 5 cm, is called as patch.	Dermatophytes Viral rashes (e.g. enterovirus)
Papule	Elevated lesions usually < 5 mm in size that can be felt or palpated	Molluscum contagiosum Scabies (*Sarcoptes scabiei*) Warts (Human Papilloma virus)
Plaque	Multiple papules my become confluent to form plaque which are palpable lesions > 5 mm	
Nodule	Firm lesions >5cm size	*Staphylococcus aureus* *Sporothrix* *Mycobacterium marinum*
Vesicle	Fluid-filled lesions with a diameter less than 0.5 cm	Herpes simplex virus, Varicella-zoster virus
Bulla	Fluid-filled lesions with a diameter more than 0.5 cm	*Clostridium* Herpes simplex virus *Staphylococcus aureus*
Pustule	A fluid-filled vesicle containing neutrophils (i.e. pus) and is less than 0.5cm in diameter	*Candida* *Staphylococcus aureus* *Streptococcus pyogenes*
Abscess	A fluid-filled lesion containing neutrophils and is more than 0.5 cm in diameter	
Secondary lesions		
Scale	Excess dead epidermal layer	Dermatophytes *Streptococcus pyogenes*
Ulcer	Break in epithelial lining extending into the epidermis/dermis	*Bacillus anthracis* decubitus ulcers of leprosy
Erysipelas	Painful, red, indurated swollen lesion involving dermis with a well marked raised border Associated fever and lymphadenopathy	*Streptococcus pyogenes* Other streptococci
Impetigo	Erythematous lesions which may be bullous or non-bullous with exudates and golden-yellow crusts	Non-bullous: *Streptococcus pyogenes* Bulllous: *Staphylococcus aureus*
Cellulitis	Diffuse spreading infection involving deep layers of dermis. Ill-defined flat red, painful lesions Associated fever and lymphadenopathy	*Streptococcus pyogenes* *Staphylococcus aureus* Less common: *Aeromonas, Vibrio, H.influenzae*
Hidradenitis	Chronic infection of obstructed sweat glands	*Staphylococcus aureus* *Streptococcus angionosus* group
Hair follicle infections		
Folliculitis	Superficial infection of single hair follicle, presents as pustule	*Staphylococcus aureus*
Furuncle	Deeper infections of the hair follicles, presents as abscess, spread deeply into dermis and subcutaneous tissues	
Carbuncle	represent the coalescence of a number of furuncles	
Infection of fascia and muscles		
Necrotizing fasciitis	Rapidly spreading infection of fascia	*Streptococcus pyogenes*
Pyomyositis	Pus formation in the muscle layer	*Staphylococcus aureus* *Streptococcus pyogenes*
Myonecrosis	Extensive necrosis of the muscle layer with gangrene formation	Clostridial myonecrosis Other anaerobic infections

TABLE 54.19: Agents causing surgical site wound infection

Bacterial agents	Fungi
For most clean wounds: ▪ *Staphylococcus aureus* ▪ Coagulase negative *Staphylococcus* ▪ *Enterococcus*	*Candida albicans*
If bowel integrity is compromised: ▪ Gram-negative flora like *E.coli* and ▪ Anaerobic organisms like *Bacteroides, Prevotella,* etc	

TABLE 54.20: Agents causing burn wound infections

Bacteria	Fungi
Staphylococcus aureus (may be MRSA) *Pseudomonas aeruginosa* Coagulase negative *Staphylococcus (e.g. S.epidermidis)*	*Candida albicans*

Abbreviation: MRSA, methicillin resistant *staphylococcus* anreus

Culture

- For the culture of aerobic bacteria, specimens are inoculated onto blood agar and MacConkey agar and incubated overnight at 37°C.
- For culture of atypical *Mycobacterium*—Lowenstein Jensen medium may be used.
- For dermatophytes—Sabouraud's dextrose agar is used.
- For anaerobic organisms—Robertson's cooked meat broth and BHIS (brain heart infusion agar with supplements) should be used. The plates should be incubated anaerobically.

Quantitative Culture

As the degree of bacterial contamination of the wound, is directly related to the chance of development of wound sepsis, hence quantitative culture may be performed to determine the number of colony forming units/gram of the tissue collected from the wound.

Identification

Accurate identification of the causative agent is done based on colony morphology, culture smear, and biochemical reactions.

Antimicrobial Susceptibility Test

It helps in initiation of appropriate therapy.

SEXUALLY TRANSMITTED INFECTIONS

The sexually transmitted infections (STIs) are a group of communicable diseases which are transmitted by sexual contact. Causative agents of STIs may be classified into two groups:

1. Agents causing local manifestations such as:
   - Genital ulcers
   - Urethral discharge
   - Vaginal discharge
   - Genital warts
   - Pelvic inflammatory diseases
2. Agents transmitted by sexual route, producing only systemic manifestations and do not cause local manifestations (e.g. HIV).

Laboratory Diagnosis of STIs

Specimen Collection

- Discharge from the infected area such as vaginal or urethral discharge are collected in a sterile container.
- Sterile swabs may be used to collect the discharge (if scanty): Charcoal impregnated swabs are used for suspected gonococcal infection.
- Fluid from the vesicles (genital herpes).

Microscopy

- **Wet mount examination:** It is carried out for the vaginal discharge
  - In trichomoniasis: Pus cells along with motile trophozoites are seen
  - In candidiasis: Yeast cells along with pseudohyphae are seen
- **Gram-stained smear** of the discharge or the swab is useful for:
  - Bacterial vaginosis—clue cells are seen, which are vaginal epithelial cells studded with gram variable pleomorphic coccobacilli: suggestive of *Gardnerella vaginalis*
  - In gonorrhoea—intracellular kidney shaped diplococci are seen
  - In candidiasis—gram-positive budding yeast cells along with pseudohyphae are seen.
- **Giemsa stain** is done for:
  - *Klebsiella granulomatis* to detect the presence of Donovan's bodies (macrophage filled with bipolar stained bacilli)
  - *Chlamydia trachomatis* inclusion bodies
- **Dark field microscopy** and silver impregnation methods —in syphilis, reveals characteristic spirally coiled bacilli

The microorganisms causing STIs are listed in Table 54.21 and the important features of STIs producing genital ulcers are compared in Table 54.22.

Culture

Specimens are inoculated onto the appropriate culture media or cell line for the isolation of the causative organism.

- Thayer martin medium—for *N.gonorrhoeae*
- Chocolate agar added with isovitalex and vancomycin—for *H.ducreyi*

TABLE 54.21: Causative agents of sexually transmitted infections (STIs)

Agents causing local manifestations	
Genital ulcers	
Syphilis	*Treponema pallidum*
Herpes genitalis	Herpes simplex viruses type 2 &1
Chancroid	*Haemophilus ducreyi*
Lymphogranuloma venereum	*Chlamydia trachomatis*
Donovanosis	*Klebsiella granulomatis*
Urethral discharge	
Gonorrhoea	*Neisseria gonorrhoeae*
Non-gonococcal urethritis (NGU)	*Chlamydia trachomatis* (D-K) *Ureaplasma urealyticum* *Mycoplasma genitalium* *Mycoplasma hominis* Herpes simplex virus *Candida albicans* *Trichomonas vaginalis*
Vaginal discharge	
Vulvovaginal Candidiasis	*Candida albicans* Non-albicans *Candida* species
Bacterial vaginosis	*Gardnerella vaginalis* *Mobiluncus* species
Trichomonal Vaginitis	*Trichomonas vaginalis*
Genital warts	
Condyloma acuminata	Human papilloma viruses
Agents causing systemic manifestations	
Pelvic inflammatory diseases (PID)	*Neisseria gonorrhoeae* *Chlamydia trachomatis*
No genital lesions but only systemic manifestations	HIV Hepatitis B virus (HBV) Hepatitis C virus (HCV)

- McCoy cell line—for *Chlamydia trachomatis*
- Sabouraud's dextrose agar(SDA)—for *Candida* species.
- Cell lines such as Vero cells, a monkey kidney cell line for herpes simplex virus

Serology

Serological tests such as venereal disease research laboratory (VDRL) or rapid plasma reagin (RPR) can be performed for the diagnosis of primary syphilis.

Molecular Test

Multiplex PCR assays are available where multiple primers targeting the genes specific for each of the suspected agents of STI are used.

CONGENITAL INFECTIONS

Vertical transmission refers to the spread of infections from mother-to-baby. These infections may occur by transplacental route (congenital infection), during delivery, or after delivery.

Congenital Infection

A congenital infection is an infection that crosses the placenta to infect the fetus. They often lead to defects in fetal development or even death.

TORCH is an acronym used for some common congenital infections. These are:

- **T**oxoplasmosis
- **O**ther infections (congenital syphilis, hepatitis B, Coxsackie virus, Epstein-Barr virus, varicella-zoster virus, *Plasmodium falciparum* and human parvovirus)
- **R**ubella
- **C**ytomegalovirus (CMV)
- **H**erpes simplex virus

Perinatal Infections (During Delivery)

Perinatal infections occur while the baby moves through an infected birth canal. These infections are usually caused by the agents of STIs. These also include the infections transmitted through contamination with fecal matter during delivery. Common examples of agents causing perinatal infections include:

- CMV
- *Neisseria gonorrhoeae*
- *Chlamydia* species
- Herpes simplex virus

TABLE 54.22: Comparison of sexually transmitted diseases (STDs) producing genital ulcer

Feature	Syphilis	Herpes	Chancroid	LGV	Donovanosis
Incubation period	9–90 days	2–7 days	1–14 days	3 days–6 weeks	1–4 weeks (up to 6 months)
Genital ulcer	Painless, indurated, single	Multiple, painful	Painful, soft Single or multiple	Painful, soft	Painless
Lymphadenopathy	Painless, moderate swelling (no bubo)	Absence or moderate swelling (no bubo)	Painful, soft, marked swelling leads to bubo formation	Painless	Absent (pseudo bubo may be present due to subcutaneous swelling)

Abbreviation: LGV, Lymphogranuloma venereum

- Human papilloma virus (genital warts)
- Group B streptococci

Postnatal Infections (After Delivery)

These infections spread from mother to baby following delivery, usually during breast feeding. Some examples of postnatal infections are: CMV, HIV and group B streptococci.

EYE INFECTIONS

In general, ocular infections are grouped into:

- **Infections involving external structures of the eyes:** such as eye lid (blepharitis), conjunctiva (conjunctivitis), cornea (keratitis) and sclera (scleritis)
- **Infections involving internal structures:** Retina (retinitis), uvea (uveitis) and aqueous humor or vitreous humor (endophthalmitis)

The list of the organisms causing various ocular infections is given in Table 54.23.

EAR INFECTIONS

Common ear infections are (Table 54.24)

- **Otitis externa:** Inflammation, irritation, or infection of the outer ear and ear canal.
  - Also called as swimmer's ear—swimming in contaminated water is one of the reasons of contracting swimmer's ear.
  - Symptoms—itchy ear canal, Inflammation of ear canal's skin and pus formation in ear canal and earache that is aggravated when the ear lobe is pulled.
- **Otitis media:** Infections of middle ear; characterized by earache and ear discharge.
  - It often begins with an infection that causes a sore throat, cold or respiratory problem and eventually spread to the middle ear.
  - Symptoms include: Intense earache, headache, fever and nausea and leaking of discharge from ear following rupture of the tympanic membrane.

TABLE 54.23: Ocular infections and their causative agents

Infections	Organisms
Blepharitis (Infection of eyelids)	*Staphylococcus aureus*
Conjunctivitis (Infection of conjunctiva)	*Haemophilus influenzae* *Staphylococcus aureus* *Chlamydia trachomatis* *Neisseria gonorrhoeae* Adenovirus, Herpes simplex virus
Keratitis (Infection of cornea)	*Staphylococcus aureus* *Streptococcus pneumoniae* *Moraxella lacunata* (angular keratitis) *Fusarium, Candida* *Acanthamoeba*
Scleritis (Infection of sclera)	*Staphylococcus aureus*
Chorioretinitis and uveitis (Infection of choroid, retina, and uvea)	*Mycobacterium tuberculosis* *Treponema palladium* *Borrelia burgdorferi* Cytomegalovirus *Toxoplasma gondii*
Endophthalmitis (Infection of aqueous humor or vitreous humor)	*Staphylococcus aureus* *Streptococcus pneumoniae* *Pseudomonas aeruginosa* Other gram-negative bacilli Herpes simplex virus, *Candida*

TABLE 54.24: Organisms causing ear infections

Otitis externa: Infection of external ears
Acute otitis externa ▪ *Staphylococcus aureus* (most common) ▪ *Streptococcus pyogenes* ▪ *Pseudomonas* (malignant otitis externa) ▪ Other gram-negative bacilli ▪ *Aspergillus* species ▪ *Candida* species
Chronic otitis externa ▪ Anaerobes (most common) ▪ *Pseudomonas*
Otitis media: (middle ear infections)
Acute otitis media *Streptococcus pneumoniae*: Most common (33%, in children) *Haemophilus influenzae* type b (second most common) *Moraxella catarrhalis* *Streptococcus pyogenes* Respiratory syncytial virus Influenza virus
Chronic otitis media Anaerobes (most common)

EXPECTED QUESTIONS

I. Write short notes on:

1. Laboratory diagnosis of urinary tract infection
2. Laboratory diagnosis of pyogenic meningitis
3. Etiology of fever of unknown origin (FUO)
4. Types of blood stream infections (BSI)
5. Laboratory diagnosis of diarrheal diseases
6. TORCH infections
7. Agents causing surgical site wound infection
8. Laboratory diagnosis of respiratory tract infections

CHAPTER 55

Hospital Acquired Infections

Chapter Preview

- Hospital acquired infections
- Prevention of Hospital acquired infections
- Hospital infection control committee

HOSPITAL ACQUIRED INFECTIONS (HAIs)

Definition

Hospital acquired infections or nosocomial infections or healthcare-associated infections (HAIs) can be defined as the infections acquired in the hospital by a patient:

- Who was admitted for a reason other than that infection
- In whom the infection was not present or incubating at the time of admission
- Symptoms should appear at least after 48 hours after admission
- This include infections acquired in the hospital but appearing after discharge, and also occupational infections among staff of the hospital care facility.

CDC (Centre for Disease Control and Prevention, Atlanta) had established the National Nosocomial Infections Surveillance (NNIS) programme to monitor the incidence of nosocomial infections.

It is estimated that 5–10% of patients admitted to acute care hospitals develop HAIs. Treatment of these HAIs adds a huge economic burden to the hospital.

Factors Affecting HAIs

The principal factors that determine the likelihood that a given patient would acquire a nosocomial infection are:

- **Immune status:** Most admitted patients have impaired immunity either as a part of their preexisting disease processes or, in some instances, due to the treatment they have received in the hospital.
- **Hospital environment**: The hospital environment harbors a greater magnitude of microorganisms than that of community. Transmission of these organisms to the patients can cause nosocomial outbreaks of infection.
- **Hospital organisms:** Most of the organisms present in the hospital environment are multidrug resistant. This is because of the increased antibiotic usage in the hospital. The minor population of resistant organisms present initially flourish in presence of constant antibiotic pressure and slowly replace the susceptible strains in the hospital.
- **Diagnostic or therapeutic interventions** such as insertion of intravenous or urinary catheters, or endotracheal tube, may introduce infection in susceptible patients; most of which are due to the patient's endogenous flora.
- **Transfusion:** Blood, blood products and intravenous fluids used for transfusion, if not properly screened, can transmit many blood borne infections (BBI) such as HIV, Hepatitis B and C viruses.
- **Poor hospital administration:** Strong administrative support is essential to control the HAIs; failing of which promote the spread of HAIs.

Sources of Infection

Endogenous Source

The majority of nosocomial infections are endogenous in origin, i.e. they involve patient's own microbial flora which may invade the patient's body during some surgical or instrumental manipulations.

Exogenous Source

Exogenous sources are from hospital environment, staff, or patients.

- **Environmental sources** include inanimate objects, air, water and food in the hospital. Inanimate objects in the hospital are medical equipments (endoscopes, catheters, etc.), bed pans, surfaces contaminated by patients' excretions, blood and body fluids.

- **Healthcare workers** may be potential carriers, harboring many organisms; which may be multidrug resistant, e.g. nasal carriers of Methicilin-resistant *Staphylococcus aureus* (MRSA).
- **Other patients** of the hospital may also be the source of infection

Microorganisms Implicated in HAIs

Hospital acquired infections can be caused by almost any microorganism, but those that survive in the hospital environment for long periods and develop resistance to antimicrobials and disinfectants are particularly important.

The ESKAPE pathogens: They are responsible for a substantial percentage of nosocomial infections in the modern era and represent the vast majority of multidrug resistant isolates present in a hospital.

- ***Enterococcus faecium***
- ***Staphylococcus aureus***
- ***Klebsiella pneumoniae***
- ***Acinetobacter baumannii***
- ***Pseudomonas aeruginosa***
- ***Enterobacter*** species

Other infections that can spread in hospitals include:

- *Escherichia coli*
- Nosocomially acquired *Mycobacterium tuberculosis*
- *Legionella pneumophila*
- *Candida albicans*
- *Clostridium difficile* diarrhea
- Blood borne infections transmitted through contaminated needle prick injury or mucocutaneous exposure of blood includes HIV, hepatitis B and C viral infections.

Modes of Transmission

Microorganisms spread in the hospital through several modes (Table 55.1).

Types of HAIs

In any hospital, the four most common HAIs encountered are:

- Urinary tract infections (UTIs) (33%)
- Pneumonia (15%)
- Surgical site infections (15%)
- Blood stream infections (13%)

In addition, there are some other infections which can also occur rarely in a hospital setting.

Urinary Tract Infections (UTIs)

Urinary tract infections account for the majority of HAIs.

- **Risk factors** that predispose patients to acquire a nosocomial UTI include—(1) advanced age, (2) female gender, (3) severe underlying disease, (4) placement of a urinary catheter.
- **Organisms:** Gram-negative rods cause the majority of hospital acquired UTIs and *E. coli* is the number one organism implicated. Gram-positive bacteria and *Candida* cause the remainder of the infections.

TABLE 55.1: Modes of transmission of hospital acquired pathogens

Route	Description
Contact transmission	
Direct contact	Skin to skin contact and thereby physical transfer of microorganisms between a susceptible host and an infected or colonized person (usually healthcare workers, rarely other patients) **This is the most important and frequent mode of transmission.**
Indirect contact	This involves contact of a susceptible host with contaminated inanimate objects such as: ▪ Dressings, or gloves, instruments (e.g. stethoscope) ▪ Parenteral transmission through: Needle or sharp prick injury, splashes of blood or body fluids or excretions, contaminated saline flush, syringes, vials and bags
Inhalational mode	
Droplet transmission	Droplets of >5 µm size can travel for shorter distance (<3 feet). ▪ Droplets generated from the infected person while coughing, sneezing and talking are propelled for a short distance through the air and deposited on the host's body. ▪ This is an important mode of transmission of agents causing bacterial meningitis, diphtheria, and RSV etc.
Airborne transmission	This refers to the airborne droplet nuclei (≤ 5 µm size) or dust particles that remain suspended in the air for long time and can travel longer distance. ▪ This is more efficient mode than droplet transmission. ▪ Microorganisms transmitted by airborne transmission include *Legionella, Mycobacterium tuberculosis,* measles and varicella-zoster viruses.
Vector borne transmission	
	▪ Via vectors such as mosquitoes, flies, etc carrying the microorganisms. ▪ This is a rare mode of transmission in hospital.
Common vehicle transmission	
	Such as food, water, devices and equipments

Pneumonia

Lung infections are the major cause of HAIs after UTI.

- **Risk factors** to develop nosocomial pneumonia are (1) advanced age, (2) chronic lung disease, (3) aspiration of upper respiratory tract secretions into the lungs, (4) semiconscious patient, (5) chest surgeries (6) mechanical ventilation through intubation of endotracheal tube (ventilator-associated pneumonia)
- **Organisms:** Gram-negative rods and *S. aureus*, account for majority of infections of the patients from the hospital.

Surgical Site Infections

Surgical site infections (SSI) are defined as infections that develop at the surgical site within 30 days of the surgery.

- Though SSI is a major threat in the hospitals, it is often under reported because a substantial proportion (50%) of SSIs develop after discharge of the patients from the hospital.
- **Organisms:** Surgical site wounds are classified as clean, clean-contaminated, contaminated or dirty.
  - **For clean wound:** The skin flora of the surgery team or the environmental organisms are the major pathogens; most common being *S. aureus*.
  - **For other types:** The patient's endogenous flora (anaerobes and gram-negative rods) are the common agents.
- **Risk factors** for nosocomial wound infection include:
  - Advanced age, obesity, malnutrition, diabetes, etc
  - Infections at a remote site that spread through blood stream
  - Time interval between pre-operative shaving of the site and the surgery—if exceeds more than 12 hours
  - Inappropriate timing of prophylactic antimicrobial agent

Note: The antimicrobial prophylaxis is usually given to the patient to prevent the seeding of organisms on the surgical site. It is given 1 hour prior to the incision, usually along with the induction of anesthesia.

Blood Stream Infections

Nosocomial blood stream infections are the fourth common cause of HAIs.

- **Organisms:** Coagulase negative staphylococci, *S. aureus* and enterococci are increasingly reported recently followed by gram-negative rods and *Candida*.
- **Risk factors** that predispose the patients to acquire a nosocomial bloodstream infection include:
  - Age (<1 years and >60 years), and malnutrition
  - Low immunity or severe underlying disease
  - Loss of skin integrity (burn or bed sore)
  - Prolonged hospital stay, especially in ICUs
  - Presence of intravascular catheters

PREVENTION OF HAIs

Standard (Routine) Precautions

Standard precautions are a set of infection control practices (see box below) used to prevent transmission of diseases that can be acquired by contact with blood, body fluids, non-intact skin (including rashes), and mucous membranes. These measures should be followed when providing care to:

- All individuals, whether or not they appear infectious/symptomatic or not.
- All specimens (blood or body fluids) whether they appear infectious or not.
- All needles and sharps whether they appear infectious or not.

Note: Universal precautions was a term used in the past to refer to the infection control practices to avoid contact with patients' body fluids, by means of wearing the nonporous articles such as medical gloves, goggles, and face shields. Now it is replaced by the word "standard precaution" which in addition include the measures to prevent contact (i.e. skin and mucosal) transmission.

Standard Precautions

They are indicated while handling all patients, specimens and sharps. Components of standard precautions include:

- **Hand hygiene:** (details explained later)
  - Wash hands promptly after contact with infective material
  - Use no touch technique wherever possible
- **Personal protective equipments** (PPEs):
  - Wear gloves when expecting contact with blood, body fluids, secretions, excretions, mucous membranes and contaminated items and wash hands immediately after removing gloves.

Standard Precautions

They are indicated while handling all patients, specimens and sharps. Components of standard precautions include:

- **Hand hygiene:** (details explained later)
  - Wash hands promptly after contact with infective material
  - Use no touch technique wherever possible
- **Personal protective equipments** (PPEs):
  - Wear gloves when expecting contact with blood, body fluids, secretions, excretions, mucous membranes and contaminated items and wash hands immediately after removing gloves.
  - Wear other PPE such as mask, gown, shoes, eye cover, etc whenever indicated.
- **Sharp handling:** All sharps should be handled with extreme care
- **Spillage cleaning:** Clean up spills of infective material promptly
- **Disinfection:** Ensure that patient-care equipment, supplies and linen contaminated with infective material are either discarded, or sterilized between each patient use.
- **Waste handling:** Ensure appropriate biomedical waste seggregation and disposal (as described in chapter 56)

Specific Precautions

Additional precautions are needed for preventing specific modes of transmission.

Airborne Precautions

The following measures are required:

- Individual room should be provided with adequate ventilation with negative pressure facility.
- Staff should wear high-efficiency masks in room
- Patient should be confined to the room.

Droplet Precautions

The following procedures are required:

- Individual room for the patient, if available
- Mask for healthcare workers
- Restricted movement of the patient; patient wears a surgical mask while leaving the room.

Contact Precautions

These are required for patients with enteric infections and diarrhea which cannot be controlled, or skin lesions which cannot be contained.

- Individual room for the patient if available; cohorting of patients if possible
- Staff should wear gloves and gowns on entering the room.
- Hand washing should be done before and after contact with the patient, and on leaving the room.
- Appropriate environmental and equipment cleaning, disinfection, and sterilization to be followed.

Precautions for Patients with MDROs

The increased occurrence of multidrug resistant organisms (MDROs) is a major medical concern. The spread of MDROs such as multidrug resistant MRSA is usually by transient carriage on the hands of healthcare workers.

The following precautions are required for the prevention of spread of epidemic of MRSA:

- Minimize ward transfers of staff and patients
- Ensure early detection of cases, especially if admitted from another hospital; screening of high risk patients may be considered
- Isolate infected or colonized patients in a single room, isolation unit or cohorting in a larger ward
- Reinforce hand washing by staff after contact with infected or colonized patients
- Use gloves, gown or apron for handling MRSA-contaminated materials, or infected or colonized patients
- Consider treating nasal carriers with mupirocin
- Consider daily wash or bath by antiseptic detergents for carriers or infected patients
- Ensure careful handling and disposal of medical devices, linen, waste, etc.
- Develop guidelines specifying when isolation measures can be discontinued.

Hand Hygiene

Hands are the main source of transmission of infections during healthcare. Hand hygiene is therefore the most important measure to avoid the transmission of harmful microbes and prevent healthcare-associated infections.

Any healthcare worker involved in direct or indirect patient care needs to be concerned about hand hygiene and should be able to perform it correctly and at the right time.

Types of Hand Hygiene Methods

Hand Rub

Alcohol based (70–80% ethyl alcohol) and chlorhexidine (2–4%) based hand rubs are available. The duration of contact has to be at least for 20–30 seconds.

- **Advantage:** After a period of contact, it gets evaporated of its own hence drying of hands is not required separately.
- **Indications:** Hand rub is indicated during routine rounds in the wards or ICUs; in all the moments or situations requiring hand hygiene, except when the hands are visibly dirty or soiled, when it will be ineffective.

Hand Wash

Antimicrobial soaps (liquid, gel or bars) are available. If facilities are not available, then even ordinary soap and water can also be used. The duration of contact has to be at least for 40–60 seconds. Hand washing is indicated in the following situations:

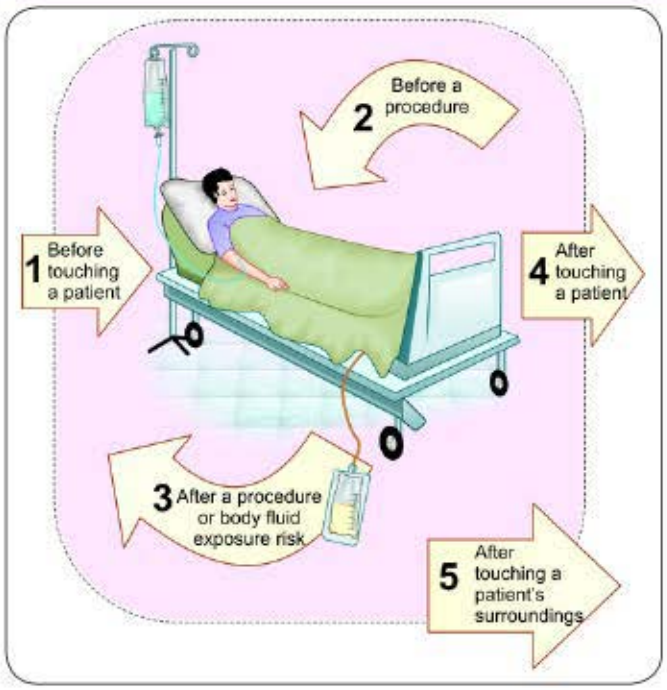
- When the hands are visibly soiled with blood, excreta, pus, etc.
- Before and after eating
- After going to toilet
- Before and after shift of the duty

Five Moments for Hand Hygiene

The World Health Organization (WHO) has published standard guidelines describing the situations or opportunities when hand hygiene is indicated in healthcare sectors. (Fig. 55.1)

Steps of Hand Rubbing and Hand Washing

WHO has also laid down the guidelines describing the appropriate steps involved for an effective hand rubbing and hand washing (Fig. 55.2)



1 Before touching a patient
2 Before a procedure
3 After a procedure or body fluid exposure risk
4 After touching a patient
5 After touching a patient's surroundings

Fig. 55.1: Five moments for hand hygiene

Source: WHO

HOSPITAL INFECTION CONTROL COMMITTEE

The hospital infection control programme is organized and run by the Medical Superintendent (MS), for which he/she constitutes the Hospital Infection Control Committee (HICC).

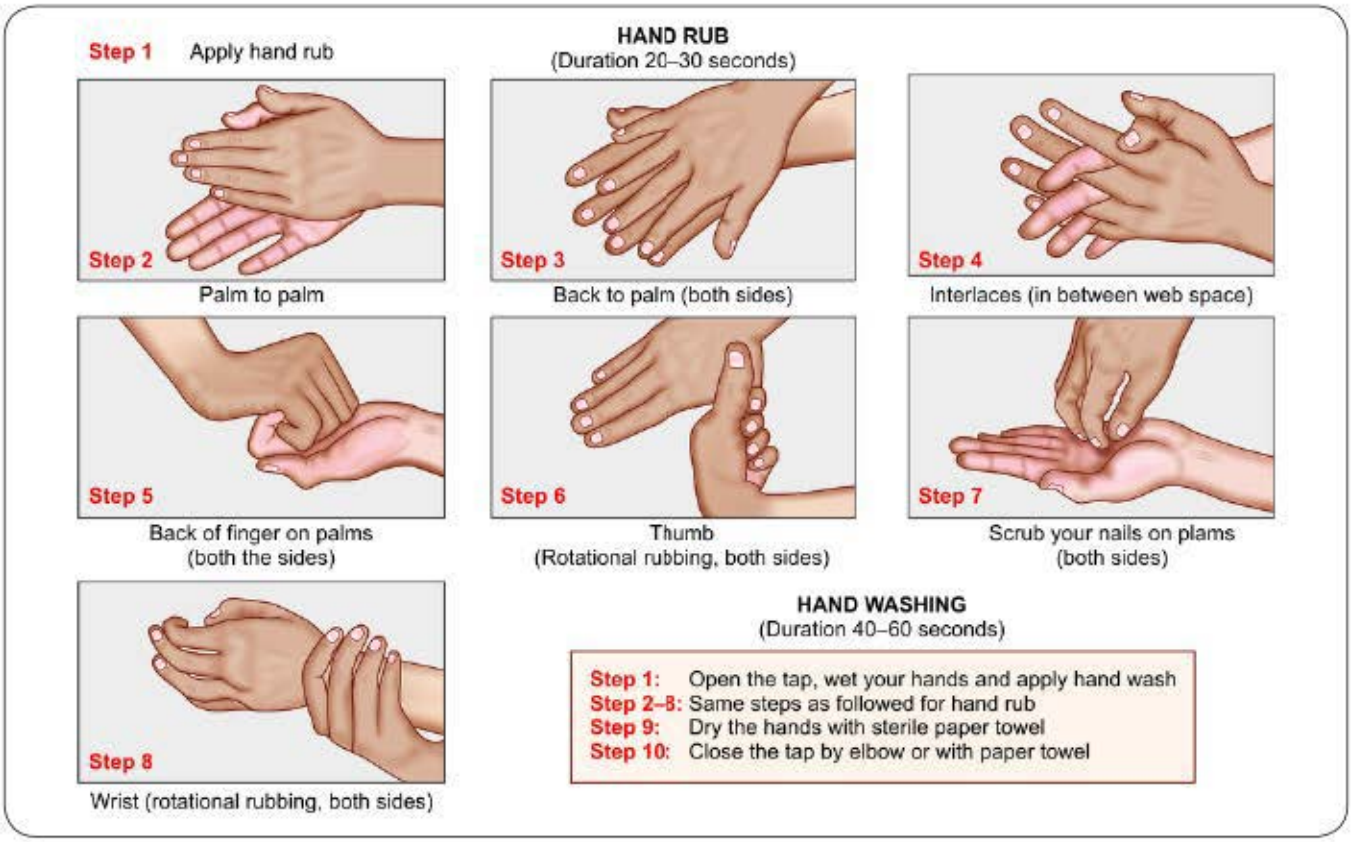
The HICC provides a forum for multidisciplinary input and cooperation, and information sharing, required for hospital infection control and prevention. The HICC is advisory to the MS and makes its recommendations to the MS.

HICC Constitution

The hospital infection control committee (HICC) should include wide representations from relevant departments/health sectors as follows:

- Chairperson, usually the Medical Superintendent
- Secretary, usually the head of department of microbiology
- Hospital Infection Control Officer (HICO), usually a representative from the department of microbiology
- Hospital Infection Control Nurses (HICN)
- Head of all the clinical (all medical and all surgical) departments

Contd...



HAND RUB
(Duration 20–30 seconds)
Step 1 Apply hand rub
Step 2
Palm to palm
Step 3
Back to palm (both sides)
Step 4
Interlaces (in between web space)
Step 5
Back of finger on palms (both the sides)
Step 6
Thumb (Rotational rubbing, both sides)
Step 7
Scrub your nails on plams (both sides)
Step 8
Wrist (rotational rubbing, both sides)
HAND WASHING
(Duration 40–60 seconds)
Step 1: Open the tap, wet your hands and apply hand wash
Step 2–8: Same steps as followed for hand rub
Step 9: Dry the hands with sterile paper towel
Step 10: Close the tap by elbow or with paper towel

Fig. 55.2: Steps of hand rubbing and hand washing (WHO)

Contd...

- Nursing Superintendent
- Head of the Staff clinic
- Operation Room Supervisor
- In-charge of Central Sterile Supplies Department (CSSD)
- In-charge of pharmacy
- In-charge of hospital linen
- In-charge of hospital laundry
- In-charge of hospital kitchen
- Epidemiologist
- In-charge of engineering department of hospital

Terms of Reference of HICC

The HICC supervises the implementation of the hospital infection control programme. The various functions of the committee include:

- **HAI surveillance:** Maintains surveillance of hospital acquired infections. The four key parameters used for HAI surveillance are as follows:
  1. CA-UTI (Catheter associated urinary tract infection)
  2. CLABSI (Central line associated bloodstream infection)
  3. VAP (Ventilator associated pneumonia)
  4. SSI (Surgical site infections)
- **Develops a system** for identifying, reporting, analyzing, investigating and controlling hospital acquired infections.
- **Antibiotics usage:** Develops antibiotic policies, monitors the antibiotic usage, advices the MS on matters related to the proper use of antibiotics, and also recommends remedial measures when antibiotic resistant strains are detected.
- **Policies:** Reviews and updates hospital infection control policies and procedures from time to time.
- **Education:** Conducts teaching sessions for healthcare workers regarding matters related to HAIs.
- **Staff health:** Monitors employee health activities regarding matters related to HAIs such as needle stick injury prevention, hepatitis B vaccination, etc.
- **Outbreak management:** Develops strategies to identify infectious outbreaks, their source and implements preventive and corrective measures.
- **Other departments:** Communicates and cooperates with other departments of the hospital with common interests such as:
  - Pharmacy
  - Central Sterile Supplies department (CSSD)
  - Linen and laundry department(s)
  - Antimicrobial Usage Committee
  - Biomedical Safety Committee
  - Blood Transfusion Committee
- **Reviews** risks associated with new technologies, and monitor infectious risks of new devices and products, prior to their approval for use.
- **HICC Meetings:** Shall meet meet regularly not less than once a month and as often as required. However, in an emergency (such as an outbreak), this committee must be able to meet promptly.

EXPECTED QUESTIONS

I. Write short notes on:

1. Modes of transmission of hospital acquired pathogens
2. Prevention of healthcare associated infections
3. Hospital infection control committee (HICC)
4. Hand hygiene
5. Standard (routine) precautions

II. Multiple Choice Questions (MCQs):

1. Which parameter is not included in HAI surveillance?
   a. CA-UTI (catheter associated urinary tract infection)
   b. CLABSI (central line associated bloodstream infection)
   c. VAP (ventilator associated pneumonia)
   d. Open wound infections

2. Hand rub should not be used in which condition?
   a. Before touching patient
   b. After touching patient
   c. After touching patient's surrounding
   d. Hands are visibly soiled

3. How many moments of hand hygiene have been laid down by WHO?
   a. 5
   b. 6
   c. 7
   d. 8

Answer
1. d **2.** d **3.** a

CHAPTER 56

Biomedical Waste Management

Chapter Preview

- Categories of Biomedical Waste
- Treatment and Disposal Methods
- Waste Segregation in Hospitals
- Biomedical Waste Rules 2011

The waste generated from the healthcare facilities carries a higher potential for infections and injuries. Therefore, it is essential to have safe and reliable methods of segregation and disposal of hospital waste.

CATEGORIES OF BIOMEDICAL WASTE

Definition

According to Bio-Medical Waste Rules, 1998 of India, "Biomedical waste" means any waste, which is generated during the diagnosis, treatment or immunization of human beings or animals or in research activities pertaining there to or in the production or testing of biologicals and including categories mentioned in Schedule I (Table 56.1).

Waste Generated in Hospitals

It is estimated that quantity of solid waste generated in hospitals varies from 1/2 to 2 kg/bed in Government hospitals, private hospitals and nursing homes. However, biomedical waste accounts for a minor proportion of total waste generated in hospitals.

In developing countries, the waste generated in hospitals falls into the following categories:

- **General waste (80%):** Vast majority of waste falls in the general waste category, which may be disposed with the usual domestic and urban waste management system. They do not cause any harm to humans.
- **Pathological and infectious waste (15%):** This is the component of hospital waste that produces maximum hazards. Pathogens in the infectious waste may infect health care workers by entering through ingestion, inhalation or direct skin to skin contact.
- **Chemical and pharmaceutical waste (3%):** Most of the chemicals (e.g. disinfectants) and pharmaceuticals waste are toxic , genotoxic (affect genetic system), corrosive, flammable, explosive or shock sensitive.
- **Sharp waste (1%):** Needle sticks and other sharps are of great concern as they are capable of transmitting blood borne pathogens such as HIV, hepatitis B and C virus, etc.
- Less than 1% accounts for special waste such as cytotoxic drug, radioactive waste, broken thermometers and used batteries.

Situation in India

According to the Ministry of Environment and Forests (MoEF), gross generation of biomedical waste in India is about 4,05,702 kg/day, of which only 2,91,983 kg/day is properly disposed, which means that almost 28% of the wastes is left untreated and not disposed, finding its way in dumps or water bodies and re-enters our system. Karnataka tops the chart among all the states in generation of biomedical waste.

TREATMENT AND DISPOSAL METHODS

There are several methods of disposal of biomedical waste. Though incineration is widely used, the recently developed alternative methods are becoming increasingly popular.

Incineration

It has been the method of choice of disposal of biomedical waste.

- Incineration is a high temperature dry oxidation process that reduces organic and combustible waste into nonorganic incombustible matter, resulting in a very significant reduction of waste volume and weight.
- Incineration is usually done for those wastes that cannot be reused, recycled or disposed off in a land fill site, for example human and animal anatomical waste, microbiological waste, solid non-plastic infectious waste.
- Incineration should not be done for:
  - Pressurized gas containers

TABLE 56.1: Categories of biomedical waste (Schedule I)

Categories	Waste Category	Treatment and Disposal
Category No 1	**Human anatomical waste** (human tissues, organs and body parts)	Incineration*/deep burial**
Category No 2	**Animal waste** (animal tissues, organs, body parts carcasses, bleeding parts, fluid, blood and experimental animals used in research, waste generated by veterinary hospitals/ colleges, discharge from hospitals, animal houses)	Incineration*/deep burial**
Category No 3	**Microbiology and biotechnology waste** (wastes from laboratory cultures, stocks or specimens of micro-organisms, live or attenuated vaccines, human and animal cell culture used in research and infectious agents from research and industrial laboratories, wastes from production of biological, toxins, petri dishes and devices used for transfer of cultures)	Local autoclaving/ microwaving/incineration*
Category No 4	**Waste sharps** (needles, syringes, scalpels, blades, glass, etc that may cause puncture and cuts. This includes both used and unused sharps)	Disinfection (chemical treatment*/ autoclaving/ microwaving) and mutilation/ shredding
Category No 5	**Discarded medicines and cytotoxic drugs** (wastes comprising of outdated contaminated and discarded medicines)	Incineration/destruction/disposal in secured landfills
Category No 6	**Solid waste** (items contaminated with blood and body fluids including cotton, dressings, soiled plaster casts, line beddings, other material contaminated with blood)	Incineration*/autoclaving/microwaving
Category No 7	**Solid waste** (disposable items other than the waste sharps such as tubing, catheters, intravenous sets, etc.)	Disinfection by chemical treatment#/ autoclaving/ microwaving and mutilation/ shredding##
Category No 8	**Liquid waste** (waste generated from laboratory and washing, cleaning, house-keeping and disinfecting activities)	Disinfection by chemical treatment# and discharge into drains
Category No 9	**Incineration ash** (ash from incineration of any biomedical waste)	Disposal in municipal landfill
Category No 10	**Chemical waste** (chemicals used in production of biological, chemicals, used in disinfection, as insecticides, etc)	Chemical treatment# and discharge into drains for liquids and secured landfill for solids

*There will be no chemical pretreatment before incineration. Chlorinated plastics shall not be incinerated.

**Deep burial shall be an option available only in towns with population less than five lakhs and in rural areas.

#Chemicals treatment using at least 1% hypochlorite solution or any other equivalent chemical reagent. It must be ensured that chemical treatment ensures disinfection.

##Mutilation/shredding must be such so as to prevent unauthorized reuse.

- Reactive chemical waste
- Halogenated plastics such as PVC (polyvinyl chloride)
- Waste with heavy metals such as mercury, silver salts, radiographic waste, broken thermometers

Autoclave

Autoclaving is a thermal process where steam is brought into direct contact with waste in a controlled manner and for sufficient duration to sterilize the wastes. For ease and safety in operation, the system should be horizontal type and exclusively designed for the treatment of biomedical waste. For optimum results, prevacuum based system is preferred against the gravity type system. It shall have tamper-proof control panel with efficient display and recording devices for critical parameters such as time, temperature, pressure, date and batch number, etc.

Chemical Disinfection

Chemicals are added to waste to kill or inactivate the pathogens within it. It results in disinfection rather than sterilization.

- It is more suitable for liquid waste such as blood, urine, stool and hospital sewage.
- However, solid waste, such as microbiological cultures and sharps, etc may be disinfected chemically with certain limitations.

Effluent Treatment Plant

The liquid effluent generated during the process of washing containers, vehicles, floors, etc is first subjected to chemical treatment and then disposed in effluent treatment plant.

Microwaving

In microwaving, microbial inactivation occurs as a result of the thermal effect of electromagnetic radiation spectrum lying between the frequencies 300 and 300,000 MHz.

- It is an inter-molecular heating process.
- The heating occurs inside the waste material in the presence of steam.
- The efficacy of microwave disinfection should be monitored regularly.

Shredder

Shredding is a process by which waste are deshaped or cut into smaller pieces so as to make the wastes unrecognizable. It helps in prevention of reuse of biomedical waste and also acts as identifier that the waste has been disinfected and is safe to dispose off.

Sanitary Land Fill

It is a small deep burial pit of 2 meters depth. It should be half filled with waste, then covered with lime within 50 cm of the surface, before filling the rest of the pit with soil. It is specially designed for disposal of hospital waste.

- For health and safety, a landfill site should be constructed away from residency, forests and coastal waters.
- If the facilities are not available to treat the waste before disposal, landfills are regarded as an acceptable route of disposal. However, medical waste should not be disposed in open dump.
- The wastes falling under category 5, i.e. discarded medicines, cytotoxic drugs and category 10, i.e. chemical wastes (solids) can be disposed in a secured landfill.

WASTE SEGREGATION IN HOSPITALS

Waste segregation refers to the basic separation of different categories of waste generated at source in the hospital and thereby reducing the risks as well as cost of handling and disposal. Segregation is the most crucial step in biomedical waste management.

According to Bio-Medical Waste Rule (1998), segregation should be done by using containers of four different colors, each is designated for segregation of a particular waste category (Table 56.2).

- Most of the containers are made up of plastic bags; except for the sharp containers which should be made up of puncture proof boxes.
- Plastic bags must be labelled with biohazard logos (Fig. 56.1) and should be inflammable and non-chlorinated.

TABLE 56.2: Color coding and type of container used for disposal of biomedical waste (Schedule II)

Color Coding	Waste Category	Treatment Options
Yellow (plastic bag)	1,2,3,6	Incineration/deep burial
Red (plastic bag)	3,6,7	Autoclaving/Microwaving/ Chemical Treatment
Blue/white (puncture proof)	4,7	Autoclaving/Microwaving/ chemical treatment and destruction/shredding
Black (plastic bag)	5,9,10	Disposal in secured land fill

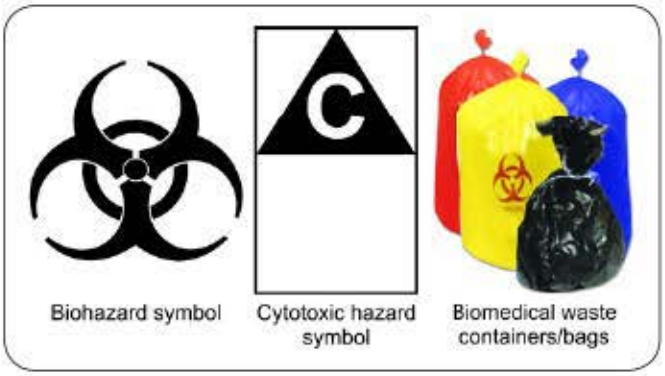


Fig. 56.1: Logos and color-coded plastic bags used for segregation of biomedical waste

BIOMEDICAL WASTE RULES 2011 (DRAFT)

The Ministry of Environment and Forests (MoEF) had proposed a revised draft of Bio-Medical Waste Rules 2011. It is much simpler, containing **8 categories** of wastes, each has to be segregated by a single color bag, thus clears the confusion over the color coding of the containers used for disposal of biomedical waste under 1998 Rule. However, this new rule has not been enforced yet. It is still under consideration.

EXPECTED QUESTIONS

I. Write short notes on:

1. Categories of biomedical waste
2. Disposal methods available for biomedical waste
3. Type of container used for disposal of biomedical waste

CHAPTER 57

Bacteriology of Water, Milk, Air and Food

Chapter Preview

- Bacteriology of water
- Bacteriology of milk
- Bacteriology of air
- Bacteriology of food

BACTERIOLOGY OF WATER

"**Wholesome water**" refers to the water that is fit to use for drinking, cooking, food preparation or washing without any potential danger to human health. Drinking water should have the following three properties to be lablled as 'wholesome water.'

- **Biological quality:** It should be free from potentially pathogenic microorganisms
- **Chemical quality:** It should be free from harmful chemical substances such as metals, solvents, pesticides and hydrocarbons
- **Physical quality:** It should have pleasant taste, color and odor.

As a part of public health program, drinking water supplies should be regularly tested for microbiological, chemical and physical quality. Discussion in this chapter is confined to the bacteriological quality assessment of water.

Bacterial Flora in Water

Bacterial flora present in water may be of various types (Table 57.1).

Naturally occurring water bacteria, soil bacteria and sewage bacteria usually arise from decomposing organic matter and are not pathogenic to humans. Their presence in water does not warrant threat. It is the sewage intestinal bacteria which are of major concern to humans and their presence in water supplies has to be monitored regularly.

Supplies of drinking water contaminated with sewage and other excreted products may cause life-threatening water borne diseases such as typhoid, cholera, polio, viral hepatitis A and E, etc (Table 57.2). Hence, drinking water supplies should be regularly tested to confirm that they are free from such contamination.

- However, it is impracticable to attempt directly to detect the presence of all the different kinds of water borne pathogens because they are usually present in minute quantity and intermittently.
- Instead, it is wise to test the water supplies for those microorganisms which indicate that fecal contamination has taken place. These organisms are called **indicator organisms**. (Table 57.3)

Indicator Organisms

Indicator organisms are usually the commensal bacteria of intestine which satisfy two properties:

1. They should be present in excess number than any pathogen so that they can be detected easily; at the

TABLE 57.1: Bacterial flora in water

Natural water bacteria	
Includes those organisms that are commonly found in water, free from gross pollution	▪ *Micrococcus* ▪ *Pseudomonas* ▪ *Serratia* ▪ *Flavobacterium* ▪ *Alcaligenes* ▪ *Acinetobacter*
Soil bacteria	
These organisms are frequently washed into the water during heavy rains and are not normal inhabitants of water	▪ *Bacillus subtilis* ▪ *Bacillus megaterium* ▪ *Enterobacter aerogenes* ▪ *Enterobacter cloacae*
Sewage bacteria	
These include: ▪ Majority are the normal inhabitants of the intestine of man and animals. ▪ Other sewage bacteria are the bacteria that live mainly on decomposing organic matter	**Intestinal bacteria** (through sewage): *Escherichia coli, Enterococcus faecalis, Clostridium perfringens, Salmonella, Vibrio cholerae* **Other sewage bacteria:** *Proteus,* *Clostridium sporogenes* and others

TABLE 57.3: Indicator organisms of fecal contamination of water

Indicator organisms	Interpretation (Presence in water indicates)
Coliform (other than *E. coli*)	Remote contamination with either fecal (presumptive) or soil and vegetation
Fecal (thermotolerant) *E. coli*	▪ Confirms recent fecal contamination of water ▪ Most sensitive indicator
Fecal streptococci	Confirms remote fecal pollution
Clostridium perfringens	Remote contamination
Pseudomonas aeruginosa	▪ Least reliable indicator ▪ Useful in hospitals and food establishments
Bacteriophages	▪ Phage specific for *E. coli*- indicate fecal pollution of water ▪ Indirectly indicates viral pollution of water

same time, they should not be able to proliferate in water to any extent.

2. They should be more resistant than the pathogens to the stresses of aquatic environment and disinfection processes.

Indicator organisms themselves are not pathogens. But their presence in water supplies indicates that there is a contamination of sewage and the water supplies needs to be disinfected. However, it is also to be kept in mind that mere presence of these indicator organisms does not assure the presence of water borne pathogens.

There are a number of intestinal commensals used as indicator organisms, described below.

Coliform (Presumptive Coliform)

They are the members of Enterobacteriaceae that are present in large numbers in sewage.

- Among them, only *Escherichia coli* is a reliable indicator as it is not found in other sources.
- However other coliforms such as *Klebsiella, Citrobacter, Enterobacter*, etc. are much less abundant in feces than *E. coli*, and survive for longer time than *E. coli*.
  - They are also found in the environment as saprophytes.
  - Therefore, their presence in water may indicate either remote fecal pollution of water (long enough to have allowed *E. coli* to die out) or contamination from soil and vegetations.

Fecal Escherichia coli

It is regarded as the essential indicator of pollution of water with feces of human or animal origin.

- It is defined as the thermotolerant coliform organism that—(1) ferments lactose at 44°C with production of acid and gas and (2) gives a positive indole test at 44°C.
- Fecal *E. coli* is the most numerous coliform in humans and animal intestine and is derived almost exclusively from these sources.
- It does not survive in water for long time, and therefore is the **best indicator** of recent human or animal fecal pollution of water.
- Its presence in water indicates a potentially dangerous fecal pollution of water.

Fecal Streptococci

These are the commensals of intestine belonging to Group D streptococci.

- They are less abundant in feces than *E. coli*, can survive longer in water than *E. coli*. Hence their presence along with coliforms, despite absence of *E. coli* confirms fecal pollution of water.
- Fecal streptococci can be either enterococci or non-enterococcal streptococci. Most of the species are abundant in animal feces, except *Enterococcus faecalis* which is abundant in human feces.

Sulphite Reducing Clostridia (C.perfringens)

These reduce sulphite to sulphide.

- Though *Clostridium perfringens* is less numerous in human feces (least sensitive indicator), their spores can survive for longer time in the environment.
- Their presence indicates remote or intermittent fecal pollution of water.

Pseudomonas aeruginosa

Though it can survive in the environment for long time, it can multiply in various aquatic habitats. Hence, its presence in water is not necessarily good indicator of fecal contamination.

- However, it is frequently encountered in hospital environment and a cause of food spoilage.
- So, its detection in water supplies of hospitals and food establishments indicates fecal pollution.

Bacteriophages

The phages that infect *E. coli* can be used as indicator of fecal pollution of water. They may also be used as indicator of viral pollution as their occurrence and resistance in the environment and to chlorine is similar to that of enteroviruses.

Bacteriological Examination of Water

Collection and Transport of Water Sample

Heat sterilized screw capped bottles (at least 200 ml holding capacity) should be used for collection of water. Extreme care should be taken to avoid contamination of the bottle with the bacteria present in the surrounding environment or hands of the collecting person. At least 150 mL of water should be collected.

- Sodium thiosulfate is added to neutralize the bactericidal effect of residual chlorine present in water if any.
- **Water from tap:** Water should be collected only after running it from the tap for 2-3 minutes.
- **Water from streams or lakes:** The bottle should be opened only after immersed at a depth of 30 cm with its mouth facing the current.
- **Water from well:** It is collected by bottles tied with heavy weight (stones).
- **Transport:** The bottle should be properly labeled and sent to the laboratory as quickly as possible at least within 6 hours. If delay is anticipated, the bottles should be kept in an ice box and protected from light.

Methods of Analysis

The standard tests usually employed for bacteriological analysis of water are, (1) Presumptive coliform count, (2) Differential coliform count.

Presumptive Coliform Count (Multiple Tube Method)

Multiple tube method is used for the estimation of presumptive coliform count, which is expressed as the most probable number (MPN) of coliform organisms in 100 mL of water.

- **Medium:** MacConkey purple broth (double strength and single strength) in bottles or tubes is the standard medium of choice.
  - Durham's tube is used to detect gas production.
  - Bromocresol purple is used as indicator.
- **Procedure:** Measured amount of water samples are added to tubes containing MacConkey purple broth by sterile graduated pipettes as under:
  - 50 mL of water—added to one bottle of 50 mL double strength medium.
  - 10 mL of water each—added to 5 tubes of 10 mL double strength medium.
  - 1 mL of water each—added to 5 tubes of 5 mL single strength medium.
- **Result:** The inoculated tubes are incubated at 37° C for 48 hours. Positive test is indicated by (1) a color change in the medium from purple to yellow (due to lactose fermentation) and (2) gas collected in the Durham's tube.
- **Interpretation:** The interpretation of presumptive coliform count is as follows:
  - **Presumptive coliform count** (Most probable number): An estimate of coliform count per 100 mL of water is calculated from the tubes showing acid and gas production using the McCrady's probability table (Table 57.4).
  - **Quality of water supply** is determined by the presumptive coliform count. The most probable numbers of 0, 1–3, 4–9 and ≥10 per 100 mL are interpreted as excellent, satisfactory, intermediate and unsatisfactory respectively (Table 57.5).
  - Detection of coliform bacteria does not always indicate fecal contamination; as some of them may be found in environment. Hence, it is further tested by differential coliform count to detect the fecal *E. coli*.

Differential Coliform Count (Eijkman Test)

The Eijkman test is done to confirm that the coliform bacilli detected in the presumptive test are fecal *E. coli*. This is done by:

- Sub culturing the positive tubes (of the previously done presumptive coliform test) on lactose containing medium such as brilliant green bile broth for detection of lactose fermentation with production of acid and gas at 44°C and.
- Demonstrating positive indole test at 44°C.

Fecal Streptococci Detection

When presumptive coliforms are present but fecal *E. coli* are absent, detection of fecal streptococci would confirm the fecal origin of coliform bacilli.

TABLE 57.4: McCrady's probability table for calculating most probable number (MPN)/100 mL of water

Number of tubes giving a positive reaction out of

TABLE 57.5: Classification of quality of drinking water supply according to bacteriological tests

Quality of drinking water supply	Most probable number (MPN)/100 mL of water	
	Coliform counts/100 mL	*E. coli* count/100 mL
Excellent	0	0
Satisfactory	1–3	0
Intermediate	4–9	0
Unsatisfactory	≥10	≥1

- Subcultures are made from positive tubes obtained from the presumptive coliform test into tubes containing 5 mL of glucose azide broth and incubated at 45°C for 48 hours. Presence of acid in the medium indicates fecal streptococci.
- Further confirmation can be done by plating onto bile esculin azide agar (black colonies formed).
- Speciation can be done to know the exact source of fecal contamination—*Streptococcus bovis* (cow), *Streptococcus equinus* (horse), *Enterococcus avium* (birds), *Enterococcus faecalis* (humans).

Clostridium Perfringens Detection

Spores of *Clostridium perfringens* are detected by first heating the water sample (which kills all vegetative bacteria retaining the spores) and then performing multiple tube method by sub culturing it onto special medium called differential reinforced clostridial medium (DRCM).

Enzyme Methods

The detection of specific enzymes for the detection and confirmation of coliform bacilli and fecal *E. coli* is rapid and novel method described recently.

- β **galactosidase** is a coliform bacilli specific enzyme.
- β **glucuronidase** is a fecal *E. coli* specific enzyme.

Membrane Filtration Method

In this method, a measured volume of the water sample is filtered through a membrane of pore size small enough to retain the indicator bacteria to be counted on its surface.

- The membrane is then placed on a suitable selective indicator medium and incubated, so that the indicator bacteria grow as colonies on its upper surface.
- The bacterial content of the water is calculated by counting the total number of colonies grown.

Examination for Specific Water Borne Pathogens

Specific water borne pathogens may be isolated from water by employing enrichment and selective media.

- **For isolation of *Salmonella* Typhi:** Equal volume of water is added to the double strength selenite broth followed by incubation and then subcultured onto selective medium.
- **For *Vibrio cholerae*:** Water sample is mixed with alkaline peptone water in 1:9 ratio, incubated and subcultured onto selective medium. Isolated organisms are identified by biochemical tests and serotyping.
- Pathogenic organisms may also be isolated by membrane filtration method as described earlier.

BACTERIOLOGY OF MILK

Milk can occasionally contain bacteria which are derived from three sources:

1. From animals (fecal contamination or through infected udder, teat canals and skin)
2. From hands of the milk handlers
3. From the environment

The milk borne pathogens (Table 57.6) pose a threat to the community. They can be classified as follows:

- Agents primarily of animal origin that can be transmitted to man by milk.
- Agents primarily of human origin that can be transmitted by milk.

Methods used for Disinfecting/Sterilizing Milk

In general, there are four methods by which milk is sterilized or disinfected.

TABLE 57.6: Milk borne diseases (By Joint FAO/WHO Expert committee on Milk Hygiene, 1970)

Diseases primarily of animal origin that can be transmitted to man by milk	
Primary Importance	**Lesser Importance**
▪ Tuberculosis (*M. bovis*) ▪ Brucellosis ▪ Salmonellosis ▪ *Coxiella bumetii* (Q fever) ▪ Staphylococcal food poisoning ▪ Streptococcal infections	▪ Cow Pox ▪ Hand Foot Mouth Disease ▪ Anthrax ▪ Leptospirosis ▪ *Campylobacter jejuni* infection ▪ Tick borne encephalitis viruses
Diseases primarily of human origin that can be transmitted by milk	
Primary Importance	**Lesser Importance**
▪ Typhoid and paratyphoid fever ▪ Shigellosis ▪ Cholera ▪ Enterohemorrhagic *E. coli* (EHEC) infection	Non diarrheal diseases: ▪ Streptococcal infection ▪ Staphylococcal food poisoning ▪ Diphtheria ▪ Tuberculosis ▪ Enteroviral infections ▪ Viral hepatitis

1. **Thermized milk:** It is raw milk that has been heated for 15 seconds at 57–68°C. The efficacy of this process is tested by methylene blue reduction test.
2. **Pasteurization:** Milk is heated to high temperature for short time (72°C for 15 seconds). Bacterial spores, *Coxiella, Mycobacterium* and some preformed bacterial or fungal toxins are not destroyed effectively by pasteurization. Efficacy of pasteurization is tested by the phosphatase test.
3. **Ultra heat treated milk:** The milk is exposed to very high temperature of 135°C for 1 second so that all microorganisms with their spores are destroyed. It should pass the viable colony count test, i.e. have a viable colony count of less than 1000/mL after incubating on yeast extract milk agar for 48 hours.
4. **Sterilized milk:** The milk is heated at 100°C for long periods such that it can pass the turbidity test.

Methods for Bacteriological Examination of Milk

This is carried out by several methods:

- Colony count
  - Viable count
  - Coliform count
- Chemical tests
  - Methylene blue reduction test
  - Phosphatase test
  - Turbidity test
- Detection of specific pathogens

Colony Count Methods

Viable Count

This is done by plate dilution method. Serial dilutions of milk sample are incorporated in yeast extract milk agar.

- Then, it is incubated at 30°C or 21°C (for unopened container) for 72 hours.
- Number of colonies multiplied by dilution factor gives the colony count in the fixed amount of milk.
- Ultra heat treated milk should have a viable colony count of less than 1000/mL of milk.

Coliform Count

Serial dilutions of milk are inoculated into three tubes of MacConkey's broth with inverted Durham's tube and incubated at 37°C for 48 hours.

- The production of acid and gas is the evidence of presence of coliform bacilli.
- All coliforms are killed by pasteurization.
- The presence of coliform bacilli in pasteurized milk indicates improper pasteurization or post-pasteurization contamination.

Chemical Tests

Methylene Blue Reduction Test

This test is more economical than the viable count test.

- **Principle:** Viable bacteria reduce the methylene blue in milk when kept in a dark place.
- **Procedure:** The test is performed by mixing 1 ml of methylene blue solution to 10 ml of milk in a test tube. The tube is incubated in dark at 37°C.
- **Result:** The milk is considered satisfactory if it fails to decolorize methylene blue in 30 minutes.

Phosphatase Test

This test is done to test the effectiveness of pasteurization.

- **Principle:** Effective pasteurization should inactivate the enzyme alkaline phosphatase which is normally present in milk. Phosphatase enzyme breaks phenyl disodium phosphate to release phenol.
- **Procedure:** Presence of phosphatase enzyme in pasteurized milk is detected by adding buffer containing phenyl disodium phosphate to milk. A color development buffer is added and then the tube is incubated in water bath at 37°C for 2 hours.
- **Result:** A change in the color of the medium occurs if milk contains phosphatase releasing phenol. The phenol released is quantitated by measuring the absorbance of the color developed by a spectrophotometer.

Turbidity Test

This is a definitive test for checking the sterilization of milk.

- **Principle:** In boiled milk all heat coagulable proteins are precipitated so that it does not become turbid when ammonium sulphate is added.
- **Procedure:** Milk is heated to at least 100°C for 5 minutes and then ammonium sulphate is added.
- **Result:** Absence of turbidity indicates that the milk has been boiled or heated to at least 100° C for 5 minutes.

Detection of Specific Pathogens

- **Tubercle bacilli:** Following centrifugation of the milk (at 3,000 rpm for 30 minutes), the deposit is inoculated on Lowenstein-Jensen medium or injected into guinea pigs for isolation of tubercle bacilli.
- ***Brucella*:** Isolation of *Brucella* is attempted by inoculating cream from the milk sample on serum dextrose agar or injecting into guinea pigs. Diagnosis of brucellosis in animals can be made by demonstrating antibodies in milk by the milk ring test and the Whey agglutination test as described in chapter 35.

BACTERIOLOGY OF AIR

Air is an important vehicle for transmission of many pathogenic organisms. Humans act as a source of infection and transmit the bacteria into air through coughing and sneezing.

Therefore the examination of air to detect the number of bacteria carrying particles in air is important particularly in premises where the safe working depends on the air's bacterial content being kept at a very low level. For example in:

- Surgical theatres
- Premises where the food and pharmaceutical materials are prepared
- Hospital wards, during a suspected outbreak of cross infection

The number of bacteria in air at any given point of time depends upon various factors like:

- Number of persons present
- Body movements (higher the body movements, more is the chance of air contamination)
- The amount of disturbances of their clothing

Methods for Measuring Bacterial Content of Air

The methods devised for measuring the bacterial content of air fall into two broad categories which are as follows:

1. Methods that measure bacteria carrying particles (chiefly larger particles) settle down by gravity from air on to the exposed surface, e.g., settle plate method.
2. Methods that count the number of bacteria carrying particles in a given volume of air, e.g. the slit sampler method and air centrifuge method.

Settle Plate Method

Petri dishes containing an agar medium of known surface area are left open for 30 minutes to 1 hour. Then, the plates are incubated at 37°C for 24 hours.

- **Colony count:** Large bacteria carrying dust particles settle onto the medium. The number of colonies formed on the plate indicates the number of settled particles containing bacteria.
- Blood agar is the preferred medium for an overall count of pathogenic, saprophytic and commensal bacteria.
- Malt extract agar may be used for molds.

Slit Sampler Method

This is the most efficient and convenient method for counting the number of bacteria carrying particles suspended in a unit volume of air.

Procedure: A special equipment called "slit sampler" (Fig. 57.1) is available which has three parts—(1) an area

Fig. 57.1: Air sampler (HiMedia)

to hold a petri dish, (2) suction pump and slit, (3) outer surface has a slit of 0.33 mm width and 27.5 mm length and 3 mm depth.

- Air is sucked through the equipment at a rate of one cubic foot (28.3 liter) per minute for 10 minutes and directed onto a plate containing culture medium through the slit.
- The plate is rotated mechanically so as to allow the organisms to spread out evenly on the medium.
- The culture media are incubated and the colonies are counted. The number of colonies gives the number of bacteria carrying particles present in the air.

Acceptable Limit of Air Pollution

The upper limits of the bacterial count in air in various areas are as follows:

- 50 per cubic feet in factories, offices and homes
- 10 per cubic feet in general operation theater
- 1 per cubic feet in operation theater for neurosurgery

EXAMINATION OF FOOD

There are a number of food borne pathogens, transmitted by various sources of food (Table 57.7). They pose a significant public health problem causing morbidity and mortality.

Therefore, examination of food materials is essential to determine the numbers and types of bacteria present in order to control the standards of hygiene practices followed and also to investigate outbreaks of food poisoning.

TABLE 57.7: Agents of food poisoning and their common food source

Agents of food poisoning	Food source
Staphylococcus aureus	Ham, poultry, potato or egg salad, mayonnaise, cream pastries
Bacillus cereus	Fried rice
Clostridium perfringens	Beef, poultry, legumes, gravies
B. cereus	Meats, vegetables, dried beans, cereals
Vibrio cholerae	Shellfish, water
Enterotoxigenic *Escherichia coli*	Salads, cheese, meats, water
Enterohemorrhagic *E. coli*	Ground beef, roast beef, salami, raw milk, raw vegetables, apple juice
Salmonella species	Beef, poultry, eggs, dairy products
Campylobacter jejuni	Poultry, raw milk
Shigella species	Potato or egg salad, lettuce, raw vegetables
Vibrio parahaemolyticus	Mollusks, crustaceans

Viable Plate Count

Viable plate count (or standard plate count) is the standard method followed for bacteriological examination of food.

- **Food sampling:** (1) 10 g of food material is taken in a sterile container and is homogenized in 90 mL of sterile diluent, e.g. Ringer's solution. (2) for the food contaminated only on its surface, such as intact vegetable or fruit, 100 g of food is taken in a sterile container containing 100 mL of sterile water and then shaken well so that all bacteria present on its surface will come out and are dissolved in water.
- **Food processing:** Serial dilutions of homogenate or diluent is made, and then plated onto appropriate medium. The coliform count on MacConkey broth and differential count detecting *E. coli* can be made by the methods as described for water analysis.

EXPECTED QUESTIONS

I. Write short notes on:

1. Indicator organisms for fecal contamination of water
2. Presumptive coliform count
3. Eijkman test
4. Settle plate method

EMERGING AND RE-EMERGING INFECTIONS

Definitions

Emerging Infections

They are the infectious diseases, whose incidence in humans has increased in the past 2 decades or threatens to increase in the near future (Tables 1 and 2). These diseases, with respect to no national boundaries, include:

- New infections resulting from changes or evolution of existing organisms.
- Known infections spreading to new geographic areas or populations.
- Previously unrecognized infections appearing in areas undergoing ecologic transformation.

Re-emerging Infections

They are old infections; which were clinically silent or reduced in incidence, have again re-emerged in the community, either as a result of—(1) Antimicrobial resistance in known agents or (2) Breakdowns in public health measures. Chikungunya virus re-emergence in 2005 is the classical example (Table 2).

Drug Resistance and Re-emergence

The re-emerging infections that have increased in frequency in the last decade as a result of development antimicrobial resistance include:

- MDRTB (Multi drug resistant Tuberculosis)
- XDRTB (Extensively drug resistant Tuberculosis)
- MRSA (Methicillin resistant *Staphylococcus aureus*)
- VRE (Vancomycin resistant enterococci)
- VRSA (Vancomycin resistant *Staphylococcus aureus*)
- Beta lactamase producers
  - ESBL (Extended spectrum beta lactamase producers)
  - Carbapenemase producers
  - Amp C beta lactamase producers

Annexure-2

BIOTERRORISM—BIOLOGICAL WARFARE

Definition

Bioterrorism is a form of terrorism (unlawful use of weapon against mankind) where there is intentional and deliberate release of biological agents (bacteria, viruses, fungi or their toxins) to cause mass illness or death of people, animals, or plants.

Biologic Agents used as Bioweapons (Table 1)

The biologic agents used as bioweapons should have the following key features:

- Should produce high morbidity and mortality in the community
- Potential for person-to-person spread
- Should be of low infective dose
- Should be highly infectious by aerosol
- Lack of rapid diagnostic facilities
- Effective vaccine should not be available globally
- Potential to cause anxiety
- Availability of pathogen and feasibility of production
- Environmental stability—should have the potential to be "weaponized".

History of Bioterrorism Attacks

The use of biological agents as weapons is not a new concept. They have been used since ancient time.

- The first bioweapon used was the fungus *Claviceps purpurea* (rye ergot) by the Assyrians, in the sixth century B.C.
- The plague bacilli were used in 14th century.
- During World War I—Anthrax was used by Germany to infect the mules and horses of enemies.
- During World War II—Japanese forces used anthrax and plague against prisoners.
- 2001 USA World Trade center attacks—Anthrax spores were mailed to US media and government offices during a terrorist attack. There were four deaths.

Prevention and Preparedness

To strengthen the area of bio-defence, US government passed the 'Bioterrorism Act of 2002' soon after the 2001 anthrax attack. The emergency preparedness and response network has been made, which aims at:

- Prevention of a bioterrorism attack.
- Detection of a bioweapons with efficient laboratory systems with newer diagnostic facilities.
- Quick relief during a bioterrorism attack.

Globally various agencies are working hard to curb such problems in future. In India however, such a network is still lacking.

TABLE 1: Classification of bioweapons

Category A: These agents are the highest priority pathogens which pose the greatest risk to national security	

▪ These agents can be easily disseminated or transmitted from person to person
▪ Result in high mortality and have the potential for major public health impact
▪ Might cause public panic and social disruption
▪ Require special action for public health preparedness.
	▪ Anthrax (*Bacillus anthracis*)
	▪ Botulism (*Clostridium* botulinum toxin)
	▪ Plague (*Yersinia pestis*)
	▪ Tularemia (*Francisella tularensis*)
	▪ Small pox (Variola major)
	▪ Hemorrhagic viruses
	  • Arenaviruses: Lassavirus
	  • Bunyaviridae: Crimean-Congo virus
	  • Filoviridae: Ebola, Marburg virus

Category B: These agents are the second highest priority pathogens	
▪ Moderately easy to disseminate ▪ Result in moderate morbidity rates and low mortality rates ▪ Require specifically enhanced diagnostic capacity	▪ Melioidosis (*Burkholderia pseudomallei*) ▪ Glanders (*Burkholderia mallei*) ▪ Brucellosis (*Brucella* species) ▪ Psittacosis (*Chlamydophila psittaci*) ▪ Q fever (*Coxiella burnetii*) ▪ Typhus fever (*Rickettsia prowazekii*) ▪ Toxin: Ricin, *S. auerus* Enterotoxin B, Epsilon toxin of *Clostridium perfringens* ▪ Viral encephalitis [alphaviruses (e.g., Venezuelan, eastern, and western equine encephalitis)] ▪ Food threats: *Salmonella, Shigella, E. coli* O157 ▪ Water threats: *Vibrio cholerae, Cryptosporidium*
Category C: These agents are the third highest priority pathogens. They are the emerging pathogens, to which the general population lacks immunity	
▪ These agents could be engineered for mass dissemination in the future because of availability, ease of production, and ease of dissemination ▪ They have a potential for high morbidity and mortality rates	▪ Nipah virus ▪ Hantavirus ▪ SARS coronavirus ▪ Pandemic influenza virus ▪ MDRTB ▪ Yellow fever virus

Annexure-3

LABORATORY ACQUIRED INFECTIONS

Laboratory acquired infections (LAIs) are defined as all infections acquired through laboratory or laboratory-related activities regardless whether they are symptomatic or asymptomatic in nature.

LAIs result from occupational exposure to infectious agents. The most common route of exposure and accidental inoculation are the following:

- Inhalation (see aerosols)
- Percutaneous inoculation (needle and syringe, cuts or abrasions from contaminated items and animal bites)
- Contact between mucous membranes and contaminated materials (hands or surfaces)
- Ingestion (aspiration through a pipette, smoking or eating).

The risk-based classification of potential organisms responsible for LAIs are summarized in Table 1.

TABLE 1: Risk based classification of agents causing laboratory-acquired infections

Group	Definition	Bacteria	Virus	Fungi	Parasite
Group-1	Biological agents that are unlikely to cause human disease	No pathogenic organisms	–	–	–
Group-2	Biological agents that can cause human disease and may be hazard to workers; but are unlikely to spread to community; effective treatment or prophylaxis is usually available	▪ *Bacillus* species (except *B. anthracis)* ▪ *Clostridium* species ▪ *Corynebacterium diphtheriae* ▪ Enterobacteriaceae ▪ *Staphylococcus* ▪ *Streptococcus* ▪ *Mycobacterium* (except *M. tuberculosis*)	▪ Adenovirus ▪ Calicivirus ▪ *Coronavirus* (not SARS-CoV) ▪ Herpesvirus ▪ Influenza virus	▪ *Cryptococcus* ▪ *Candida* ▪ Dermatophytes ▪ *Aspergillus*	All clinically important parasites
Group-3	Biological agents that can cause severe human disease and are a serious hazard to workers They may spread to the community; but effective treatment or prophylaxis is usually available	▪ *B. anthracis* ▪ *Brucella* species ▪ *Coxiella burnetii* ▪ *Francisella tularensis* ▪ *M. tuberculosis*	▪ Prion ▪ LCM virus (Lymphocytic choriomeningitis) ▪ Hantavirus ▪ SARS-CoV ▪ Encephalitis virus such as: • St Louis • Japanese • West Nile • Western equine	–	–
Group-4	Same as group 3 except that effective treatment or prophylaxis is usually not available	–	▪ Lassa virus ▪ Ebola virus ▪ Marbug virus ▪ Herpes simiae virus	–	–

Annexure-4

ZOONOSIS

Zoonosis has been defined as infectious diseases that are primary infections of vertebrate animals, which can be naturally transmitted to humans.

Classification (Table 1)

Zoonotic diseases can be classified in terms of their reservoir hosts as:

- **Anthropozoonosis**: Infections transmitted to man from lower vertebrate animals.
- **Zooanthroponosis:** Infections that are transmitted from man to lower vertebrate animals.
- **Amphixenoses:** Infections that are maintained in both animals and lower vertebrate animals that may be transmitted in either direction.

More than 150 zoonotic diseases have been recognized, and the Important ones are given in the Table 1.

TABLE 1: Important zoonotic infections affecting human beings and their usual sources

Bacteria	Animals	Viruses	Animals	Fungi	Animals	Parasites	Animals
Anthrax	Herbivores	Rabies	Dogs	Zoophilic dermatophytoses		*Toxoplasma*	Cats
Plague	Rat	Yellow fever	Monkeys	*Trichophyton equinum*	Horse	*Leishmania*	Dogs
Brucellosis	Sheep, goat, camel	Japanese encephalitis	Pigs	*Trichophyton simii*	Dogs, poultry	*Taenia*	Pigs, cattle
Leptospirosis	Rodents	Kyasanur forest disease chikungunya	Monkeys	*Microsporum canis*	Dogs	*Echinococcus*	Dog
Salmonellosis	Poultry			*Microsporum equinum*	Horse	*Cryptosporidium*	Cattle
Bovine tuberculosis	Cow	Monkey pox	Monkeys			*Fasciolopsis buski*	Pigs, cattle
Endemic typhus	Rodents	Prion diseases	Cattle				Pigs
Tularaemia	Rabbits	Hemorrhagic fevers	Rodents, cattle, wild animals				
		Influenza	Pigs, birds				

Index

A

ABO blood group system 206
Acellular pertussis vaccine 248, 354
Achromobacter xylosoxidans 344
Acid-fast organisms/structures 16*t*
Acid-fast stain 16, 275, 278, 289*f*
  modifications of 16, 295
Acinetobacter 339, 343, 344
Acquired immunodeficiency syndrome (AIDS) 192, 503
Actinobacillus actinomycetemcomitans 350
Actinomadura 292, 294, 295
Actinomyces 21, 268, 292, 294*t*
Actinomycetes 293
Actinomycetoma 294, 559, 559*t*
Actinomycosis 293*f*
Activation-induced cell death (AICD) 183
Adansonian, classification of 8
Adenosine diphosphate 29
Adenoviruses 449, 526
Adhesins 232, 304, 351, 566
Aedes aegypti 486, 489, 492
Aerobes, facultative 28
Aeromonas 338
Aflatoxin 575
African tick-bite fever 391
Agar dilution method 86
Agar 43
Agglutination reaction 125
Aggregatibacter actinomycetemcomitans 350
Albert's stain 16, 54, 243, 246
Alcaligenes 344
Alginate coat 339
Alkaline bile salt agar 334
Alkaline peptone water 45, 334
Alkaline salt transport medium 333
Alloantigens 106
Alpha-fetoprotein 199, 199*t*
Alphavirus 486
  encephalitis group 488
  fever-arthritis group 486
Ames test 69, 70*f*
AMPC beta-lactamase 83*t*
Anaerobes 256
  Clostridium 256
  facultative 28
  non-sporing 256
Anaerobic cocci 268
Anaphylatoxin 178
Anaplasma phagocytophilum 392
Andaman hemorrhagic fever 384
Aniline dyes 39
Animal parainfluenza viruses 465
Anoxomat anaerobic system 50*f*
Anthracoid bacilli 254, 254*t*
Anthrax 250
Antibiogram typing 63, 325
Antibody coated bacteria test 303
Antibody diversity 119
Antibody, structure of 110*f*
Antibody-dependent
  cellular cytotoxicity 167, 176*f*, 196
  cellular dysfunction 177
Antibody-mediated 162
  immune response 167, 424
Anticitrullinated peptide antibodies 186
Antidiphtheritic serum 248
Antigen 105
Antigen-antibody reaction 121
  types of 123, 123*t*
Antigen-presenting cells 162, 163
Antiglobulin test 127
Antimicrobial susceptibility testing 83, 216, 218, 234, 301, 302, 306, 307, 341, 597
Antinuclear antibody 186, 186*f*
Anti-oncogenes 543
Anti-rabies prophylaxis 501*t*
Antiretroviral drugs 513, 514*t*
Antistreptolysin O 226
  antibodies 223, 228
Antiviral drugs 430*t*
Apoptosis-regulatory genes 543
Arboviruses 483, 484*t*
Arcanobacterium haemolyticum 249
Arenaviruses 517, 518
Arthus reaction 178
Arylsulfatase test 278
Aschoff nodules 225
Ascoli's thermoprecipitation test 252
Aseptic meningitis 466, 480, 591
Ashdown's medium 342, 342*f*
ASO test 129
Aspergillus 550, 566, 574*f*
Asymptomatic bacteriuria 587
Ataxia telangiectasia 190
Athlete foot 555
Atopy 174
Atrophic rhinitis 308
Autoantibodies 286
Autoimmune hemolytic anemias 177, 186
Autoimmunity 182, 183
Automated blood culture techniques 59
Auxotyping 63
Avian flu 462, 463

B

B cells 167
Bacillary angiomatosis 395, 395*f*
Bacillus 250
  anthracis 97, 250-254
  cereus 254, 255, 589
  sterilization control 255
Bacteremia 225, 230, 251, 258, 268, 302
Bacterial cell
  division 26
  wall 17
Bacterial colony, morphology of 54
Bacterial endotoxin 92*f*
Bacterial exotoxins 93*t*
Bacterial metabolism 28
Bacterial recombination 75
Bacterial secretory system 93

Bacterial spore 24
Bacterial taxonomy 3
Bacterial vaginosis 267, 268, 367, 368
Bacterial virulence 586
Bacterial vitamin 26, 26*t*
Bacteria-mediated endocytosis 320
Bacteriocin typing 63, 247, 279
Bacteriological incubator 49, 49*f*
Bacteriophage 454, 617
Bacteroides 268
Bannwarth's syndrome 383
Bare lymphocyte syndrome 158
Bartonella 395
BCG 282
Bence Jones proteins 115
Bengal strain 332
Beta lactam antibiotics 218
Beta lactamases, ambler classification of 83*t*
Bifidobacterium species 267
Bile aesculin hydrolysis test 230
Bile solubility 234, 234*f*
Biological safety cabinet 47*f*
Biomedical waste 612, 613*t*
Bioterrorism 627
Blastomyces 564*f*
Bloodstream infection 215, 268, 595, 608
  types of 595
Blotting techniques 77
Blueberry Muffin syndrome 473
Bocaviruses 447
Bordetella 351
Borna disease virus 526
Bornholm disease 480
Borrelia 372, 381
Botryomycosis 215, 558
Botulinum toxin 93t, 264
Botulism, types of 264
Bovine spongiform encephalopathy 523
Branched-chain DNA assay 538
Brazilian purpuric fever 349
Brill-Zinsser disease 390
Brucella 355, 358, 620
Brucellin skin test 359
Bruton disease 188
Bubonic plague 313
Bull-neck appearance 244
Bunyaviridae 494
Burkholderia 339
Buruli ulcer 283

C

California encephalitis virus complex 494
Calymmatobacterium granulomatis 316, 366
Camplylobacter 22, 361
Cancer 159
  immunotherapy 200
  vaccines 200
Candida albicans 241, 566, 567, 568f, 586
Candle jar 49, 50*f*
Capacity (kelsey-sykes) test 41
Capnocytophaga 370
Capsular polysaccharide 232, 236, 267
Cardiobacterium hominis 350
Carom coin appearance 233
Carrion's disease 396
Castaneda's biphasic medium 597
Catalase test 55, 55*f*
Cat-scratch disease 395, 395*f*
C-carbohydrate antigen 222
Cell line 477, 499
Cell wall 20
Cell-mediated 162
  immune response 103
Cellular immunodeficiencies 187*t*, 189
Central European encephalitis virus 493
Cepacia syndrome 343
Chancroid 345, 348, 348*f*
Chediak-Higashi syndrome 191, 199
Chemiluminescence-linked immunoassay 134
Chemoattractant 178
Chemoorganoheterotrophs 28
Chemotrophs 28
Cheopis index 312
Chick martin test 40
Chiggerosis 392
Chikungunya 486, 486*t*
Chlamydia trachomatis 241, 398, 403
Chlamydophila pneumoniae 401, 403
Chlamydophila psittaci 400, 403
Chromobacterium violaceum 370
Chromoblastomycosis 561
Chryseobacterium 344
Citrate utilization test 56, 57*f*
Citrobacter freundii 318
Clostridium difficile 265, 266
Clostridium histolyticum 28
Clostridium perfringens 257, 589, 616
Clostridium perfringens
Clostridium tetani 260
Clue cells 367
Coagulase test 216, 217, 217*f*
Coccidioides 565
Coiling phagocytosis 365
Colorado tick fever virus 495
Condyloma acuminatum 449*f*
Condylomata lata 373, 374*f*
Confocal microscope 12
Congenital CMV infection 439
Congenital rubella infection 472, 472*f*
Congenital syphilis 374, 379
Congenital varicella syndrome 438
Coombs test 127, 128
Coronaviruses 520, 520*f*
Corynebacteria 243
Cowpox and buffalopox virus 454
Coxiella burnetii 394
Coxsackieviruses 480
Craigie's tube 319
C-reactive protein 232
Creutzfeldt-Jakob disease 523
Cryptococcus 124, 550, 569
Cytokines 100, 103, 145, 158
Cytomegalovirus 413*t*, 419, 439, 592
Cytosolic pathway 163
Cytotoxic T lymphocytes 165

D

Dakar vaccine 493
Darling's disease 562
Daudi cells 157
Decarboxylase test 58, 58*f*
Dendritic cells 154, 155*f*
Dengue 486*t*, 491
Dermatophyte 555, 556
Desert rheumatism 564
Diarrheagenic *E. coli* 303
Dienes phenomenon 310
Digeorge syndrome 146, 189
Dimorphic fungi 550
Dinger's ring 386
Diphtheria 243
Diphtheroids 249, 249*f*
Disseminated gonococcal infection 242
DNase test 216, 217
Donovanosis 316, 366, 367
Dots-plus programme 281
DPT vaccine 248, 354
Drug susceptibility testing 280
Drug-induced hemolytic anemia 177
Drug-resistant tuberculosis 281
Dumb rabies 499, 502

E

E. floccosum 557
Eastern equine encephalitis 488
Eaton's agent 405
Eberth-gaffky bacillus 317
Ebola virus 519, 520*f*
Echoviruses 481

Ectothrix 556
Eczema herpeticum 436
Edwardsiella tarda 300
Ehrlichia 388
Eijkman test 617
Eikenella corrodens 350
Ekiri syndrome 306
Elek's gel precipitation test 247, 247*f*
ELISA 132
Elispot test 132, 132*f*
Elizabethkingia meningosepticum 344
Encephalitic arboviruses 484
Endemic syphilis 380
Endemic typhus (flea-borne) 390
Endocarditis 596*t*
Endotoxins 91, 306, 351
Energy parasites 398
Enteric fever 320, 321
Enterobacter 308
Enterobacteriaceae 298
Enterococcus 229, 230*f*
Enterohemorrhagic *E. coli* 303, 304
Enteropathy X-linked syndrome 151
Enterotoxin 212, 213, 267, 299
Enteroviruses 475, 481
Epidemic typhus (louse-borne) 390
Epidermodysplasia verruciformis 448
Epidermolytic toxin 212, 213
Epidermophyton floccosum 556, 558*f*
Epidermophyton species 555
Epifluorescence microscope 12
Epstein-barr virus 413*t*, 419, 441
Erysipeloid 297
Erysipelothrix rhusiopathiae 297
Erythema infectiosum 446
Erythema marginatum 226
Erythema migrans 382, 382*f*
Erythema multiforme 436
Erythema nodosum
  leprosum 288
Erythrasma 249
Erythroblastosis fetalis 177, 207
Erythrogenic fever 223
Escherichia coli 159, 299, 300, 301
Eumycetoma 294, 560*f*
Exotoxins 92

F

Faine's criteria 386
Febrile blisters 435
Fever, of unknown origin 598*t*, 597*t*
Filoviruses 519
Filters, types of 35
Fimbriae 23, 91
Fitz-Hugh-Curtis syndrome 239
Flagella 22, 108,
Flaviviridae 488
Flavobacterium 344
Flinders island spotted fever 391
Floppy child syndrome 264
Flow cytometry, principle of 134*f*
Fluorescent microscopy 425
Fluorescent treponemal antibody
  absorption 377
  test 378
Follicular dendritic cells 155, 169
Forchheimer spots 472
Foreign antigens 106
Formaldehyde inactivated vaccine 529
Formalin killed vaccine 314
Fragment length polymorphism 63*t*, 64
Francisella tularensis 369
Franklin's disease 116
Freund's adjuvant
  complete 107
  incomplete 107
FTA-ABS test 378
Fungi
  imperfecti 550
Fusarium species 577, 577*f*
Fusobacterium 268

G

Ganjam virus 494
Gardnerella vaginalis 243, 267, 268, 367
Gas gangrene 256, 258-260
Gas liquid chromatography 269
Gaseous sterilization 39
Gas-liquid chromatography 293
Gaspak system 51, 256
Genetic engineering 76
Genomospecies 343
Genotypic methods 63
Genotypic mixing 418
Genotypic variation 68
Germ theory of disease 3
Germ tube test 568
German measles 471
Ghon focus 274
Giemsa stain 365, 382*f*, 603
Global Polio Eradication Initiative 480
Gonococcal urethritis 242, 242*t*
Gonorrhea 239
Goodpasture syndrome 186
Graft rejection 196, 196f, 197*f*
Graft vs host disease 159
Gram stain 14, 25, 54
Granuloma inguinale 316,
Graves' disease 177, 315
Green nail syndrome 340
Guanarito virus 518
Guillain-Barré syndrome 362
Gumma 374
Guttate psoriasis 224, 225

H

H antigen 299
Haemaphysalis spinigera 493
Haemophilus 345
  aegyptius 349
  aphrophilus 349
  ducreyi 102, 348, 349
  haemolyticus 349
  influenza 237, 345, 347, 348
  parahaemolyticus 349
  parainfluenzae 349
  paraphrophilus 349
Hair perforation test 557
Halophilic vibrios 328, 337
Hand hygiene 608, 609, 610*f*
Hansen's bacilli 271
Hantaviruses 517
Hapten 105
Haverhill fever 368
Healthcare-associated infections 606
Heat tolerance test 230
Heiberg classification 328
Helicobacter pylori 136
Hemagglutination test 129, 450, 461, 472
Hemolytic disease of newborn 207
Hemorrhagic fever 493
Hendra virus 470
Hepatitis viruses 527*t*
Herpes gladiatorum 435
Herpes simian B virus 445
Herpes simplex virus 413*t*, 419*t*, 433*f*
Herpesviruses 433
Herpetic whitlow 435
Heteroantigens 106
Heterophile antigen 106
Heterotrophs 28
HFR conjugation 73
Hib conjugate vaccine 348
Histoplasma capsulatum 562, 563*f*
HIV 513, 540, 507
Hopanoids 20
Hospital acquired infections 606
Hospital Infection Control Committee
  610

Hot-cold phenomenon 212
Hoyle's potassium tellurite agar 246
Human diploid cell vaccine 501
Human immunodeficiency virus 503, 592
Human metapneumovirus 471
Human papillomavirus 419t, 447, 449
Human prion diseases 523
Humoral immune response 273, 287
Humoral immunity 406, 459
Humoral immunodeficiency 187*t*, 188
Hybridoma technique 116, 116*f*
Hyperacute graft rejection 194*f*
Hyperacute rejection 194
Hyper-IgM syndrome 189, 191
Hypersensitivity reaction 177, 179, 179*t*

I

Immune surveillance theory 199
Immunization 263
Immunochromatographic test 136
Immunodeficiency disorders 187
Immuno-electron microscopy 425
Immunoelectrophoresis 125*f*
Immunofluorescence assay 133, 133*f*
Immunoglobulins 115, 115*f*
Immunohistochemistry 134
Immunological tolerance 106, 182
Immunoperoxidase staining 425, 429
Immunoprophylaxis 202
Immunosuppressive drugs/therapy 197, 198*t*
Indole test 56, 56*f*, 308
Infant botulism 264
Infant mouse brain vaccines 500
Infantile diarrhea 303
Infectious mononucleosis 442
Infective endocarditis 340, 595
Infective syndromes 585
Influenza virus 457, 458*f*, 460
Interferon gamma release assay 279
Intermittent sterilization 33
Ionizing radiation 36
Isoantigens 106
Isopropyl alcohol 37
Izumi-fever 315

J

Japanese B encephalitis virus 488
Job's syndrome 191
Johne's bacillus 283
Junin virus 518

K

Kawasaki's disease 315
Kingella kingae 350
Kinyoun method 16, 295
Kinyoun's method 16
Kirby-Bauer disk diffusion method 84, 84*f*
Klebsiella 308, 366, 586
  granulomatis 366, 367
Klebs-Loeffler bacillus 244
Koch's phenomenon 273
Koplik spot 467*f*
Kyasanur forest disease 90

L

La crosse virus 494
Lactobacilli 268
Latent syphilis 374
Latent tuberculosis 275, 279
Latex agglutination test 126, 342
Lattice hypothesis 122, 122*f*
Lazy leukocyte syndrome 191
Lectin pathway 139, 141
Legionella 364, 366
Lemierre's syndrome 268, 269
Lemming fever 369
Lepra bacilli 285
Lepra reactions 287, 288*t*
Lepromin test 286, 290
Leprosy 290
Leptospira 372, 384
Leptotrichia buccalis 268, 269, 383*f*
Leukocyte adhesion deficiency 191
Leukocyte esterase test 303
Levinthal's agar 347
Levofloxacin 281
Ligase chain reaction 60, 278
Lipopolysaccharide 19, 91, 98
Lipoteichoic acid 222
Listeria monocytogenes 295
Lithotrophs 28
Live attenuated vaccine 202, 254
Loeffler's serum slope 45, 246, 246*f*

Nocardia 292-295
Nomen system of classification 355
Noncholera vibrios 329
Nondiphtherial corynebacteria 249
Nongonococcal urethritis 242, 242*t*, 399
Nonhalophilic vibrios 328
Nonneutralizing antibodies 490
Nonphotochromogens 283
Nonsporing anaerobes 266, 267
classification of 266, 266*t*
Nontreponemal tests 376
Nontuberculous mycobacteria 271, 277, 282
Runyon's classification of 283
Nontypeable *Haemophilus* strains 347*t*
Nontyphoidal salmonellae 317, 326, 327
Nonvenereal treponematoses 379, 380
Nucleic acid
amplification 60
probe 77, 426
sequence-based amplification 60, 278
Nugent's score 367
Nutrient agar 44
Nutrient broth 44, 314

O

O'nyong-nyong virus 487
Oakley-Fulthorpe procedure 124
Oncofetal antigens 199
Oncogenes 542
Oncogenesis 545, 545*f*, 546
Oncogenic viruses 542, 542t
Onychomycosis 567*f*
Ophthalmia neonatorum 240, 400
Opportunistic mycoses 550, 551, 566
Opsonin 113
Opsonization 142, 176
Optochin sensitivity 234, 234*f*
Oral cholera vaccines 336
Oral live attenuated vaccines 336
Oral polio vaccine 203, 418, 477
Oral rehydration solution 307
Oral thrush 567*f*, 600
Orbital cellulitis 571*f*
Organotrophs 28
Orientia tsutsugamushi 392
Ornithodoros species 381
Ornithosis 400
Oropouche virus 494
Oroya fever 396
Orungo virus 495
Oxidase test 55, 56*f*, 307

P

Pandemic influenza virus 463*f*
Panton valentine toxin 212
Papillomaviridae 447
Paracoccidioides brasiliensis 565
Paraffin bait technique 295
Parainfluenza viruses 464
Paramyxoviridae 463, 464*t*
Parechoviruses 481
Parvovirus 446
Passive agglutination test 127*f*
Passive immunization 260, 431, 500, 536
Pasteurella 369, 370
Paul Bunnell test 106, 126, 127, 444*t*
Pediculus humanus 381
Pemphigus vulgaris 177
Penicillium 566
marneffei 575, 576*f*
Pentose phosphate pathway 29
Peptidoglycan 18, 212, 225
Peptostreptococcus 268
Perforins 166
Peripheral tolerance 182
Pertussis
toxin 351
Pfeiffer's bacillus 345
Phagocytes 99
Phagocytosis 113, 154, 154*f*, 414
disorders of 187*t*, 191
Pharyngoconjunctival fever 450
Phenyl pyruvic acid test 59
Phlebotomus pappatasi 494
Phosphatase test 216, 217, 620
Photochromogens 283
Phototrophs 28
Phytohemagglutinin 511
Picobirnaviruses 526
Picornaviruses 475
Pike's medium 226
Pike's transport media 226
Pityriasis versicolor 553
Plague 311
Plasma cell 110, 132, 152
Plasmid 67, 67*f*, 68
Pleomorphism 310, 314
Plesiomonas 316
Pleurodynia 480
Pleuropneumonia like organisms 405
Pneumatocele 215
Pneumococcus
Polio eradication 479
Poliomyelitis 475
Polyacrylamide gel electrophoresis 135
Polyclonal B cell activation 184
Polymerase chain reaction 5, 60
Polymorphonuclear leukocyte 155
Polymyxins 341
Polyomaviridae 447

Ponder's stain 243
Pontiac fever 365
Porphyromonas 269
Porter's disease 251
Post-measles encephalomyelitis 468
Post-streptococcal glomerulonephritis 225, 226, 226*t*, 228
Pour-plate method 49, 49*f*
Powassan encephalitis viruses 493
Poxvirus 451, 451*t*, 453
Preisz-Nocard bacillus 249
Prevotella 268
Prion diseases 523
